Abstract

Background: Enrichment activities are essential for enhancing the psychosocial well-being of older adults living in residential aged care homes. There has been increasing interest in using digital technology for enrichment, but the implementation of technology requires careful support and enablement from staff to ensure that residents experience the intended benefits.

Objective: This study aimed to understand how care staff facilitate aged care residents' use of the Tovertafel ("magic table" in Dutch), a technology that projects images onto a tabletop to enable groups of people to play games. The study further aimed to understand the benefits arising from the Tovertafel when facilitated by staff.

Methods: We conducted a field study in 1 residential aged care home in Queensland, Australia. The methods included semistructured interviews with the staff and residents about their experiences with the Tovertafel, observations of 4 sessions in which the residents and staff played Tovertafel games, and a diary completed by the staff after Tovertafel sessions. Data were analyzed through reflexive thematic analysis.

Results: We developed 3 themes through our analysis. Theme 1 highlights the need for the staff to overcome physical and personal barriers before Tovertafel sessions could take place. These included a lack of a dedicated space for playing Tovertafel games and the residents' reluctance to attend Tovertafel sessions. Theme 2 highlights how the staff used creative strategies to make Tovertafel sessions successful. These included helping the residents learn how to interact with the games; adapting the activity to suit the capabilities of the residents; sustaining engagement by choosing appropriate games; and using prompts, questions, and storytelling to make the games more engaging. Theme 3 describes the benefits and outcomes that arose from staff-supported enablement of the Tovertafel, including participation in an enjoyable physical activity, socialization, and reminiscence.

Conclusions: This study suggests that the Tovertafel provides opportunities for aged care staff to engage in creative play and personalization catering to residents with different capabilities. However, the benefits arising from the Tovertafel are unlikely to be achieved without substantial facilitation from the staff, who play a key role in enabling the participation of the residents. Sustaining the engagement of the residents is important during Tovertafel activities and can lead to beneficial outcomes.

Introduction

Background

In 2023, a total of 185,000 Australians aged ≥65 years lived in residential aged care homes [1]. Older individuals usually move to residential care when they require high levels of support to enable appropriate clinical care alongside holistic well-being [2,3]. Holistic well-being refers to addressing residents' physical, psychological, and social needs [4]. To promote physical well-being, staff members from lifestyle teams support residents with activities of daily living, such as bathing, dressing, and eating, and enable them to participate in physical activities through exercise programs.

To promote psychological and social well-being, staff members provide an array of enrichment activities, such as art, gardening, music, games, and excursions. These activities are important for encouraging social interaction and preventing boredom [5], enhancing residents' quality of life [6], and promoting a sense of continuity, particularly when residents engage in activities that interest them [7]. However, activities in residential care are often group based and may not cater to the needs of all residents [6], particularly when there is diversity among residents regarding individual interests [7], cultural background [8], or functional and cognitive capabilities [9,10].

Recent years have seen an increasing uptake of digital technologies for enrichment in residential care homes [11]. Technology-based activities can both expand the range of available options and enable new experiences of joy and social engagement [12]. For example, immersive virtual reality (VR) offers the possibility of virtually "traveling" to distant locations, revisiting places from the past, and remotely attending concerts [13,14]. When used appropriately and in a way that demonstrates person-centered care, technology-based activities can address the individual needs and goals of residents, including those with cognitive impairment [11].

However, research has identified that appropriately trained staff are often required to enable the effective use of technology in aged care [15]. Residential care staff are known to be dealing with high workloads [16], and there is a risk that facilitating technology may add to this load. While technology facilitation can be enriching when it involves meaningful care work [17], significant work in setting up and manipulating the technology can be an unwanted burden that limits the use of the technology [18,19]. Therefore, evaluating the demands placed on care staff, along with the potential benefits of using technology with residents, is an important consideration when justifying the use of technology as part of a care home's lifestyle and social calendar.

The Tovertafel

This study focuses on staff involvement in enabling the Tovertafel ("magic table" in Dutch), a commercial system that enables groups of people to play games by tapping on moving images projected onto a tabletop [20]. The games vary in difficulty, from simple activities such as sweeping leaves or popping bubbles to more advanced puzzles and team-based games that require cognitive and social engagement. While the Tovertafel is aimed at providing stimulation for care home residents living with dementia, it can be used by residents with various levels of cognitive impairment. Table 1 provides examples of Tovertafel games.

Table 1. Examples of Tovertafel games.

Game name	Description
Leaves	Players use arm movements to sweep piles of leaves from the tabletop.
Football	Players try to score goals at either end of the table by tapping a soccer ball.
Music Box	Players tap on musical notes rotating around a music box in the center of the table. The notes play piano sounds when tapped. At the end of the game, the music box reveals a spinning ballerina and plays a song.
Rhymes	Players tap on feathers to reveal the words of a nursery rhyme, which can then be read aloud.
Sayings	Players tap on moving bubbles to reveal a phrase or saying, for example, "Never look a gift horse in the mouth."
Silverware	Players wave their arms over images of cutlery to simulate polishing a dinner set. Once all pieces are polished, plates and food appear on the tabletop, simulating the table being laid at dinner time.
The Veggie Patch	The game simulates gardening by requiring players to plant and water vegetables. Seed packets move over the table, causing vegetables to be planted when tapped. There are also moving clouds and sunbeams, which cause the plants to grow when tapped.

A small number of studies have examined the use of the Tovertafel in residential aged care. These studies have primarily focused on identifying benefits and drawbacks of the technology. Good et al [21] interviewed care staff about the perceived benefits of the Tovertafel for residents living with moderate to advanced dementia. Staff felt that using the Tovertafel had several benefits, including improved communication between staff and residents and short-term improvements in residents' mood. However, the Tovertafel was rarely used by residents without initiation from carers or loved ones, and residents with dementia could only use the Tovertafel for a short time because of impaired concentration. A study by Talman and Gustafsson [22] identified benefits of the Tovertafel for people living with intellectual disabilities. However, these findings may not be applicable to aged care. The Tovertafel's official website lists various studies that have been conducted to validate the system, but most are unpublished, originate from master's theses, or require readers to contact the company to obtain further information [23]. Other than the studies mentioned earlier

[21,22], the only publicly available study evaluating the Tovertafel is in Dutch [24].

While the impact of the Tovertafel may be positive, there has been limited examination of the care strategies required to facilitate the participation of residents in the activity. There is also limited understanding of how staff work to overcome issues that may impact the engagement of aged care residents with the Tovertafel. Research is needed to better understand how staff facilitate the Tovertafel activity and to inform decisions about using this technology, given the limited resources available in many residential aged care homes.

Objectives

This study aimed to address the following research questions:

1. How do care staff enable residents' use of the Tovertafel in residential aged care homes?
2. What benefits arise from staff-supported enablement of the Tovertafel?

Methods

Ethical Considerations

All procedures in this study received approval from the University of Melbourne's Human Research Ethics Committee (ID 12900) and the Bolton Clarke Human Research Ethics Committee (approval 230001). Our study involved participants who were either staff or residents from one aged care home in Australia. The staff participants signed a participant information sheet and consent form (PICF) and received an Aus $20 (US $13.37) gift voucher as a token of appreciation.

The care home residents who participated in the interviews were provided with a PICF that included pictures of Tovertafel games, along with a textual description of the technology. Some of these residents were shown a YouTube video of the Tovertafel if they were unable to understand its functionality from the PICF alone. The residents who agreed to be interviewed provided informed consent by signing the PICF and received baked goods as a token of gratitude. Some residents living in the memory support unit of the care home did not have the capacity to consent, so interviews were not sought about their experiences with the Tovertafel. However, we observed the sessions in which these residents participated and collected observational notes about their use of the Tovertafel, without capturing personal or identifying information, in line with the ethics approvals for the project.

All data from the study was storied securely in password-protected filing cabinets or secure cloud-based storage to protect the confidentiality of the data. All transcripts were anonymized, and names were replaced with pseudonyms to protect participants' privacy.

Study Design

We conducted a field study to investigate how the Tovertafel was used in 1 Australian residential aged care home. The study involved semistructured interviews, observations, and a participant diary. We chose these methods to gain in-depth insight into staff members' experiences of facilitating the Tovertafel and to understand how this facilitation elicits benefits for residents. All procedures were developed by the research team, drawing on our previous experience with the chosen methods [25,26] and our experience of conducting fieldwork in aged care [8,27,28].

First, the staff who were familiar with using the Tovertafel were interviewed about their experiences of using the system, the strategies that they had used to make the activity successful, and the perceived benefits. We also conducted interviews with the residents who had used the Tovertafel, provided they had the capacity to give informed consent and provide feedback. These interviews sought to understand what the residents liked about the activity and what they found challenging. The interview schedule for the residents contained simple questions to avoid overburdening them.

Second, we observed 4 activity sessions, each lasting 45 minutes, in which small groups of staff and residents played a variety of Tovertafel games. These sessions were scheduled by the lifestyle team of the care home as part of the usual activity schedule. The observations enabled us to understand how the Tovertafel was used in practice, what the staff did to make each session successful, and how the residents responded to the activity.

Third, the staff leading the Tovertafel activity were asked to complete a diary after each session. The diaries invited further reflection on the use of the Tovertafel, including the views of the staff about the impact of the Tovertafel on the mood of residents, what worked well, and what the staff found challenging about the session (refer to Multimedia Appendix 1 for the diary design). The staff were asked to complete diary entries after each Tovertafel session to capture their experiences as close to the time of delivery as possible.

Table 2 lists the observed Tovertafel sessions, the number of people involved, and the timing of diary entries completed by the staff members.

Table 2. List of the Tovertafel sessions examined.

Study Site

Our study took place at 1 residential aged care home of a not-for-profit aged care provider in Queensland, Australia, in 2023. The home provides care for approximately 80 residents divided across 3 residential wings: a memory support unit for residents with severe cognitive impairment, a nursing home area for other residents with high care needs, and a hostel area for residents with lower care needs. The home had 112 staff at the time of our study, including, for example, administrative staff, nurses, managers, and housekeeping staff. The home had 2 staff members who oversaw lifestyle activities: 1 diversional therapist and 1 lifestyle activities coordinator. These staff members were supported to run activity sessions by nursing and personal care staff, depending on availability and the number of people required.

The residents at the home predominantly follow a daily routine with fixed times for meals and personal care. Enrichment activities are scheduled around this routine. The lifestyle activities coordinator prepares a monthly activities calendar, which is distributed to residents on paper. Each day has an activity in the morning and another in the afternoon. Activities last between 45 and 60 minutes, and the residents are free to attend as they please. All activities are announced by staff over a public address system transmitted across the 3 residential wings.

The care home has a large room for providing lifestyle activities. At the time of our study, this room was undergoing renovation. Because of this, the equipment for the Tovertafel had been installed in the dining areas of the memory support unit and the nursing home.

During this study, the Tovertafel activity was scheduled in the activities calendar, allowing the residents from the memory support unit and the nursing home to participate (Table 2). The residents from the hostel area were also welcome to participate. The staff had been using the Tovertafel for 2 years, having received the device as a gift from a benefactor in 2021, but it had not been included in the activities schedule for >6 months before this research. The staff had not received formal training on how to use the Tovertafel. Instead, they learned on the job. After the Tovertafel was first installed in the home, the diversional therapist downloaded a PDF of the system's user manual to understand how the device should be operated.

Participant Recruitment

The staff members were invited to participate in the study if they were familiar with the Tovertafel or if they were scheduled to help facilitate the sessions during the study period. All 6 staff members who met either of these criteria agreed to participate. Volunteers and family members were also eligible to participate in the study, but none were present when data were collected.

Procedure

All procedures were carried out by 2 researchers (RMK and AM). Two fieldwork visits, each lasting 4 days, were conducted in June 2023. Both researchers spent several days on-site before and after the Tovertafel sessions, providing opportunities to learn about the social routines of the care home [29]. The researchers took photographs of the setting, without capturing images of the residents or the staff, and tested the Tovertafel games to understand what they involved. The dates and times of the observed sessions are provided in Table 2. The researchers created private, written fieldnotes after each day of the study to record their experiences and personal reflections about the care home.

During the first fieldwork visit, the researchers interviewed the staff members about their experiences with the Tovertafel and observed 2 Tovertafel sessions in the memory support unit. The researchers conducted nonintrusive observations of each session, observing the staffs' and the residents' interactions around the Tovertafel and with each other, from 2 to 3 meters away. The researchers took notes about which games were played in each session, what the staff did to facilitate the activity, and how the residents responded to the Tovertafel, including emotional responses and social interactions. All observations of emotional responses were noted in a free-text form, rather than using a predefined behavioral grid. The staff member in charge of each session was requested to fill out the research diary after they had facilitated the activity. All diary entries (5 in total) were completed by the coordinator of the lifestyle activities in the

care home, who attended all the Tovertafel sessions examined during the study.

The first fieldwork visit was followed by a 2-week gap during which the researchers were off-site. Two Tovertafel sessions were scheduled by the staff during this time (Table 2). These sessions were not observed by the researchers, but the lifestyle activities coordinator completed the diary after each one.

During the second fieldwork visit, the researchers conducted observations of 2 Tovertafel sessions in the nursing home and invited the residents to provide feedback through interviews after each session. Follow-up interviews were conducted with the staff who had facilitated the sessions.

Analysis

Data consisted of interview transcripts, observational and fieldwork notes, photographs, and diary entries. Interviews were transcribed using a professional transcription service. Data were analyzed using the 6 phases of the approach to reflexive thematic analysis by Braun and Clarke [30]. Reflexive thematic analysis is interpretivist and acknowledges that the subjectivity of the researcher can be a valued analytical resource, while also recognizing that the analysis is influenced by the positionality of the researcher [31]. This analysis was led by RMK, whose position is that technology has the potential to enrich the lives of people living in residential care but risks becoming an unnecessary burden, particularly if the technology is not well designed for this setting [17,26]. This position informed the analysis by highlighting both the burdens involved in enabling the Tovertafel and the enriching aspects of the work, particularly when it provided the staff with opportunities to enhance the activity for the residents.

Following the 6-phase approach by Braun and Clarke [30], RMK first read through the data before inductively creating semantic and latent codes at the sentence level [31]. RMK collated the codes into potential themes that captured interpretations of the problems the staff had faced, the ways that they facilitated sessions, and the perceived benefits of the Tovertafel. The analysis was discussed several times with AM, who iterated the themes based on her involvement in the data collection. RMK then drafted the themes into an initial version of the paper, which was discussed and reviewed by all authors [32]. This team input supported a critical and balanced perspective on the Tovertafel activity. After receiving feedback from peer reviewers, the themes were revised and reorganized to strengthen the interpretations.

In the following section, we present 3 themes. These are organized chronologically, as the themes we developed align with a before-during-after framing of the activity and reflect the temporal ordering of actions conducted by the staff when facilitating the Tovertafel sessions. The first theme highlights the need for the staff to overcome physical and individual barriers *before* initiating the Tovertafel activity. The second theme reveals the importance of creative care from the staff *during* Tovertafel sessions. The third theme details the benefits and outcomes *arising from* staff-supported facilitation of the Tovertafel. Verbatim quotes are used to illustrate findings, with pseudonyms and roles at the care home used to identify participants. Descriptions of the residents' emotions or reactions to the activity are based on observations by the researchers or entries made in the staff diaries.

Results

Participant Characteristics

All 6 staff members interviewed were women. The interviews lasted between 15 and 38 (mean 30, SD 8.7) minutes. Table 3 lists participants' pseudonyms, roles, and time at the workplace for the staff participants. Each Tovertafel session was led by Corina, the lifestyle activities coordinator, along with at least 1 other staff member.

Table 3. List of interviewees.

Pseudonym	Gender	Role	Time at the workplace	Time in current role	Interviewed during the first fieldwork visit	Interviewed during the second fieldwork visit
Anne	Woman	Care home manager	20 y	4 y	✓	
Brenda	Woman	Diversional therapist	11 y	4 y	✓	✓
Corina	Woman	Lifestyle activities coordinator	4 mo	4 mo	✓	✓
Diane	Woman	Special care unit nurse	16 y	16 y	✓	
Ellen	Woman	Personal care worker	11 y	11 y	✓	
Fiona	Woman	Enrolled nurse	8 y	3 y	✓	
George	Man	Nursing home resident	N/A[a]	N/A		✓
Herbert	Man	Nursing home resident	N/A	N/A		✓
Ingrid, Julie, and Karen	Women	Hostel residents (interviewed together)	N/A	N/A		✓

[a]Not applicable.

In addition, 5 residents (2 men and 3 women) were interviewed after the Tovertafel sessions. These interviews lasted between 10 and 19 (mean 14.3, SD 4.5) minutes. Other residents were approached for the interview but either declined to provide feedback, were unable to participate because of severe communication impairments, or were occupied with personal care activities.

Theme 1: Initiating Tovertafel Sessions Required Attending to Physical and Personal Barriers

Summary

Our analysis showed that the staff needed to overcome multiple barriers before running the Tovertafel activity. These included the lack of a dedicated space for play and the need to address residents' uncertainty about joining the activity. These barriers reflect the physical and personal challenges associated with using group-based digital technology, such as the Tovertafel, within residential care homes. We provide further explanations of physical space and perceptions of technology as subthemes in the following sections.

Physical Space: The Care Home Lacked a Dedicated Space for Play

At the time of our study, the care home lacked a dedicated activities space because of an ongoing renovation in the activities room. All group activities had to take place in other communal areas.

Equipment for the Tovertafel system, including an electrical connection and a ceiling bracket, had been installed in the dining areas of the memory support unit and the nursing home. These areas were typically set up with tables and chairs in preparation for mealtimes. To make each space suitable for the Tovertafel activity, the staff had to reconfigure the furniture to create a larger table suitable for the residents to sit around.

The staff did not feel that this practical work was especially burdensome, although it did require additional effort. As part of the setup, the staff also placed a white cloth over the table for use as a playing surface, after noting that the games were hard for some residents to see without using the tablecloth. This was because the wooden tabletops had not been designed for use with the Tovertafel and tended to absorb the projected images, making a lighter surface necessary. In addition, the dining areas had large windows that let in considerable sunlight, making it harder for residents to see the projections if the tablecloth was not used:

> *The setup doesn't take that long...but one thing I found was that the graphics were a bit too light. So maybe it needs to be a certain colour that it projects onto. Because I noticed that with a few of the games, [the residents] did struggle to see what it was.* [Diane, care nurse]

The residents noted that they were hesitant about attending Tovertafel sessions because of the lack of a dedicated space for play. As noted earlier, the activities room at the care home was undergoing renovation. The residents from the hostel area where the residents had lower care needs—were invited to join the activities that took place in the nursing home and memory care unit. However, they expressed reluctance to enter these areas and felt that that it would be better if the Tovertafel was in a shared activities room:

> *I was wondering if it's possible to have that in the activity room. More people might go then...a lot of people down here don't like going into the nursing home.* [Julie, hostel resident]

In addition to needing to overcome physical space barriers to initiate the Tovertafel sessions, the staff also had to ensure that they were able to reset the space at the end of each session. We observed that there was a risk of conflict if the chairs and tables were not rearranged in the same order as before. This was because specific residents could not be seated together, and the staff needed to place the tables carefully to minimize extra work for the care and culinary staff during mealtimes. This situation also meant that the Tovertafel could not be left available for the residents to use at their convenience. As highlighted in previous work [21], the staff thought that the system might be used more often if residents could use it with visiting family members, without the need for staff assistance.

Perceptions About Technology: Residents Were Often Reluctant to Join Tovertafel Sessions

A second barrier that the staff had to overcome was the reluctance of the residents to join the sessions. The staff found it challenging to encourage the residents to attend the Tovertafel sessions because many were not interested in technology-based activities:

> *I find they're not really interested in technology as a lot of the residents have farming backgrounds. They were used to milking the cows and doing all the farm work.* [Ellen, personal care worker]

> *People tend to go "under cover" when you mention the word technology.* [Corina, lifestyle activities coordinator]

In addition, the residents were often uncertain about what the Tovertafel involved if they had not seen it before. Most of the residents we encountered spoke English as their first language, but the word "Tovertafel" lacks obvious meaning for those who do not speak Dutch. The staff found that describing the Tovertafel as "the table game" or "something you play with your hands" was more effective, though still challenging without demonstrating the activity in person.

Because of this, the staff sought to increase attendance by going to the rooms of the residents before sessions took place to explain what the activity would involve and to assure the residents that it would be enjoyable. The staff also approached the residents who were in the nearby common areas when the activity began and asked them if they would like to give the activity a try. The staff felt this was different from other frequently facilitated activities (eg, choir and concerts), which the residents did not need encouragement to attend.

The issue of attendance was important because the staff felt that the Tovertafel worked best with groups of 4 to 6 players. Having 4 players was seen as too few to make the games enjoyable. This meant that achieving enough players was important for

the activity to be successful. The staff told us that the Tovertafel had not been used for some time before the study because attendance had been poor:

> *We have used it before, but we reached a stage where we weren't getting a lot of interest. So, I've taken it off the activity calendar for a time. We just weren't having the numbers turn up to the activity.* [Brenda, diversional therapist]

The staff were also conscious that running the activity too often with the same people risked creating disinterest. This view was echoed by the residents:

> *I think if we played it every day, it might get boring. Once a week, that's no problem.* [George, nursing home resident]

To initiate the Tovertafel activity, the staff needed to be aware of which residents were available to join, how many were willing to participate, and had to encourage those who were available to attend. Addressing these social dynamics was challenging and time consuming but was essential to ensure that sessions had sufficient participants to make the games worth playing.

Theme 2: The Staff Used Creative Care Strategies to Guide the Tovertafel Sessions

Summary

This theme highlights how the staff creatively enabled the use of the Tovertafel *during* the activity; that is, once the staff had created the conditions for a Tovertafel session by arranging the play area and encouraging the residents to attend, additional work was needed to make the sessions successful. We observed that the staff used creative approaches to help residents learn the activity, enable the continued participation of the residents, and sustain their engagement. Each of these activities required differing forms of creativity, which are described in the subsequent sections.

Selecting Gentle Games to Enable Initial Learning

At the start of each session, we observed that the residents were typically unsure what the Tovertafel was and what it involved. In 1 diary entry, Corina, the activities coordinator, similarly noted that the residents were hesitant at the beginning of a Tovertafel session but became more confident once they understood what to do:

> *The mood was a bit daunting and [residents were] unsure what was going on but once we got started the mood changed and [they] became interested.* [Corina, lifestyle activities coordinator, diary excerpt, session 2]

This highlighted the need for the staff to help the residents learn how to use the Tovertafel. The staff had identified a creative way to achieve this learning. At the start of each session, they chose to leave a simple game running on the tabletop while helping the residents join the activity. The staff typically chose the game Leaves for this situation. This game involves sweeping leaves from the tabletop using arm movements. We observed that playing with the leaves helped the residents to understand what would happen if they touched the images. Changes in the leaves were both noticeable and easy to trigger, helping the residents understand how the Tovertafel reacts to their movements.

In this way, starting each session with a gentle game provided opportunities for social learning, whereby the residents learned about the activity through watching others. In session 2, we observed a resident who repeatedly exclaimed that she could not join in because she "didn't know what it was all about." She eventually began playing after watching the interactions of other residents and after receiving encouragement from staff.

These instances highlight that creative work was needed to make the residents feel comfortable at the outset of each session. They also reveal that the staff were not simply supervising the activity. Rather, they were central to making the residents feel at ease and actively encouraged the participation of the residents during the sessions.

Developing Creative Solutions to Ensure Safe Participation

Creativity was evident in the way that the staff developed solutions to other problems that hindered the participation of the residents. For example, some residents found it challenging to trigger a response from the Tovertafel because of mobility impairment. Many could not stand up without assistance and therefore could not reach across the table, while others had difficulty moving their hands or arms.

Recognizing this, the staff had cut up a "pool noodle" (ie, a cylindrical flotation device made of foam) into pieces, which the residents then held to extend their reach and trigger the Tovertafel more easily:

> *Some [residents] have problems with their arms, or they've hurt their elbow in some way. So having the pool noodle, they don't have to reach. And a lot of residents tire very quickly when they're using the arms.* [Brenda, diversional therapist]

The staff were conscious that some residents might experience motion sickness when using the Tovertafel. In session 2, the staff paid close attention to a resident who was known to experience vertigo in response to moving images. The staff described the importance of attending to visual cues, such as body language and facial expression, while running the game to ensure that the residents remained safe. In this way, the staff exhibited creative care by monitoring for signs of distress during the games and changing to a simpler game if required:

> *You need to go by the visual cues and that's probably the advantage of Tovertafel. It's a visual reaction. And it can depend day to day on that resident, with how they're going to interact in an activity or with the Tovertafel.* [Anne, care home manager]

Sustaining Engagement by Choosing Appropriate Games

The importance of choosing games was mentioned repeatedly by the staff during the interviews. We observed that the staff always took responsibility for selecting games, using a remote control to pick games from the Tovertafel's menu system.

The staff explained that choosing appropriate games was essential to sustain the engagement of the residents. One reason was that the staff felt that there needed to be a good match between the games on offer and the physical or cognitive ability of the residents in attendance:

> *[It] depends on who you've got present in the session, because they've all got varying attention spans.* [Anne, care home manager]

In addition, the games needed to be relevant to the interests of the residents; otherwise, the sessions risked becoming boring. The staff explained how this risk could be mitigated by choosing games with features that appealed to the residents. Some Tovertafel games replicate tasks such as gardening and cooking. These games were perceived as engaging because they are modeled on familiar leisure activities. For instance, the staff often selected the Veggie Patch game because many residents were interested in gardening:

> *The gardening game is one where many of the ladies enjoy gardening, so we will do that and ask what they used to do in their garden. There's one person who got very engaged by that. She loves gardening and that's one way to try and get her to engage in the game because gardening was her hobby.* [Brenda, diversional therapist]

Sometimes the staff chose games that were known to be exciting and avoided games that they thought were boring. This was established through trial and error, as well as through verbal and nonverbal feedback from the residents. The staff also switched between games based on the current state of the residents. For example, if residents appeared to be losing interest in a gentle game, staff would switch to one involving physical activity to help engage them:

> *I find if they play it for too long, they get a bit tired of it and they get a little bit bored. So that's why you've got to change to a different game, just to change the mood. It seems like they like something a bit quicker as well, more so than something that's a little bit slow and repeated.* [Corina, lifestyle activities coordinator]

Finally, the staff had identified that staying with the same game for too long risked creating boredom among the players. Changing Tovertafel games during a session was essential to counter this risk, and the staff typically spent no longer than 3 to 5 minutes on each game. Tovertafel games have various difficulty levels, and some were seen as too simple to be played for more than a few minutes. The staff tried to introduce variety by including different types of games within a session, either by manually choosing games or using the Tovertafel's built-in shuffle function, which moves through games in a randomized order:

> *I don't stay on one game for too long, like maybe five minutes. Or I gauge by watching the people around the table and if they're disengaging or not finding it interesting enough, I'm like, okay, let's switch another game now. You know, to try and give them a bit of variety. And to keep their focus.* [Brenda, diversional therapist]

Using Prompts, Questions, and Storytelling to Make the Games More Engaging

A final creative strategy was the use of different spoken techniques to keep the residents engaged. Sometimes this involved gently prompting the residents. For example, a resident in session 4 was observed to be falling asleep during the game. The staff offered words of encouragement—"Come on George," "Wake up George"—to keep him interested. In session 5, a resident felt that she "wasn't doing it right" and stopped interacting with the game. A staff member provided gentle reassurance, saying "No, you're doing a good job," which encouraged her to become involved again.

Beyond this gentle prompting and encouragement, the staff tried to keep the residents' attention on the activity by creatively responding to elements of the games with questions that encouraged interaction. For example, during the Rhymes game, the staff chose to read each rhyme aloud and then asked the residents questions about them. These questions were not part of the game but were added by the staff to make the activity more engaging. In 1 instance, after seeing a rhyme from the song "Rock-a-bye baby," the staff asked the residents if they knew the rhyme and encouraged them to sing along. During the interviews, the staff explained that this was another technique to maintain the residents' focus:

> *To make it work, I keep communicating with the residents and try not to get them off track. Like, you know, just make them stay involved. Otherwise, they're going to drift off and get sidetracked with the game.* [Corina, lifestyle activities coordinator]

Other games involved solving puzzles to reveal pictures of places or animals. The staff used these as opportunities to invite conversation about the past, asking the residents questions such as, "Have you ever been to New Zealand?" or "Did you used to have chickens in your garden?" These questions prompted the residents to talk about their lives. Staff members noted that specific games provided inspiration for these conversations, leading to positive outcomes:

> *What I try to do is to get them to share their stories, so for example when we play the music box game, I might ask them if they had a music box when they were younger. The game with silver polishing is something they would have done when they were younger. You can ask them about that, ask who they had [over] for dinner and what they used to eat.* [Brenda, diversional therapist]

These behaviors were creative techniques that had been instigated by staff members. They were not a standard part of the Tovertafel games, nor were they part of any training that the staff had received. Rather, they were strategies that staff had found to work well and represented the attempts of staff members to build on the basic elements of the Tovertafel games. This appeared to make the activity more active and engaging, as opposed to one in which the residents passively interacted with the system without understanding what they were doing.

Theme 3: Staff Creativity Fostered Benefits and Outcomes

This theme highlights 3 benefits arising from the staff-supported enablement of the Tovertafel. These included moments of joy and fun from participating in a physical activity, opportunities for socialization with other residents, and reminiscence prompted by elements of the games.

Participating in a Fun Physical Activity

The staff universally viewed the Tovertafel as a positive activity for the residents, and in their view, the benefits outweighed the work involved in setting up and running the technology.

The staff described how keeping the residents engaged was important for enjoyment, otherwise attendees would receive limited value from the activity. Through supporting the residents to use the Tovertafel, we observed that the staff were able to elicit moments of joy and laughter, particularly when playing games that involved considerable physical activity. For example, in 1 diary entry, Brenda noted a positive outcome from the session:

> *Happy, smiling during the Tovertafel, lots of laughter. There was a change, they were feeling unsure but once participating their mood became more alert and wanted to give it a go.* [Brenda, diversional therapist, diary excerpt, session 3]

A related benefit was that the Tovertafel encouraged physical activity through the use of the hands and arms. The staff viewed this as a rare opportunity for the residents to engage in gentle exercise, as illustrated by the following comment:

> *There is a whack-a-mole game, and I like that because we've got people with mobility issues and so it's good exercise for them.* [Fiona, enrolled nurse]

Encouraging Social Interaction Between Residents

The Tovertafel provided an opportunity for the residents to socialize with others in the care home. We observed that, outside of mealtimes or scheduled activities, many of the residents would either be watching television or spending time alone in their room. The residents commented on how they enjoyed the social aspects of the activity:

> *I think it's more of a social occasion, when you play games or whatever you play, you can get to know people that way and everybody has different characters, you know what I mean?* [George, care home resident]

The staff felt that the Tovertafel enabled socialization in a unique way by encouraging residents to interact with people they might not usually engage with:

> *It gets them together, you know, like having a chat. So, there's just that bit more interaction. I think it's way better than the TV. And compared to our trivia games, not everyone gets involved in the trivia. Whereas with [Tovertafel] you can involve most of them. And even if they don't want to play it, at least they might just come and watch. They're still interacting in some way, you know?* [Diane, special care unit nurse]

As Diane noted, some residents did not always want to play with the Tovertafel, preferring to sit and watch. Others attended the sessions but were unable to take part because of physical impairment. The staff believed that the Tovertafel still offered a positive opportunity for these residents to socialize, either by watching the activity or by taking on a supporting role in the games. One staff member explained as follows:

> *The ones who honestly can't play, I think it's a good idea, even if they are there to join in and give them something to do, just remember a score or help out because then they are participating and joining in as well. So that's a good thing. You're not inviting them to sit there and fall asleep. The whole idea of it is to keep them inspired, just to let them know that we're here to have a good time and they're in a social environment.* [Corina, lifestyle activities coordinator]

Fostering Shared Reminiscence

Finally, the Tovertafel games provided opportunities for shared reminiscence. However, this reminiscence only occurred when the staff prompted the residents to share their stories in response to the games. By asking questions based on the game elements, the staff actively tried to prompt memories about the past. This included topics such as whether the residents used to keep animals in their garden, what they used to make for dinner, and what they typically did to celebrate birthdays—all of which were embodied within different games. This was seen as a particularly positive outcome of using the Tovertafel, as explained by 1 staff member:

> *Going back in time is good for them to feel good within themselves because it brings back memories. Like this morning, there were some songs that the residents remembered from their younger years. To me that's a good thing, reminiscing.* [Corina, lifestyle activities coordinator]

Prompting reminiscence enabled the residents to share their stories and learn about one another. In session 2, we observed that this reminiscence led to a protracted conversation in which a resident shared a story about a country property she helped renovate. The resident later retrieved a photo album from her room and began showing pictures of the renovation works to other residents. Interactions like these enabled the staff to engage in "biography work" [33], which involves learning about residents so that staff can address their needs using more culturally responsive practices. In this way, reminiscence appeared to be beneficial for the residents and the staff members attending each session.

Discussion

Principal Findings

Overview

This study aimed to understand how the care staff enable the Tovertafel in residential aged care and how this enablement contributes to benefits for residents. Our findings suggest that

staff facilitation was crucial for the effective use of the Tovertafel. This began with overcoming barriers to facilitating sessions, including the lack of a dedicated space for play and the need to encourage the residents to become involved. The staff then played a central role in supporting the residents through the activity, using creative techniques to guide the residents through the games and sustain engagement, while paying close attention to the safety of the residents. These actions helped residents gain meaningful benefits from the Tovertafel, which included fun physical activity, socializing with others, and opportunities for shared reminiscence.

Staff Enablement of the Tovertafel

Our findings highlight the central role the staff played in enabling the Tovertafel and the importance of creative care strategies in sustaining the participation of the residents. Previous work has argued that creativity can be required when providing enriching technology-mediated activities in care homes [34]. Our findings support this claim by showing how the care staff engaged in creative work during Tovertafel sessions. The Tovertafel provides a range of games, many of which are very simple. Although it may be hoped that the residents can play these games without staff oversight, our findings show that facilitation by the staff was needed to ensure that the residents understood the purpose of the activity, how to play the games, and how to interact with the system. In addition, the staff undertook a variety of creative actions to enhance the engagement of the residents *during* the sessions. The staff were conscious that the residents might choose to disengage from the Tovertafel, given the simplicity and repetitive nature of the games and because some of the residents had limited attention span. Creative actions around the selection and duration of the games helped to mitigate these risks and kept the residents' focus on the activity. These creative actions, in turn, were likely essential to fostering the benefits and outcomes observed in this study.

However, the involvement of the care staff was also needed to instigate the sessions. This work is arguably less desirable than tasks involving creative care. We observed how staff time was needed to set up the physical space for play—partly a result of where the Tovertafel was placed in the care home. The staff and the residents felt that the activity might be more popular if it were available to use in a dedicated space, such as an activities room. However, previous work has shown that when the Tovertafel was set up in such a space, it was still rarely used by the residents without prompting from caregivers [21]. This implies that facilitation may still be required *during* the use of the Tovertafel, irrespective of where it is located. We also found that staff time was needed to encourage the residents to attend the sessions, given residents' lack of experience with technology and uncertainty about what to do. These efforts can be viewed as a burden, but they also provided an opportunity for the staff to engage directly with the residents and understand their reasons for nonparticipation. The staff were then able to factor this into the running of the sessions, such as by starting with a simple game to help residents to become comfortable with the technology.

Finally, the care staff were involved in making sure that the residents remained safe during the activity. In residential aged care, many residents are frail or are living with cognitive impairment. This was true for many of the people who participated in the sessions we observed. The care staff ensured that these residents remained safe while using the Tovertafel. The staff believed that the Tovertafel involved some risks for the residents, particularly those who experience dizziness, and so they were vigilant about resident safety. Previous studies have highlighted the need for staff to ensure the safety of residents when using "risky" technologies such as exergames [35] or immersive VR [15,27]. Our study shows that the involvement of the staff was similarly essential to ensure that the residents remained safe when interacting with the Tovertafel.

Benefits of Using the Tovertafel

Our findings shed light on benefits arising from the staff-supported enablement of the Tovertafel. First, Tovertafel encouraged physical activity and provoked moments of fun and joy for the residents. It can be difficult to provide stimulating physical activities in residential aged care because of high rates of impairment among the residents [36]. Our observations suggest that the Tovertafel promotes gentle upper-body exercise but can require creative problem-solving and support from the staff to make the activities accessible. We observed this when the staff triggered interactions on behalf of the residents and through their efforts to make the game easier to play by using pieces of foam to extend the reach of the residents.

A second benefit was that the Tovertafel provided an opportunity for the residents to socialize with each other and with the care staff. Although care homes such as the one we studied frequently provide a range of lifestyle activities, opportunities for social interaction can remain scarce [37], contributing to experiences of loneliness [38]. To address these issues, previous work has explored the benefits of technologies that encourage "ludic engagement" through playful interactions between the residents [39,40]. The staff in our study felt that the Tovertafel was similarly beneficial because it brought residents together for playful, face-to-face interaction. This may be hard to achieve with technologies that are single-user focused, such as VR [15]. In addition, the staff noted that the Tovertafel demands cognitive engagement and encourages conversation. This was perceived to be more beneficial than passive activities, such as watching television. It was also perceived as beneficial for the residents who participated as "active audience members" [41], observing while others engaged with the Tovertafel.

A third benefit was that the Tovertafel enabled the staff to prompt reminiscence among the residents. When used effectively, reminiscence can be a positive activity for older people living in residential care [42] and can be supported using technology such as VR [43,44] and digital mapping systems [45]. However, these efforts are also typically single-user focused, and it has been found that while care home residents often engage in reminiscence with family and friends, they do so less frequently with other residents and the care staff [42]. This highlights a role for the Tovertafel in enhancing care: by drawing on elements of the games in a social setting, the staff were able to prompt reminiscence by encouraging residents to

share their life stories. Previous research has shown positive outcomes when care staff are involved in reminiscence because they can develop closer relationships with the residents and enhance their care work [46]. We saw this in our study when the staff used the Tovertafel to engage in "biography work," enabling them to learn new things about the residents [33]. Overall, these findings highlight how the Tovertafel can gently prompt reminiscence in ways that benefit both the residents and care staff. They also point to a positive feature of the Tovertafel games, whereby the open-ended design of most games allows for creative facilitation by the staff [34].

However, it is important to note that these benefits were contingent on the significant involvement of the care staff to enable the participation of the residents. On the basis of our findings, it is unlikely that similar outcomes will be achieved if the residents are not supported to use the Tovertafel. This may demand additional staff time in cases where the staff are not already rostered to support enrichment activities. The need for enablement by the staff, coupled with the high cost of the technology itself, should be a key consideration when deciding whether to invest in the Tovertafel. This study suggests that the Tovertafel can be an enriching small-group activity that can meet the needs of individual residents while affording opportunities for creative care work. However, as the staff had discovered at the home we studied, the Tovertafel should be adopted as part of a diverse activities program that includes large- and small-group activities; those that use digital technology; and those that encourage investment in physical infrastructure, such as gardening and interest-based hobbies [10,13].

Organizational Considerations for the Use of the Tovertafel

Our findings highlight several considerations that may inform decisions to implement the Tovertafel within residential aged care.

First, the Tovertafel is a high-cost investment that requires a significant amount of ongoing support to maintain use of the resource. The level of involvement from the staff required to effectively facilitate the Tovertafel is a potential barrier, especially in residential care homes where staff shortage is high, and priority is often given to meeting the personal care needs of the residents [2]. Aligning with previous work [21], our findings emphasize the competencies required by the staff to encourage the residents to use the Tovertafel, especially when those residents have cognitive impairment. This requires a team effort as the Tovertafel appears to work best with support from at least 1 staff member who can facilitate the engagement of the residents and maintain their attention.

Although training staff about the benefits and features of the Tovertafel is important [47], our findings demonstrate that training the staff *how* to creatively facilitate sessions may be even more valuable for maximizing its impact. This type of training is unlikely to be attained via reading manuals or resources and is better acquired through hands-on experience—as was the case with our participants. Training staff on good practices related to the Tovertafel could help with "onboarding" new staff to deliver the activity, given that staff turnover is a known barrier to the successful implementation of technology [16]. Alternatively, training could focus on developing the key competencies of the staff required for facilitation (particularly communication skills), allowing them to facilitate a range of activities [48].

In this study, we observed that facilitation skills were modeled to new staff by experienced staff and mentors. For instance, training typically involved a staff member demonstrating effective strategies while explaining the reasons for each approach aloud. However, this approach is likely to be an obstacle in residential aged care because of high staff turnover and limited staff-family training. Therefore, we recommend that staff receive general communication partner training, which can equip people with the skills required to respond effectively to the needs of the residents and to facilitate communication strategies [49]. Such training focuses on building interpersonal skills and fostering effective interactions, enabling staff to better engage with residents and enhance their facilitation capabilities.

Our study highlighted the need for an appropriate space to enable use of the Tovertafel. In the home we studied, the Tovertafel was situated in 2 specialized care areas: one for people with physical care needs and another for residents with severe cognitive impairment. However, in both locations, the Tovertafel was used in the main dining spaces, where the residents could not always see the projected images clearly. The need to set up the Tovertafel and pack it away meant it was not readily available for spontaneous activity or facilitation by family members and visitors. The residents and the staff felt that the system might be used more often if it were set up in a dedicated space, such as an activities room. This would enable the residents to access the resource with the staff as well as other available facilitators [21].

Third, appropriate scheduling of the Tovertafel needs to be considered to prevent disinterest among residents. According to the staff we interviewed, the Tovertafel had been dormant for some time before this study. This was because the residents had become uninterested in using it, leading to low attendance at the sessions. At the time of this study, staff were reintroducing the Tovertafel as a new activity to elicit interest. However, we observed that the Tovertafel was not well known among the residents compared to other activities. The Tovertafel was challenging to describe and required the staff to promote the benefits of the activity, relying on the residents' prior knowledge and interest in technology. Thus, the staff found it difficult to encourage residents to participate. This is challenging because the Tovertafel is an expensive technology and may be best deployed with larger numbers of residents so that it provides a return on investment.

Studies have reported that facilitators for promoting participation in technology-based activities can include communicating the benefits of use, building knowledge and confidence in using technology, and offering support during its use. In line with these findings, we offer some practical strategies for promoting interest in the Tovertafel: (1) communicating benefits; organizing informative sessions, where staff demonstrate the technology and its benefits, may increase residents' familiarity and engagement; (2) building knowledge and confidence in

using technology; sharing success stories and positive outcomes from previous sessions can serve as motivation for residents to participate; and (3) offering support; a buddy system could be established, pairing residents who are comfortable with technology with those who may be hesitant, fostering a supportive environment for participation. These strategies should be co-designed with residents and staff to ensure they are suitable for this context.

Limitations and Future Work

One limitation of this study is that we were only able to capture data about a handful of Tovertafel sessions, which occurred during a period of 4 weeks with a small number of residents. This may have constrained our observations on the breadth of strategies used by the staff. This limitation was mitigated through the use of diaries that were completed by the staff in additional sessions. Future studies can explore the impact of varying session lengths on the engagement of residents and strategies used by the staff to gain additional insights into effective facilitation techniques. Future research could also monitor the use of Tovertafel over the longer term to ascertain whether sustained engagement by both the staff and the residents occurs. Given the high cost of the device, ongoing use would be required for it to be cost-effective; otherwise, financial resources might be better spent on other beneficial activities and programs with higher engagement over the longer term.

Second, we focused on a single care home in Australia. However, gaining access to residential aged care for research is challenging, and studies are often based on a single site [8,10]. In addition, the Tovertafel is still not in widespread use, making it challenging to identify appropriate study sites to compare findings. Our findings have value in expanding the knowledge base about the Tovertafel and contribute to an improved understanding of the role that staff play in facilitating technologies that are hard for residents to use independently. For example, the benefits of enjoyment and physical activity from the Tovertafel align with a previous study conducted in the United Kingdom [21]. Nevertheless, further research should be conducted to identify context-dependent benefits and evaluate the transferability of our findings.

This study offers limited insight into the views of the residents. Many of the residents observed in our study did not have the cognitive capacity to consent to interviews. The residents who were interviewed had little to say about the Tovertafel, possibly because they were not fully aware of its potential features or because of their brief interaction with it. Future work should aim to provide a deeper understanding of the experiences of the residents. This information could then be used to inform best practices for care staff.

Conclusions

This study investigated the role of the staff in facilitating the effective use of the Tovertafel in 1 Australian residential aged care home. We found that creative strategies were needed to encourage the residents to use the Tovertafel and to support the participation of the residents in the activity. Beneficial outcomes included experiencing fun and joy, social interaction, and reminiscence. The staff proactively mitigated challenges in engagement, which included barriers to access and the adverse reactions that the residents may have to the experience. Aligning with previous research on the use of technology for enrichment in aged care [11,15,17], this study highlights the pivotal role of care staff in the adoption and use of digital technology, meaning that aged care providers need to account for staff involvement when deciding whether to adopt the Tovertafel.

Acknowledgments

This study was funded by the Australian government through a grant from the Australian Research Council awarded to JW (FT170100420) and by the University of Melbourne's Creativity and Wellbeing Research Institute. The authors would like to thank the participants for their willingness to support this study.

Authors' Contributions

JW conceived this study. JW, RMK, and AM designed the study procedures. RMK and AM collected the data. RMK led the data analysis and drafted the manuscript. RMK and AM revised the manuscript in response to reviewers' comments. RO, JAL, and JW edited each version of the manuscript and provided additional feedback.

Conflicts of Interest

None declared.

Abstract

Background: Older adults prefer to age in their home or community of choice, which could include naturally occurring retirement communities (NORCs). As a place with a high density of older adults, NORCs could be sites where technology is leveraged to support independence and aging in the right place. However, there is limited research on how technology adoption and use occur in NORCs in ways that support older adults.

Objective: This study aims to cocreate a research agenda on equity-informed technology considerations that help older adults live independently in NORCs.

Methods: This is a 2-phase sequential qualitative descriptive study of 5 community-based focus groups and an in-person World Café event. We use the focus group method to acquire data about older adults' experiences with and perceptions of using technology to support aging-in-place in NORC settings. This data informs the design and facilitation of deliberate dialogues at the World Café event. Three questions helped to guide the small group discussions. The World Café is a creative, collaborative, and conversation-generating method that aims to generate exchanges between people with different views on a particular topic.

Results: In total, 45 NORC residents participated in a focus group about their experience and use of technology. The data revealed 3 central categories that highlight the perception of the use of technology to support the independence of participants in their homes and communities, its challenges, and areas to consider when deploying technology for helping older adults age in place. The subsequent World Café event included 40 participants and a combination of NORC residents, service providers, researchers, technology innovators, and policy makers. Insights drawn from the focus groups and World Café informed a 10-question research agenda about equity-informed technology principles that span accessible support, accessible interfaces, affordable and equitable access, available digital literacy training, accessible data, and accessible partnerships.

Conclusions: Our study explores NORCs as potential environments for offering a transformative opportunity to address equity considerations for technology supporting aging in place. Our findings and research agenda highlight critical areas for consideration, including leveraging partnerships, integrating public and private technology ecosystems, and designing technology with older users that evolves with the population's needs. Notably, by embedding principles of equity, inclusivity, and user-centered design, the collective of developers, researchers, and service providers can ensure that emerging technology serves diverse aging populations equitably and effectively.

Introduction

Background

As the fastest-growing age demographic in Canada, older adults are expressing a strong desire to age in place [1]. This research defines an "older adult" as a person aged 65 years or older [2]. Aging in place refers to living safely, independently, and comfortably in one's home and community regardless of age, income, or ability level [3]. However, "aging in the right place" has been considered a more appropriate goal, given that place often depends on an older person's personal preference, circumstances, and care needs [4]. Advocates suggest expanding housing options for those unsuitable for long-term care by developing alternatives, such as senior apartments, assisted living residences, and so forth to create safer and more accessible living environments and support the desires of older adults to age in place [4,5]. Such settings could include adaptations made to the residential environments of older people for supporting their independence and improving their quality of life [6]. For example, incorporating digital technologies, such as movement sensors and medication dispensers, is increasingly used to mitigate declining cognitive and physical abilities [7].

One example of an alternative housing model is naturally occurring retirement communities (NORCs). Originally coined in 1986, NORCs are defined as a "housing development that is not planned or designed for older people, but which over time comes to house largely older people" [8]. The NORC Innovation Centre at University Health Network has expanded the conceptualization of NORCs to include that they may consist of communities designed to house many older adults but not purpose-built for this population in the way long-term care homes or retirement homes are [9]. NORCs can provide a model for healthy aging-in-place since many offer supportive service programs based on the needs of residents [8]. While the availability and capacity of government, social, and health service providers and policy makers can create opportunities for supportive programming [10], less is known about how technology is currently being leveraged within NORC environments to support the needs of residents. Technological advancements (eg, remote monitoring systems, wearable health devices, and mobile apps) have shown promise in supporting efforts to age in place [11,12]. For example, countries like the Netherlands and Spain have focused on technology to mitigate the need for additional care and promote independence and autonomy [13]. In particular, low-tech technologies are designed to be as simple as possible and can offer practical, low-cost, and accessible features [14]. Despite considerable public and private interest and investment in aging-in-place technology development and research [15,16], there has been limited adoption of advanced technologies and their impact on people and health care systems [17], including diverse older adults [18,19]. Gaps persist in accessing technology and enabling digital literacy to support aging in the place where one prefers [20].

Later in life, technology acceptance and adoption are often influenced by the digital divide, which is known as the gap between those who do and those who do not have access to or knowledge of how to use advanced forms of technology [21]. While many older adults actively use current technologies (eg, internet, tablets, and smartphones), the digital divide continues to be a barrier for older people with lower access (ie, devices, internet, financial, and digital literacy) [22]. The digital divide is even more pronounced in those who experience marginalization at the intersections of racial and ethnic identity and socioeconomic status [23-25]. Indeed, significant barriers to accessing or engaging with technologies for health-related needs could worsen racial and ethnic health disparities experienced by the aging population [25]. While technology can offer promising solutions to support older adults in Canada and other countries in aging in the right place [19], the digital divide, or the gap between those who do and those who do not have access to new digital and information technology, must be addressed [21].

Objective

With limited research on how technology adoption and use occur in NORCs in ways that support aging in place, this study aimed to cocreate a research agenda on equity-informed technology considerations that help older adults live independently in NORCs.

Methods

Study Design

This 2-phase sequential qualitative descriptive study [26] consisted of community-based in-person focus groups and an intersectoral World Café event. We used the focus group method to gather data about older adults' experiences with and perceptions of using technology to support aging-in-place in NORC settings. The focus group data, in combination with project team discussions, helped develop the overarching questions for the deliberate dialogues at the World Café event [27]. The World Café is a creative, collaborative, and conversation-generating method that aims to generate exchanges between people with different views on a particular topic [28].

Developed in 1995, the World Café is considered a participatory method [29] by shifting to a bottom-up approach by engaging as many different actors as possible in the data collection process [30]. The World Café was the preferred approach in this case, as it has been used extensively to convene community-dwelling older adults and intersectoral participants [31,32], including research prioritization activities [28]. The evidence also supports the World Café as a valuable tool for fostering productive conversations among individuals with lived experience. Finally, with World Cafés, a large and heterogeneous group of people

can be brought together in a systematic and organized manner [30].

We used the following 5 steps of the World Café method to guide our event planning: creating an informal environment, offering a warm welcome and overview from the host, engaging in 3 rounds of conversations among smaller groups of participants on 3 key questions (see), and a final round of sharing the conversation results with the broader group [29]. Typically, participants are encouraged to rotate tables intermittently and meet new people; however, since some participants had mobility differences, we adapted the format such that the "tabletop host" and a notetaker (ie, scribe) rotated tables instead. The following were the World Café questions:

1. What challenges do older adults living in naturally occurring retirement community (NORC) neighborhoods have that might be supported with technology to help them stay in their homes?
2. How might challenges with technology be the same or different for people who are newcomers, are from different cultural backgrounds, education, and income levels?
3. What other things should we think about when developing and using technological (or digital) tools that could help older people stay in their homes?

Sample and Recruitment

Focus Groups

We used purposeful sampling to identify and invite older adults living in urban NORCs in Toronto, Canada, to participate in a focus group. The inclusion criteria were community-dwelling older adults living in a NORC building. We identified NORCs from a publicly available list, including identified apartments, condos, co-operative housing, and social housing buildings within a bounded geographical area [33]. We used personal and professional networks to approach NORC buildings about the study. With agreement and support from the condo board or service providers at each location, we invited residents through word-of-mouth, circulating a recruitment flyer and using gatekeepers (ie, NORC residents or managers who brokered relationships between the researchers and the NORC building).

World Café

We also used purposeful sampling to invite interested focus group participants to the World Café. To ensure adequate representation of NORC residents in numbers, we used snowball sampling, encouraging focus group participants to share information about the World Café event with other residents. Because of the World Café's intersectoral nature, we invited representatives from housing, health and social care, academics and research, and government senior services to attend.

Data Collection

Focus Groups

Focus groups were held on-site in communal activity rooms within 5 different NORC buildings between April 2024 and June 2024. Each focus group involved a facilitator and a cofacilitator who supported the consent process, collected sociodemographic information, took field notes, and provided follow-up questions. The facilitator started each session by welcoming the participants, explaining the discussion's purpose, and inviting them to introduce themselves. With an interview guide, the facilitator guided the discussion to address the following three central questions: (1) tell me about your current care needs; (2) tell me how technology addresses or could address these needs; and (3) tell me about current challenges and benefits with technology. For the focus group participants, we broadly defined "technology" as the various tools, devices, and systems people use daily to facilitate tasks, improve efficiency, and enhance convenience, spanning assistive devices, telemedicine, health monitoring, information and communication technologies, and so forth [34]. The focus groups lasted approximately 45-70 minutes; the discussions were digitally audio-recorded and transcribed verbatim by one of the authors (MM).

World Café

The in-person, full-day World Café event occurred in June 2024 in a large workspace at a tertiary hospital in Toronto, Canada. Upon arrival, participants were asked to complete paperwork (eg, consent forms and demographic survey) and were seated at one of six tables. Each table had a tabletop host and a notetaker. The host and notetaker were assigned one of three questions and rotated at 3 intervals to allow all participants to build on the prior responses to the question and provide additional feedback. Upon completion of the third round, all participants were invited to participate in a group discussion, answering the final question: "What groups need to work together to ensure that new technologies that help older people stay in their homes treat everyone fairly?"

Data Analysis

Focus Groups

We used conventional content analysis to identify cross-cutting categories across the focus groups [35]. Conventional content analysis is most beneficial in the absence of existing research on the phenomenon. Therefore, it uses inductive logic, avoiding applying any predetermined categorical interpretation system [35]. Data analysis started with reading all transcripts, and 2 coders identified salient codes by highlighting exact words from the text to capture thoughts or concepts that appeared to describe an experience or perception of technology within the context of aging in place. Next, the first author created labels that reflected more than one concept, thereby sorting and merging codes into categories. Finally, the emergent categories were used to organize and group all the codes into meaningful clusters. For example, quotes like "[using technology to] connect with people near and far" and "interacted with all the kids and grandkids" were coded as "communication" and categorized under "Uses of technology."

World Café

For the World Café event, we used directed content analysis. This analysis seeks to validate or extend a theory or framework [35]. In this case, we applied the Social Ecological Model (SEM) [36] as an organizing framework to map the factors of technology use among NORC residents, considering the challenges and enablers. The SEM was selected because it

suggests that behavior is integrated into a dynamic network of intrapersonal characteristics, interpersonal processes, and institutional, community, and public policy factors [37]. Using the SEM also allows for identifying specific drivers of technology use or disuse among community members. Handwritten notes were transcribed and consolidated into a Microsoft Word document. In the coding process, we included examples for each of the factors. For instance, older adults' knowledge, attitudes, and behaviors are at the "individual" level of the SEM model. Similar to the focus group analysis, we reviewed the transcribed notes and coded the data using predetermined categories wherever possible. For example, better integrating "sensors in NORC buildings" and coordinating specialized technology training, as a NORC was coded according to the SEM's community level, acknowledges these factors as potential facilitators of aging-in-place. We also coded data that could not be categorized into one of the SEM factors, such as data related to technology devices and their features, design, and interface.

Ethical Considerations

This study was approved by the Mount Sinai Hospital Research Ethics Board (REB reference number 23‐0123-E). Study participants provided written informed consent before engaging in study activities. Three participants in each focus group received a $25 CAD (US $18) gift card as a draw, whereas World Café attendees were offered a $25 CAD (US $18) gift card with the option to decline. Participation was not anonymous due to the focus group and in-person event; however, participation was voluntary. The study findings will be disseminated through presentations at conferences and peer-reviewed publications using deidentified data.

Results

Characteristics of Participants

Focus Groups

In total, 45 people participated in a focus group, with each focus group having between 6 and 25 NORC residents. Of the demographic data we collected, most of the participants identified as female (n=30, 67%), between 70 and 89 years of age (n=33, 74%). The most identified ethnicities were White North American or European (n=29, 66%), Southeast Asian (n=3, 7%), and East Asian (n=3, 7%). Most participants indicated living alone (n=27, 60%), followed by living with a partner (n=14, 31%). The remaining participants lived with others (including family) or preferred to keep their information private. See Table 1 for Focus group participant characteristics.

Table . Focus group participant characteristics.

Characteristic	NORC[a] resident (n=45)
Gender, n (%)	
Women	30 (67)
Men	15 (33)
Age (y), n (%)	
60 - 69	10 (22)
70 - 79	21 (47)
80 - 89	12 (27)
90 - 99	1 (2)
Prefer not to answer	1 (2)
Ethnicity, n (%)	
White Northern American	19 (42)
White European	10 (22)
East Asian	3 (7)
Southeast Asian	3 (7)
Latino or Hispanic	2 (4)
Caribbean	1 (2)
Black African	1 (2)
Middle Eastern	1 (2)
Mixed heritage	1 (2)
Indigenous	1 (2)
Prefer not to answer	3 (7)

Employed for wages	1 (2)
Prefer not to answer	4 (9)

[a]NORC: naturally occurring retirement community.

World Café

A total of 40 people participated in the World Cafe. Of these, 18 identified themselves as NORC residents; the remaining individuals were system leaders, including service providers, decision-makers, researchers, technology entrepreneurs, innovators, and administrators. Of the NORC residents, most identified as female (n=14, 78%), were between the ages of 70

and 79 (n=9, 50%) years, lived alone (n=9, 50%) or with a partner or family (n=8, 44%), and most identified as White European or North American (n=12, 66%). For the system leaders (N=22), the average years of experience was 11 (SD 4.2) years, ranging from 2 to 17 years. Most participants held a graduate degree (n=15, 68%) and identified as female (n=18, 82%). See Table 2 for World Café participant characteristics.

Table . World Café participant characteristics.

Characteristics	Role	
	NORC[a] resident (n=18)	System leader (n=22)

Focus Group Findings

The focus group data revealed 3 central categories that highlight the use of technology to support participants' independence in their homes and communities, its challenges, and areas to consider when deploying technology to help older adults age in place (see Table 3).

Table . Focus group findings.

Category	Open codes	Direct quotes
Using technology	• Life is online • Connecting everyday • Finding information	• "When I leave my appointment everything comes online…medical appointments, email, the whole world." [FG 3] • "If there's something I don't understand how to do, I Google it and it sends me to YouTube where it explains how to do it. But it's so fast-paced that I have to keep rewinding it." [FG 2]
Expressing challenges using technology	• Goofing up the machine (cell phone) • Remembering passwords	• "I do not have a cell phone. I got rid of it a year and a half ago… I can goof the machine up very easy. I always seem to do that with cell phones." [FG 2] • "You have to remember to change your password every six months. We locked out and out because we forgot it." [FG 4]
Identifying technology considerations	• Needing to be taught • Thinking about income	• "My emails right now are coming into trash. And I'm at the point where I won't touch anything." [FG 2] • "We have been waiting for the whole building to be so-called fiber. Well, unfortunately, they have been trying to entice me to join by asking me to spend $90.00 a month. For a retiree, it's not really that simple" [FG 4]

Using Technology

Focus group participants described how they currently use technology to support their independence in their homes and communities. The types of use fell into categories of communication (eg, keeping in contact with family and friends), wellness and activity (eg, tracking upcoming appointments and online banking), information seeking (eg, accessing news, information, and current events), and for personal safety (eg, checking in on others). Some participants recognized the role of existing (eg, printer and video calling) and emerging technology (eg, ChatGPT and wearables) in adding value to their daily activities through access to information and connection to others.

> *I have a new iPhone. And I wanted to use it to make films. So I figured to make a film, you have to have a*

story to start. So, I asked ChatGPT what story I could use. And it gave me a story that was much, much too complicated. So you have a conversation [with ChatGPT] about simplifying it and making it something you can do in two-minute films? [FG 1]

Expressing Challenges Using Technology

Cross-cutting challenges expressed by the participants included the cost associated with technology, such as data or internet plans or fall alert technology; physical changes that make using technology more complex; and concerns related to fraud and data privacy. The latter was expressed in all focus groups, highlighting the vulnerability felt by older adults to financial scams. Another challenge often mentioned was the need for more digital skills or the inability to use technology, such as cell phones, optimally. This challenge was well aligned with the expectation that older adults must become familiar with current technology, as many tasks related to day-to-day societal functioning have become digitalized. This includes accessing lab results or medical records and online banking. Several participants also disclosed individual physical and sensory changes that made navigating technology interfaces more difficult for them:

I think some of us have physical problems. I have a lot of vision problems, so sometimes I can't even do anything at all because I can't see where the arrow is… the other thing is that I'm losing the ability to grasp with my hands, and that is horrible, but it, you know, it makes it difficult [FG 4]

Identifying Technology Considerations

Considering the challenges reported by our sample of NORC residents, many participants often suggested how to enhance their experience with technology. For example, they were intentional about receiving more technology support through education, training, and workshop-style learning. Our sample strongly desired someone to walk them through technology (eg, a digital navigator), especially when devices are seemingly not working and require troubleshooting advice. The desire for education also extended to avoiding cyber scams and using emerging technology, like ChatGPT. However, some participants resisted entirely internet-based systems and wondered about having either nontech or low-tech alternatives or technology that considered the unique needs of older adults, for example, a slower typing speed. Finally, participants also mentioned low-cost technology options aligned with their budgetary realities.

World Café Findings

According to the workshop participants, the SEM framework helped highlight challenges and facilitators of technology at the individual, interprofessional, community, organizational, policy, and technology device levels (see Table 4).

Table . Social Ecological Model framework.

Level	Challenge	Facilitator
Individual (ie, knowledge, attitudes, and behaviors)	• Fatigue with online appointments and expectation of online solutions (ie, "Zoom fatigue") • Hesitancy in asking for help with technology • Need for repeated exploration to acquire and develop digital literacy ("One-and-done doesn't work") • One's formal education does not equate to digital literacy	• Desire to have a "real" interaction • Identified characteristics of those who adapt to technology: healthier, open-minded, able to afford technology-related costs, willingness to learn and acknowledge technology shortcomings
Interpersonal (ie, family, friends, and social networks)	• Customer service supporting access to technology is not always respectful and informative • Technology cannot replace human connection	• Family available who can help facilitate set-up; family available to attend virtual meetings • Free of charge or nominal cost-required services equipped to help older people stay connected (eg, Geek Squad and Toronto Public Library)
Community (ie, relationships between organizations)	• Concerns about fraud and scams targeting older adults • Virtual programming may result in challenges (ie, long waitlists, lack of relief to caregivers, or social participation for users) • Ageism toward older people and technology, including them learning how to use technology	• Technology to see what resources or assets are available in the community (eg, grocery delivery and volunteer services) • Power in organizing a "collective idea or request" that supports collective learning and support for integrating technology solutions into living environments • Having people in your building or community who can help and whom you can trust • Building community and technology support ("economies of scale"), which may foster social engagement and participation • Leverage existing, trusted institutions like public libraries
Organizational (ie, organizations and social institutions)	• Customer service or technology support lacks the skills to communicate effectively with older adults (eg, they speak too loudly and give unclear instructions); people would rather live with the problem than deal with technology support	• Technology tutorials or programs (eg, how to sign a document) • Assistive devices in the home (eg, light sensors, passive sensors, and cane sensors) • Existing support system (eg, NORC[a] community coordinator) • Creation of a "digital navigator" to facilitate solution finding and increase user participation
Policy (ie, national, provincial, and local laws)	• Lack of policy requiring technology designed and customized to the needs of older users who consider sensory or cognitive differences • The government seemingly not engaged in supporting use of technology among older adults	• Affordable NORC phone, cell phone, and internet packages • Having technology partners represented at the policy level
Technology device (ie, features, interface, and design)	• Design does not meet the user needs, who may include older adults • Language translation, colors, and fonts need to be unavailable or easily customizable for everyone (eg, bigger font and different colors)	• Use of plain language or avoidance of acronyms • Considering aging-related changes in technology design (eg, mouse speed and color contrast for vision)

[a]NORC: naturally occurring retirement community.

The workshop discussions revealed that technology is not generally tailored to meet the needs of older adults, and the aging-oriented devices that do exist can be improved through more thoughtful and unique designs. According to the workshop participants, co-design is needed, where technology developers work with older adults from the onset of the conceptualization

and design process. Technology should not only be adapted for older adults but also specifically for different demographics and complex needs (eg, hearing impairment). An example of an improvement would be if device applications included multilingual options. Diverse groups of older adults must be consulted in technology development. Therefore, accessibility was frequently discussed, stressing the need for equity in technology design and access. In addition, the lack of affordability of technologies posed a significant barrier to accessibility, significantly disadvantaging lower-income groups. Participants suggested possible improvements, including reduced internet plans or group packages for NORCs.

The widespread adoption of technology to replace traditional services is becoming the default and can complicate many processes for older adults (eg, banking). Instead, there should continue to be a nononline option in addition to technology. The widespread use of technology is often blamed for reducing meaningful human interaction, which is concerning because people naturally seek social connection. Conversely, other participants voiced that information and communication technology allows connecting with others more easily, like family abroad, especially during scenarios of restricted movement, as in the case of the COVID-19 pandemic. Communication technologies (ie, Zoom [Zoom Communications] and Facetime [Apple Inc]) benefit virtual care, where technology can increase access to health care professionals and reduce wait times. Many participants noted they required more support for digital literacy to be comfortable navigating certain technologies, presenting a need for a tutor or someone available to answer technology-related questions, echoing insights from the focus groups.

It was suggested that aging communities, such as NORCs, should partner with programs or community agencies to support older adults in being technologically proficient. Technological literacy is critical in providing NORC residents with user confidence and helps to reduce anxiety around possible scams or security breaches. It was also suggested that instead of being compelled to accept the terms and conditions, users should be able to dictate the information that technology platforms share and with whom. Concurrently, technology could also provide a safety net at home. Many participants already appreciated using technology in remote monitoring and risk identification. Therefore, the ultimate goal to keep in mind when developing technology is how it can provide essential support in maintaining the independence of older adults to age in their preferred environment, which also evolves over an individual's lifetime.

Synthesizing insights drawn from the focus groups and World Café informed a research agenda (Table 5) of questions mapped to equity-informed technology principles.

Table . Research agenda.

Principles	Research question
Accessible support	• How can the NORC[a] environment support access and use of technology among older residents by leveraging existing and new partnerships (ie, City of Toronto, Toronto Public Library, and Connected Canadians)? • How do we leverage public (eg, Remote Care Monitoring) and private technology (eg, Apple Watch) ecosystems to support NORC residents to age in place? • What might be the most impactful ways in which technology could support community building and participation among NORC residents, local service providers, and agencies?
Accessible interfaces	• What are the technology design principles that consider the evolving needs of older adults, and how can these be integrated into current and future applications?
Affordable and equitable access	• How can technology developers be guided to commit to equity and adhere to it during the design and deployment phases of emerging technology? • How can government enact equitable and inclusive policies and funding to support the adoption of senior-friendly technology (ie, AgeTech)? Or policies to support alternatives to technology?
Available digital literacy training	• How do we create community-based co-located senior-friendly technology education and training opportunities to meet the diverse needs of aging adults? • How can education and training offerings be targeted to certain populations, for example, older adults who are new to Canada, those who are multilingual, are underhoused, and persons who have complex care needs?
Accessible data	• How do we measure the impact of technology on NORC residents, and find data-driven solutions?
Accessible partnerships	• How do we create an intersectoral and collaborative network of partners to support NORC residents to access and use technology, and who should be part of the network?

[a]NORC: naturally occurring retirement community.

Discussions

Principal Findings

We conducted a 2-phase sequential qualitative descriptive study of community-based focus groups and a World Café event to develop a research agenda on older adults' informed considerations for technology to support the aging-in-place of persons living in NORCs. We found several cross-cutting categories across study activities. Participants described using technology for various reasons, including connecting with others, wellness and activity, information seeking, and personal safety. However, our sample's technology usage was also impacted by barriers, such as limited access to (or outdated) devices, the cost associated with technology and its use (eg, internet), and a lack of available training or support to help fully use available technology or address low digital literacy within the context of age-related changes (ie, sensory, cognitive, and functional) that could hinder ease of adoption. The final set of 10 potential research questions underscores the importance of creating opportunities for age-friendly technology education, training, and equity in design, including design principles that reflect the evolving needs of older adults. Finally, the questions also emphasize the need to leverage intersectoral partnerships for supporting NORC residents who inhabit a unique living situation that enables the delivery of support within an existing community of persons aging in place. Therefore, accessing and using technology can serve as a mechanism for community building among NORCs and service providers.

Comparison With Prior Work

Our findings on the barriers to using technology among older NORC residents are similar to other research that found challenges across intrinsic (including individual physical and sensory changes) and extrinsic (including inexperience with technology and cost to access) factors [38]. However, some sociodemographic factors may significantly impact specific groups of older adults, like those on lower or fixed incomes, females, ethnic minority groups, those with lower education levels, and those who are older [39,40]. While our study did not examine the intersectional impact of race and sex on access to technology, other research suggests a significant disparity, with non-White older females having the least access to technology [40]. These findings speak to the ongoing digital

divide, referring to the gap between those with access to technology and those without. According to the literature, significant dimensions of the digital divide include digital literacy, affordability (costs), equity-denied group-related content and services (culturally appropriate content, activities, programs, and services), and access (infrastructure) [41].

NORCs, which include buildings or neighborhoods with a high density of older people, are home to highly diverse and socially and medically complex aging demographics [42,43]. Recent studies have found that NORC residents are older, more female, have lower incomes, live with more chronic conditions, and access home and primary care more often than non-NORC residents [43]. Together, these results suggest that there are more significant health needs than those of the general aging population; however, their communal living environment is particularly well-suited for leveraging. In this way, having a large concentration of older adults allows one to address technology needs in the same way health and social programming is delivered in NORCs [44], mainly through partnerships and collective efforts [45]. While we did not collect NORC participants' income levels, medical histories, or educational backgrounds, leveraging the collective power of a NORC environment to arrange, for example, technology training was mentioned during the World Café forum.

Despite the increased interest in equity-informed technology for older adults, limited research exists regarding NORC residents' adoption of technology that supports aging-in-place. Our findings align with previous interventional technology research (eg, sensory-based passive remote monitoring and smart speakers) implemented in NORC-like environments with lower-income and diverse older adults [46,47]. In these examples, access to a "cultural navigator" supported technology adoption through close relationships and information sessions [46]. However, without high-touch support for technology, its use among older residents may be limited to essential functions [47]. Similarly, NORC residents in another study expressed frustration and fear with using technology to access virtual programming during COVID-19 [48].

Strengths and Limitations

Our study uniquely positions NORCs and related collaborative relationships as one approach to consider when addressing the digital divide. Learnings from the NORC context could inform future digital health research, including design and implementation studies focusing more broadly on aging-in-place. The research agenda drawn from this study provides guiding questions that could help identify priority areas when considering equity-informed technology deployment and use in NORCs; they include viewing the opportunity to support aging in place with technology through various lenses. Finally, multiple data sources informed the agenda development, including a rapid review, a focus group, and a World Café. Despite these strengths, this study is not without limitations. For instance, the study data reflect a group of NORC residents and stakeholder participants. Our sample may not be generalized across other NORC settings, such as those in many rural and northern communities and across racial and ethnic minority and low-income older adults. In these settings, limited high-speed broadband internet continues to be problematic [49]. Likewise, since the target population in our study was NORC residents, certain strategies could be used to gather similar information from other population groups. As noted in the literature, partnering with community organizations, relevant clinicians, health service planners, and policy makers can leverage existing networks while establishing new relationships [28]. These networks not only serve to optimize participation among different community members, but they could also support ongoing initiatives catalyzed by the engagement. We also acknowledge that focus groups and World Café participants from NORCs had some degree of technology experience, which may indicate that we did not hear directly from those with minimal technical literacy. Therefore, a more targeted recruitment approach could have identified those significantly impacted by the digital divide. Another consideration is the potential influence that receiving the gift card could have had on participants' decisions regarding participation, for instance, being unduly incentivized to join the World Café. Finally, our final research agenda did not undergo a consensus exercise with our study participants. Future research could involve finalizing the agenda through a more iterative process, asking participants to rank questions on impact and importance.

Future Directions

Future research could tackle one or more of these questions by identifying conventional and nontraditional intersectoral partnerships between, for example, the public library system, academic health institutions, technology start-ups, the public education system, third-sector and charity organizations, and community-based service and housing providers. These new collaborative intersectoral models could help provide more accessible assistance to older adults within a communal environment who seek technology support [50]. Our study has begun to explore NORCs as unique environments that offer a transformative opportunity to address equity considerations in technology supporting aging in place.

Conclusions

Our findings and research agenda highlight critical areas for consideration, including leveraging partnerships, integrating public and private technology ecosystems, and designing technology with older users that evolves with the population's needs. Notably, by embedding principles of equity, inclusivity, and user-centered design, developers, researchers, and service providers can ensure that emerging technology serves diverse aging populations equitably and effectively.

Acknowledgments

The authors thank all the focus group and World Café participants for their invaluable contributions to the study. The Canadian Institutes of Health Research supported this work (award RN503880 - 498841).

Abstract

Background: Latino caregivers are at an increased risk of negative health outcomes due to the responsibilities of caring for someone with dementia. Although interventions exist to address caregiver burden, they often do not meet the cultural needs of Latino caregivers.

Objective: This study aimed to pilot test the cultural adaptation of the STAR-Caregivers Virtual Training and Follow-Up (STAR-VTF) intervention. The intervention is an evidence-based training program designed to teach family caregivers strategies to manage behavioral and psychological symptoms of dementia (BPSD). Our research team has conducted past studies to identify and perform culturally relevant adaptations to the training modules of STAR-VTF, and this study aimed to pilot these culturally adapted modules with a sample of Latino caregivers.

Methods: Data on feasibility, usability, and acceptability were collected from a pilot test in which Latino caregivers (n=16) used the training modules of the STAR-VTF intervention over a 7-week period. Participants completed usability surveys following the completion of each module, and acceptability was assessed through semistructured interviews (n=14) postintervention. Preliminary outcome measures were also collected, and a descriptive analysis was conducted. The primary outcomes were the Revised Memory and Behavior Problem Checklist (RMBPC) and the Preparedness for Caregiving Scale.

Results: The pilot study results suggest that it is feasible to deliver the culturally adapted STAR-VTF intervention to Latino caregivers, with 94% (15/16) of participants maintaining enrollment through intervention completion. The intervention's usability was found to be "good" based on an average System Usability Score of 76.7 out of 100 across all training modules. Caregivers were generally satisfied with the training modules. In addition, preliminary outcome results demonstrated a trend of decreased BPSD pre- versus postintervention (RMBPC subscale score: 28.24 to 21.34). Findings also demonstrated decreased caregiver reaction to BPSD pre- versus postintervention (RMBPC subscale score: 40.40 to 37.21) and increased caregiver preparedness based on pre- and postintervention (Preparedness Caregiving Scale score: 1.98 to 2.43).

Conclusions: The pilot study demonstrated that the culturally adapted STAR-VTF intervention is feasible and perceived as easy to use by a small sample of Latino caregivers. We aim to refine the cultural adaptations of the STAR-VTF intervention further based on feedback from study participants. Future studies are necessary to test the efficacy of the intervention and support the broad dissemination of the culturally adapted intervention.

Introduction

In the United States, Latino populations are disproportionately impacted by Alzheimer disease and related dementias (ADRD). Compared to White adults, Latinos are 1.5 times more likely to have ADRD [1]. By 2060, the number of Latinos with ADRD is expected to grow by 832%, which is the steepest increase in ADRD compared to any other racial or ethnic group, and projections show that by 2060, a total of 3.5 million Latinos will be living with dementia [2,3]. Latinos with dementia primarily rely on family members for their care due to the high cost of formal dementia care, legal status, barriers to accessing dementia care services, language preferences, and cultural preferences [4,5].

Latino caregivers comprise 21% of the estimated 40 million family caregivers in the United States [1]. Caregiving for a person living with dementia can be particularly challenging as ADRD can cause changes in personality and behavior, losses in judgment, orientation, and the ability to understand and communicate effectively [6]. Managing dementia symptoms requires intense supervision and physical support, and compared to other populations, Latino families provide more intense caregiving in terms of level of care and hours [1]. Caregiving for a person living with dementia also places Latino caregivers at increased risk of negative health implications, including high levels of stress, depression symptoms, less engagement in physical activity, sleeping problems, and social isolation [4,7]. Although evidence-based caregiver interventions exist to help address the negative impacts of caregiver burden, they often do not meet the unique cultural needs of Latino families [8]. Due to the negative health implications of dementia caregiving, it is crucial to support Latino caregivers through culturally adapted, evidence-based interventions.

STAR Caregivers (STAR-C) is an evidence-based systematic training program designed to teach family caregivers strategies to reduce behavioral distress and manage behavioral and psychological symptoms of dementia [8]. Caregivers are taught effective communication strategies, activator-behavior-consequence (ABC) behavioral problem-solving strategies, and how to identify and use pleasant activities to reduce behavioral disturbances [9]. STAR-C has been demonstrated to significantly reduce caregiver burden and depression and improve the quality of life of persons with ADRD [10]. Since the original randomized controlled trial of STAR-C in 2005 [11], the program has been adopted in various settings to meet caregivers' needs. One of the early adoptions of the STAR-C program in a real-world setting was conducted by the Oregon Department of Human Services-State Unit on Aging and Area Agencies of Aging, which served both rural and urban locations in Oregon [9,12]. In this implementation of STAR-C, the training was provided at home by trained professional health consultants to family caregivers. The program has since been adapted to teach caregivers the STAR-C lessons remotely. Tele-STAR, the telehealth-based adaptation of STAR-C, was created to increase access to anyone with a computer and internet connection and to reach rural populations [13]. Tele-STAR used videoconferencing to connect nurse consultants with family caregivers to guide them through the STAR-C lesson plans. The tele-STAR study found that with the transition from in-person training to remote, the family caregiver burden was reduced, and it retained good program and treatment fidelity to STAR-C [13]. Videoconferencing technology has also been used in the Illinois-based CRIS' Memory Care Program, an adapted STAR-C intervention developed by CRIS Healthy Aging, a nonprofit organization in East Central Illinois that serves older adults primarily in rural communities and of lower income [14]. The latest adaptation of STAR-C in a clinical setting has been STAR-C Virtual Training and Follow-up (STAR-VTF), which was tested at Kaiser Permanente Washington [15]. STAR-VTF is a 6-to-8-week program comprised of six training modules that caregivers complete asynchronously. It also includes 30-minute weekly check-ins with a program coach. Support from program coaches is provided as needed for up to 6 months via secure messaging in the Kaiser Permanente Washington patient portal.

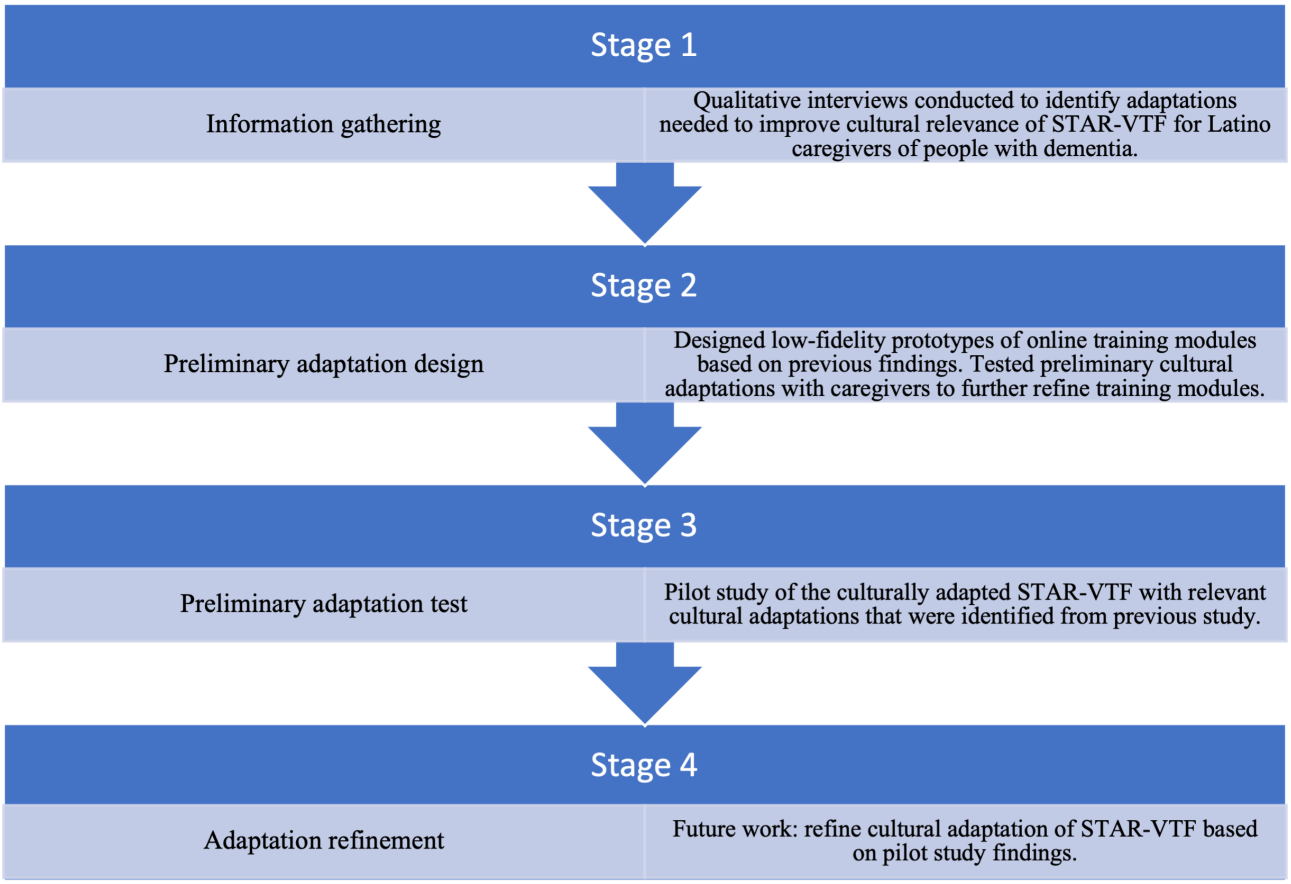
Although STAR-C has been adapted in a variety of ways to expand access to caregivers, it has yet to be tested in large populations of Latino caregivers. Recently, our research team adapted STAR-VTF to improve its cultural relevance and linguistic appropriateness for Latino caregivers [8,15]. We conducted an 8-week pilot study of the culturally adapted training modules from the STAR-VTF intervention. This study reports findings on the feasibility, usability, acceptability, and preliminary outcomes of the pilot study with Latino caregivers. The findings will help improve future iterations of STAR-VTF for Latino caregivers, and more generally, advance our understanding of modifying evidence-based interventions to better serve Latino caregivers of persons with dementia.

Methods

Design

The framework for the cultural adaptation of evidence-based interventions developed by Barrera and Castro [16] guided the methods of this study. The framework includes the following stages in culturally adapting an evidence-based intervention: (1) gathering information to identify ideas about needed adaptations, (2) conducting preliminary adaptations based on these ideas, (3) conducting pilot studies of the preliminary adaptations, and (4) refining adaptations based on results from pilot studies. Our research team has completed the first two stages [8,15]. This study presents findings in the stage 3 process of pilot-testing cultural adaptations (Figure 1).

Figure 1. STAR-VTF cultural adaptation process. STAR-VTF: STAR-Caregivers Virtual Training and Follow-Up.



This single-arm pilot study tested the feasibility, usability, and acceptability of the culturally adapted STAR-VTF training modules. We also trialed data collection procedures and collected preliminary data on persons living with dementia and caregiver outcomes pre- and postintervention to obtain descriptive estimates. Quantitative and qualitative methods were used in this pre- and posttest study.

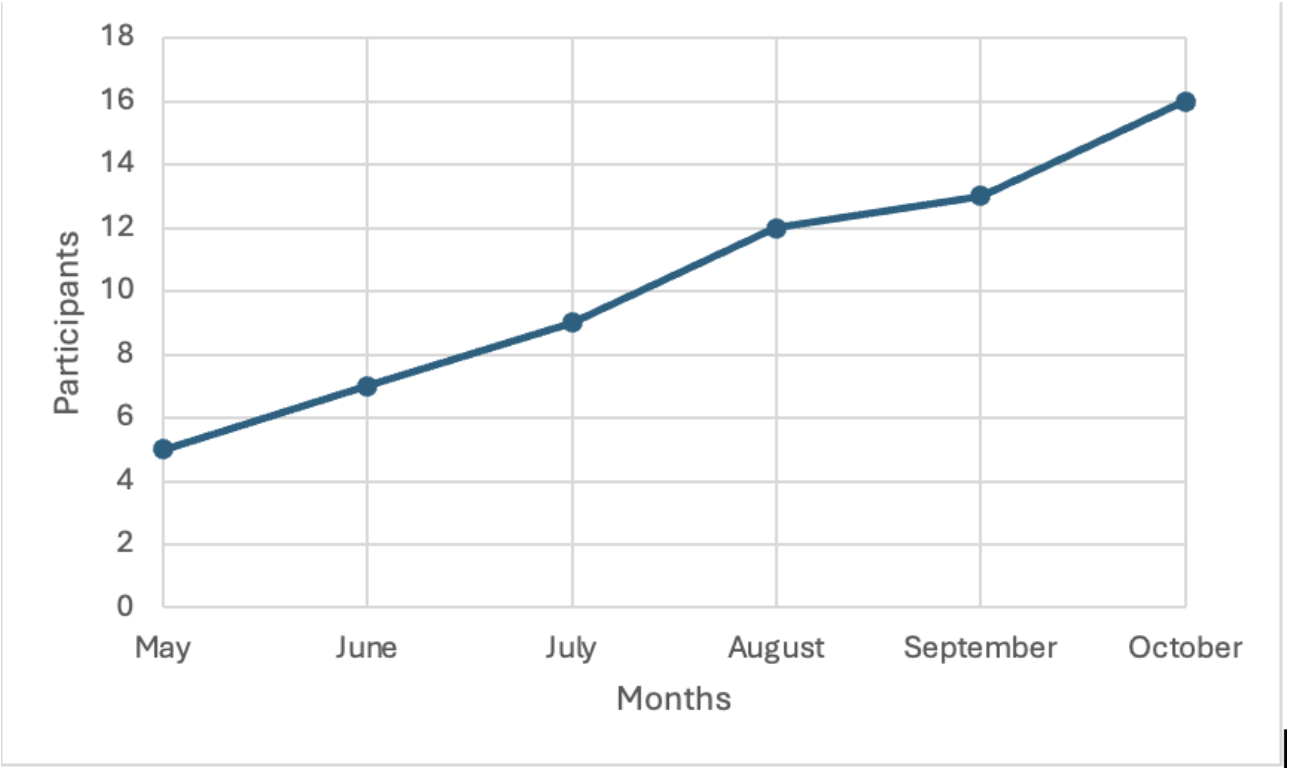
Ethical Considerations

The Advarra Institutional Review Board approved this study (Protocol: National Institute on Aging - FY20_Pilot10_Ramirez). If interested, participants were screened for eligibility, and digital or written informed consent was obtained. Consent was collected from participants via a consent form that was provided in English and Spanish, depending on their preference. Translation of the consent form was done by a certified Spanish translator. Participants were provided a US $40 gift card for their participation. All study data were deidentified and stored on secure, password-protected cloud storage.

Participant Recruitment

Potential study participants (ie, Latino caregivers) were identified using the UW Medicine electronic health record, UW Alzheimer's Disease Research Center Registry, Alzheimer's Prevention Registry maintained by the Banner Alzheimer's Institute, and through the distribution of recruitment flyers through professional networks. Potential study participants were contacted by bilingual staff via phone or email to explain the study and answer their questions about study participation. To be eligible to participate, participants had to identify as Hispanic or Latino, be 18 years of age or older, be taking care of a family member or friend with dementia, live with or within 5 miles of the person living with dementia, spend at least 8 hours a week with them, and indicate that the person they care for is experiencing at least three symptoms related to dementia occurring at least three times in the past week. Figure 2 provides additional information on the number of participants who were enrolled over time for this pilot study.

Figure 2. Enrollment timeline.



Intervention: Culturally Adapted STAR-VTF Training Modules

While the full STAR-VTF intervention consists of weekly training modules and weekly 30-minute phone check-ins with a coach [15], this study only pilot-tested the culturally adapted modules. The adaptations used in this pilot study were based on findings from previous qualitative studies [8,15]. These studies interviewed Latino caregivers of persons with dementia, as well as health care and social service providers of older Latinos, to improve the cultural relevance of STAR-VTF. Based on the findings of prior studies, adaptations included revising language viewed as problematic, expanding content to enhance understanding of dementia, and adding cultural examples that reflect family involvement in caring for relatives with dementia and multigenerational living [8,15]. Additional refinements made to the STAR-VTF training modules, after testing preliminary modules with Latino caregivers, included adding empathetic messaging that highlights the importance of viewing the world from the perspective of the person living with dementia, incorporating additional problem-solving examples to demonstrate diverse challenges, and emphasizing caregiver self-care, to ensure caregiver's mental and emotional health is prioritized [8].

For 7 weeks, caregivers completed training modules asynchronously. They accessed the modules via email or SMS text message. This pilot study was focused on testing the content of the training modules; therefore, caregivers did not receive the coaching component of the STAR-VTF intervention. There were 7 training modules in total. Caregivers were instructed to complete one module per week. The content of the modules is described in Textbox 1.

Textbox 1. Content of the STAR-Caregivers Virtual Training and Follow-Up training modules.

Module 1

- Provides an understanding and overview of dementia.

Module 2

- Introduces caregivers to the behavioral treatment of dementia, realistic expectations, and effective communication.

Module 3

- Covers the antecedents, behaviors, consequences (ABC) approach to problem-solving, including rationale and development of an ABC plan. Hypothetical scenarios of how caregivers successfully used the ABC problem-solving to address behaviors (eg, wandering) are included.

Module 4

- Instructs caregivers to review the ABC plan and revise it as needed.

Module 5

- Covers pleasant events and managing negative thinking.

Module 6

- Instructs caregivers to review the ABC plan, pleasant activities schedule, and to revise as needed.

Module 7

- Covers coping with caregiving and maintaining the use of caregiving strategies.

The length of the training modules ranged between 7 and 16 minutes each. The modules used text, pictures, and illustrations with a voiceover presentation. Caregivers received the training modules in their preferred language (English or Spanish). They also received a printed or electronic workbook to accompany the lessons (the format depended on their preference). The workbook contained additional educational materials, as well as worksheets for caregivers to write down their ABC plans. Intervention materials, including training modules, voiceovers for modules, and workbooks, were translated into Spanish by a certified Spanish translator. Study participants were enrolled in the study for approximately 8 weeks.

Measures

Feasibility

We assessed feasibility based on National Institutes of Health guidance on appropriate feasibility measures for pilot studies [17]. Feasibility measures included details of the success of procedures to recruit eligible participants, retention, and intervention completion.

Usability

To assess usability, we collected data on the System Usability Scale [18] via a REDCap (Research Electronic Data Capture; Vanderbilt University) survey each time a caregiver completed a training module. With the System Usability Scale survey, caregivers rated how easy the training modules were to use. Each item was rated on a 5-point scale ranging from 0=strongly disagree to 5=strongly agree.

Acceptability

Assessment of acceptability was accomplished through semistructured qualitative interviews with participants after they completed 7 weeks of the STAR-VTF training modules. Interview questions explored the participant's experience with the program and solicited feedback on recommendations for further improving the program.

Person Living With Dementia and Caregiver Outcomes

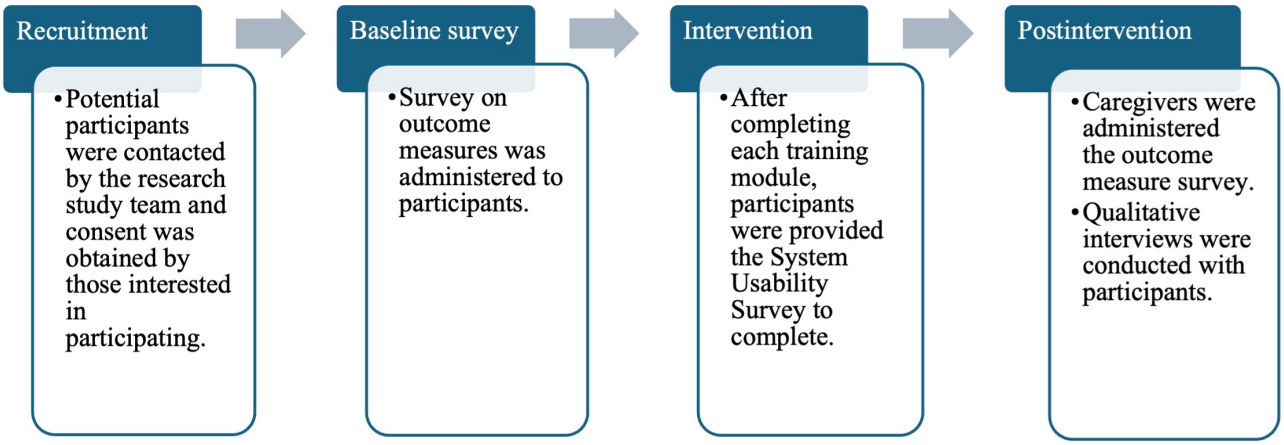
The primary outcomes were the Revised Memory and Behavior Problem Checklist (RMBPC) [19,20] and the Preparedness for Caregiving Scale [21]. The outcomes were collected at baseline and 8 weeks postenrollment via a REDCap survey. For the RMBPC, caregivers rated memory, depression, and disruptive behavior problems in the person living with dementia. The instrument contains 24 items (7 memory-related, 8 depressive, and 9 disruptive) that assess problem behaviors and are rated for frequency of occurrence during the past week and caregiver reaction, which refers to the extent to which caregivers were distressed by the problem behaviors. The Preparedness for Caregiving Scale was used for caregivers to rate how prepared they are for various aspects of caregiving. The instrument contains 8 items that ask caregivers how well prepared they believe they are to provide physical care and emotional support, deal with the stress of caregiving, and set up in-home support services. Each item is rated on a 5-point scale ranging from 0=not at all prepared to 5=very well prepared.

Data Collection

Timeline of Data Collection

The data for this study were collected pre- and postintervention and throughout the intervention period. For reference to the data collection timeline, see Figure 3.

Figure 3. Time of data collection.



Quantitative Data Collection

We collected outcomes data on the RMBPC, Preparedness for Caregiving Scale, and System Usability Scale via REDCap surveys in Spanish and English. The Spanish versions of these scales have been validated and found reliable [20,22,23]. Research assistants on the project delivered a link to the surveys via email or SMS text message to caregivers. These surveys were provided to participants at baseline and postcompletion of the training modules.

Qualitative Data Collection

All participants who reached the end of the study were invited to participate in a semistructured interview conducted in Spanish or English. All interviews with participants were conducted over the phone with bilingual research team members (CG and LZ). The interview guide included questions about their opinions on the program training components, suggestions for improving course content and design, and the quality of the Spanish translation of training modules (Multimedia Appendix 1). The average length of interviews was approximately 30 minutes. Interviews with participants were audio recorded, and the transcription of the interviews was done by a professional transcription service.

Quantitative Data Analysis

We analyzed quantitative data using descriptive statistics. Based on National Institutes of Health guidance, we did not conduct outcome analysis for effect size estimates since an effect size estimated from a pilot study is inherently unstable and would not provide helpful estimation for power calculations [17].

In the descriptive analysis, we only included study participants who completed the outcome assessments at baseline and 8 weeks. If study participants had missing values in their responses (either because they skipped an item or responded with “Don’t Know/Not Applicable”), then we imputed their missing values. The missing data were imputed by taking the highest possible score that participants could obtain if they answered all items and then multiplying that score by the quotient of the participant’s actual score divided by the highest possible score they could have received from the items they answered.

Qualitative Data Analysis

To analyze qualitative data, we used qualitative analysis methods outlined by Miles et al [24]. Interview transcripts were coded and analyzed in their original language (English or Spanish) using Dedoose (version 9.2.007), a cloud app for managing, analyzing, and presenting qualitative and mixed method research data. First, bilingual team members (MAM, CG, and MR) read the transcripts and wrote brief notes of what was in the data. Next, the first (MAM) and second (CG) authors independently coded transcripts using inductive codes. They convened weekly with the senior author (MR) to discuss the application of codes, refine the codebook consisting of inductive codes, and reach a consensus on coding discrepancies. After coding three transcripts, the codebook was comprehensive, and a few additional codes needed to be added. The first author individually coded the remaining transcripts, with guidance from the senior author as needed. Descriptive and in vivo codes were used in the coding process.

The first author identified preliminary themes based on the inductive codes by collating and reviewing excerpts of each code. During this process, relationships among codes and relationships within and among themes were assessed. A collection of relevant excerpts for each theme was pulled from the data while reviewing coded excerpts. Recommended areas of assessment in the third stage of Barrera and Castro’s [16] framework on cultural adaptations of evidence-based interventions, such as satisfaction with intervention elements and suggestions for improvement, were used to help guide theme creation. The preliminary themes were iteratively refined with assistance from the second and third authors (CG and MR) to ensure that subthemes within the themes were relevant to the parent theme and that the final themes were distinguishable.

Results

Participant Characteristics

In total, 16 participants enrolled in the pilot study of the culturally adapted STAR-VTF training modules. Table 1 provides demographic characteristics of the study participants. Demographic characteristics were collected at baseline.

Table . Participant characteristics.

Characteristics	Study participants (n=16)
Age, mean (SD)	51.2 (13.2)
Gender, n (%)	
Man	4 (25)
Woman	12 (75)
Hispanic or Latino origin, n (%)	
Mexican, Mexican American, Chicano or Chicana	10 (62)
Puerto Rican	1 (6)
Other	5 (31)

[a]GED: General Educational Development.

[b]Column percent may not add up to 100% because categories are not mutually exclusive.

Feasibility

We achieved satisfactory feasibility based on recruitment, retention, and intervention completion measures. We recruited 16 study participants. The initial recruitment goal was to recruit 20 participants, and we reached 80% of our goal (16/20). Of the participants recruited, 94% (15/16) of participants were retained for all 8 weeks of the pilot study. The proportion of participants who completed all 7 training modules and participated in all study procedures (qualitative exit interviews, pre- and postoutcome assessments, and weekly usability surveys) was 75% (12/16).

Usability

Usability was assessed for each training module. Average scores and SDs for each module were calculated (Table 2). The average System Usability Score across all 7 modules is 76.7 out of 100, which is considered "good" usability, indicating that caregivers perceive the STAR-VTF training modules as easy to use [24,25].

Table . System Usability Scores.

Week	System Usability Score, mean (SD)
1 (n=13)	77.8 (10.8)
2 (n=12)	77.7 (12.9)
3 (n=10)	74.6 (19.2)
4 (n=13)	73.7 (16.3)
5 (n=12)	75.8 (14.3)
6 (n=9)	79.2 (14.5)
7 (n=11)	78.0 (13.7)

Acceptability

The results of the semistructured interviews provided information about the cultural adaptations of the STAR-VTF training modules. The qualitative results also provide a further understanding of what changes are needed to revise the cultural adaptations further.

Theme 1: Latino Caregivers Were Satisfied With the STAR-C Intervention Content and Design Elements of the Training Modules and Accompanying Workbook

Overview

Latino caregivers were generally satisfied with the content covered in the STAR-C intervention, including components on dementia education, ABC problem-solving, and caregiver support strategies. They also expressed satisfaction with the design of the training modules and the accompanying workbook.

Dementia Education Component

Latino caregivers found the dementia education information beneficial in understanding their relatives' dementia condition and how it can progress. There was also a consensus among most caregivers that they liked the empathetic messaging embedded within the dementia education component. Caregivers felt that it was helpful to be reminded that their family member has a condition of the brain and that some of the things their family member says or does are not on purpose, and to be encouraged to have patience and understanding. A caregiver providing care to their father said the following about the messages reminding caregivers to be empathetic:

> *And I felt like it was an important reminder because I guess just like with anything else, even as a parent of young children, I get caught up in the day-to-day and the getting things done, and there's deadlines, and there's work and home life and all sorts of things. And so it is nice to have that reminder that it's not just ... not to take things personally and not to be so quick to react. But just a gentle reminder, there may be another reason why my dad is saying something or not doing something. And yeah, just not to take it personally, so that was a helpful reminder.* [ID 11]

ABC Problem-Solving Component

Many Latino caregivers expressed that the ABC problem-solving strategy of the training was helpful and found the examples used to demonstrate how to implement the strategy to be relatable to their own caregiving experience. One of the training modules demonstrated a hypothetical caregiver using the ABC problem-solving strategy to address a person living with dementia wandering. When asked about their thoughts on this example, one of the caregivers stated:

> *So I thought it was very relatable. And then sort of just kind of showcasing what happened, I think, made it relatable in the sense that you can sort of put yourself in that situation. And then for me, I was like, "Okay, yeah. I could see how this happens, and then what can you do to utilize those ABCs to then basically make it useful for your own personal experience in a similar situation."* [ID 14]

Latino caregivers also shared how the ABC problem-solving strategy was successful in helping them manage their relative's behavioral and psychological symptoms of dementia and provided anecdotes of their experience applying the ABC problem-solving strategy. For example, one of the caregivers described how they used the strategy to address their mother's experience of washing dishes. The caregiver said:

> *So my mom would get really upset and would complain of dizziness around the same time every day. And I thought that was odd. And then when I was doing this and I took the ABC, I realized that the*

reason my mom was getting upset was because she would wash the dishes at the same time every day at, and sometimes I would go by and tell her, "Oh, turn the water higher," or, "Oh, put more soap." And I think me trying to coach her was upsetting her because it made her feel like she didn't know what she was doing. So she would go, and she would say she's dizzy, and she would start to cry. And then because I noticed the timing, what happened before and after, I stopped doing that. I just let her wash the dishes. [ID 27]

Caregiver Support Strategies Component

Latino caregivers overwhelmingly related to the caregiver support strategies, encouraging caregivers to practice self-care. Caregivers expressed the importance of caring for themselves to care for others. They also acknowledged the importance of taking time for themselves. For example, a Spanish-speaking caregiver providing care to his wife explained the reasons why it was important for caregivers to prioritize their own self-care.

It's good that you made us see what we need, also we need to take care of ourselves to be able to provide care. In my case, my wife needed me to be good so I could take care of her well. One needs to sleep well and eat well to give the best help to the sick. (translated quote) [ID 06]

Design of Training Modules and Accompanying Workbook

Latino caregivers were satisfied with the design of the training modules and the accompanying workbook. Some caregivers said they liked the pacing of the training modules and the images used. One caregiver shared the following about the training modules:

I like the pace of it, and I liked the way that it was almost like going through a PowerPoint presentation. I liked that there were slides that kind of bulleted the info that I could either read along to or that it included images that were ... let me see. Images of people of color and not just an elderly White family. [ID 11]

Some of the caregivers described the workbook as a helpful resource to refer to information and strategies that had been covered in the training modules. For example, one of the caregivers planned to continue referencing the workbook after the research study ended. They stated:

So I think for me it's [the workbook] going to be a helpful guide now that I don't have access to the videos to go through it and remind me of things and I can share it with my other family members who are also trying to help with caring with my mom. So I feel like the workbook is kind of the legacy of those classes. [ID 27]

Theme 2: Suggestions for Improving Program Content and Making Training More Engaging

Overview

Although Latino caregivers were generally satisfied with the training modules, some caregivers shared suggestions that they felt would enhance the intervention. The areas for improvement that Latino caregivers suggested are the inclusion of information on additional resources and improving the interactivity of training modules to make videos more engaging.

Including Information on Additional Resources

Latino caregivers expressed wanting additional information on resources outside of the program that they can access to help support people living with dementia. Although some resources were presented in the training modules, caregivers shared they would like more resources on dementia care and community organizations serving people living with dementia and their families. For example, one caregiver shared:

Maybe what might be helpful is if you had ... now this would be just ... I guess you'd have to make it unique for every state, but maybe give them some resources of where they might be able to reach out to. There's different Medicaid programs that might be eligible for. There might be local dementia associations that they could contact, those types of things, right? So resources that people might be able to reach out to, especially ones that offer services in Spanish. [ID 17]

Improve Interactivity to Make Training Modules More Engaging

Some Latino caregivers provided suggestions for improving the interactivity of training modules to make learning program content more engaging. A suggestion to improve the interactivity of program content was to include knowledge checks or short quizzes in which caregivers can test their knowledge of the material covered. As one caregiver shared:

Having something that's a little more interactive where it's not just a video, but almost like a course where you watch a video and then ... having both options like an actual paper workbook or having the option to select multiple choice or just to keep the viewer engaged in the video. So even if it's like, "Here's a summary. Which of these apply?" Select A, B, C, or D, all of the above, or something like that, just so that it really just keeps the viewer engaged. [ID 11]

Latino caregivers also felt there were areas in which the training modules could be improved visually to make them more engaging. A suggestion that was shared by caregivers was to include video reenactments to demonstrate how strategies learned can be used in real-world situations. For example, one caregiver shared they liked the ABC strategy examples in the training module but mentioned that if they were recreated in a video depicting a role-play of the scenario, it would be more engaging. As the caregiver explains:

> *I feel like an actual video example of the dialogue would go a lot further than the pictures with the text-next-to-them pictures. If I remember correctly, that's what they were. They were pictures of the humans, of the woman and the person, her caregiver, and then there was just dialogue text next to them. It made sense. It just seems very dry. It seemed very dry. And I didn't really feel like I was paying attention as much as I should have in those moments.* [ID 24]

Some caregivers also suggested the importance of including testimonials from fellow caregivers of patients with dementia about their experiences with caregiving and how they applied the STAR-VTF training. One caregiver shared how incorporating caregiver testimonials can help demonstrate how to implement strategies covered in the training, such as the importance of caregiver self-care:

> *I think probably maybe interviewing some caregivers and having them share their journey from not knowing what's going on with your mother ... she's crazy ... to understanding what's happening and the realization that it is an illness and examples of how they continued on with taking care of their health. It's very stressful. It's very stressful. I mean, it creates a physical response in your own body. And so I think it's just the affirmation from others that what they've done to manage their own time and their own feelings and examples like that and reassuring us that it's okay. It's okay to leave them and do something fun like go to a movie with your husband instead of feeling guilty about it.* [ID 28]

Theme 3: Caregivers Share Dementia Care Information With Others and Suggest Outreach Strategies

Overview

Latino caregivers shared how they have increased awareness of dementia care strategies by sharing the information they learned in the training modules with relatives. Caregivers generally shared program content by word of mouth or by sharing the link to the training modules that were provided to them. Latino caregivers suggested additional avenues to spread awareness of the STAR-VTF program, such as working with community partners and using social media.

Sharing Information With Relatives

Multiple Latino caregivers shared that they valued the information provided in the training and that they shared this information with family members who assist in the care of the person living with dementia and with family members who are in a similar caregiving role. For example, one caregiver said:

> *So I shared the videos with a group chat for the seven-week period. It was a group chat of my caregivers for my Nana, including myself. So it's going to be my sisters, my two sisters, my two cousins, my father, my uncle, and my aunt. And all of us took part in that group chat, and I shared it with them every time I got a new video because I felt like it was something that we could all benefit from. We all share the same struggle right now. And even though we're not in the same place, as far as mentally, taking care of my grandmother, this is a step to getting us all on the same page. And it seemed like the right thing to do to share the information that I was getting and make sure that my family understood why I was doing what I was doing.* [ID 24]

Community Outreach Strategies

To further improve the STAR-VTF program outreach, some caregivers shared that it is important to partner with trusted Latino community organizations, community health workers, religious centers, and caregiving organizations. As one caregiver explains, to reach Latino communities, it is important to consider partners who have established trust in the community to establish the credibility of the program. The caregiver said:

> *So often Latinos they feel more trusted with people that they know, so family and friends or church or organizations. So if you can tap into those kind of communities to share it, I think, will probably be your best bet in getting the word out. Even my mom, she's very hesitant to go to the doctor. I have to take her because she grew up in a generation where they kind of mistrust doctors, but they trust their sisters or cousins. And if they come at them with information, they're more apt to use it than if it comes from a really formal setting. So to say that word of mouth, that community-centered family groups, community groups, churches, any kind of groups that have a good connection to the Latino community, I think they're more apt to use the information you're providing.* [ID 27]

Some caregivers also suggested advertising the intervention in medical facilities and partnering with health professionals. As one Latino caregiver shared:

> *Working with the community health workers, they can put it out (information on intervention) or maybe have something in the rural area at the doctors. I know they have a lot of doctors. So if it's just one doctor's office, if you have some handout or a little small TV screen that's on loop playing some of that information, it would be good.* [ID 09]

Some Latino caregivers also shared the importance of the STAR-VTF program building a digital presence by posting the training modules on social media, such as Facebook, to reach Latino populations. Caregivers believed delivering the STAR-VTF program through these platforms would increase the reach of the program. For example, one caregiver shared:

> *You can put them (training videos) on Facebook, on social media, and then when you're on social media, you could pop up and ... because you could be on social media on the weekends, and then your study would pop up, or your videos would pop up on the weekends and ... because people are always on social media day, morning, night, weekends, holidays, so if*

you had your content available on social media, then they would be able to view it. [ID 08]

Preliminary Outcomes

The average RMBPC score for a person living with dementia behavior problems changed from 28.24 (SD 18.31) at baseline to 21.34 (SD 16.76) postintervention, indicating a decreased frequency of behavior problems (Table 3). The average RMBPC score for the caregiver's reaction to behavior problems changed from 40.40 (SD 16.68) at baseline to 37.21 (SD 14.60) postintervention, indicating decreased caregiver reaction to behavior problems. Furthermore, the average Preparedness for Caregiving Scale score changed from 1.98 (SD 0.33) at baseline to 2.43 (SD 0.32) postintervention, indicating increased preparedness for caregiving. The findings show a trend toward decreased behavior problems in the person living with dementia, decreased caregiver reaction to behavior problems, and increased caregiver preparedness after versus before the intervention.

Table . Results for RMBPC[a] and Preparedness for Caregiving Scale at weeks 0 and 8.

	Week 0, mean (SD)	Week 8, mean (SD)
RMBPC		
Problem Frequency, overall (n=14)	28.24 (18.31)	21.34 (16.76)
Problem Frequency, memory subscale (n=14)	7.70 (5.35)	4.98 (3.63)
Problem Frequency, disruption subscale (n=14)	10.24 (7.95)	6.39 (6.20)
Problem Frequency, depression subscale (n=14)	10.73 (10.36)	9.23 (10.35)
Caregiver Reaction, overall (n=13)	40.40 (16.68)	37.21 (14.60)
Caregiver Reaction, memory subscale (n=13)	19.21 (5.70)	18.64 (6.52)
Caregiver Reaction, disruption subscale (n=13)	9.35 (6.54)	8.14 (5.27)
Caregiver Reaction, depression subscale (n=13)	11.85 (7.52)	10.43 (5.88)
Preparedness for Caregiving Scale Score (n=14)	1.98 (0.33)	2.43 (0.32)

[a]RMBPC: Revised Memory and Behavior Problem Checklist.

Discussion

Principal Results

This study aimed to pilot-test the culturally adapted STAR-VTF training modules among Latino caregivers of people living with dementia. Delivering the culturally adapted STAR-VTF training modules to Latino caregivers was feasible, with a high proportion of participants completing the study procedures. The training modules were also found to be easy for Latino caregivers to use based on the high average of System Usability Scale scores across modules.

The qualitative analysis of interviews with Latino caregivers who completed the 8-week program revealed their high satisfaction and acceptability with the training modules and components on dementia education, ABC problem solving, and caregiver support strategies. The study also identified areas for improvement in the training modules, such as providing caregivers with information on additional resources and enhancing the engagement of training videos. The study also provided valuable insights into expanding the intervention's reach, including through word of mouth, partnerships with community organizations, and social media. These findings will significantly contribute to the refinement of the culturally adapted STAR-VTF training modules for Latino caregivers. The culturally adapted STAR-VTF intervention was also found to have positive changes in the outcomes of behavioral problems among people living with dementia and caregiver preparedness among the small sample of Latino caregiver participants. Further research is needed to examine the efficacy of the culturally adapted STAR-VTF intervention.

Comparison With Prior Work

This is the first pilot study that tests a cultural adaptation of the STAR-VTF evidence-based intervention for Latino caregivers. Our findings on the feasibility of the culturally adapted STAR-VTF intervention are comparable to other interventions for dementia caregivers delivered digitally, which were also feasible [26,27]. However, unlike these studies, this study consists exclusively of Latino participants, which provides further information on the feasibility of digital interventions for Latino caregivers. Preliminary findings of positive mental health outcomes and improvements in caregiver preparedness are similar to findings from a systematic review of literature on internet-based interventions aimed at supporting family caregivers of people living with dementia [28]. The studies presented in the systematic review of digital dementia caregiving interventions reported reductions in caregiver stress, depression, and strain and improvements in self-efficacy [28]. However, conclusions from these studies and this pilot study should be made with caution due to study design limitations, as these studies consist of quasi-experimental, small randomized controlled trials, pre-post studies, and feasibility studies.

Our findings on acceptability and Latino caregivers' satisfaction with training components in this pilot study were consistent with the identified needs and wants of caregivers who participated in a qualitative study to test low-fidelity versions of the culturally adapted training modules [8]. In the pilot study, Latino caregivers expressed how the module on dementia education was especially beneficial to their understanding of dementia; this finding aligned with caregivers' perspectives of wanting more dementia education in the previous study of

low-fidelity training modules [8]. The desire to learn about ADRD from Latino caregivers of people living with dementia is also consistent with findings from a qualitative study that examined barriers and facilitators to increasing engagement of Hispanics or Latinos in clinical trials on ADRD [29]. In this study, a majority of caregivers expressed an eagerness to receive information about ADRD, including details on the different types of ADRD, specific risk factors for Latino communities, and hereditary characteristics [29].

Another aspect of the training modules that resonated with Latino caregivers, which was highlighted in our previous qualitative study, was the inclusion of reminders for caregivers to be empathetic toward people living with dementia. Our findings on caregiver satisfaction with the caregiver support strategy component are also similar to findings from our previous study in which caregivers highlighted the importance of self-care [8]. The need for information on self-care by Latino caregivers was also highlighted in a qualitative study that explored the needs of Latino caregivers of relatives with early-onset Alzheimer disease [30]. This study found that among their 27 participants, they overwhelmingly expressed the need for additional information concerning self-care, especially mental health care strategies and stress management [28]. Caregivers' high satisfaction with the training components piloted in this study suggests that we effectively integrated feedback from Latino caregivers to meet their needs in the training content.

Regarding our findings on areas of improvement, Latino caregivers' needs for additional dementia care–related resources are consistent with findings from a mixed methods study on the health information–seeking behavior of Latino caregivers of people living with dementia. The study on health-seeking behaviors found that Latino caregivers desire to seek various types of dementia information, including the availability of community resources, health care services, and treatment [31]. Caregivers in this pilot study also suggested improving training videos by making them more engaging with video reenactments of caregiving scenarios, knowledge checks, and caregiver testimonials. This aligns with findings from our prior qualitative study wherein Latino caregivers who viewed the low-fidelity modules expressed the idea of having real people in the videos to depict caregiver scenario examples [8]. Multiple studies have found that using video vignettes in the form of telenovelas and Spanish soap operas is an acceptable and effective method of delivering health information to Latino caregivers [32-34]. Furthermore, a study that evaluated the acceptability of a web-based course for caregivers of older adults found that caregivers liked having postmodule quizzes, and they also had a caregiver suggest the use of caregiver testimonials in course modules [35]. Our findings show that these preferences in web-based training are also warranted among a sample of Latino caregivers.

Limitations

Although preliminary outcomes were positive, this study had several limitations. First, due to the small budget, we were not able to pilot-test the full STAR-VTF intervention, which consists of weekly training modules and weekly 30-minute phone check-ins with a coach. It is during these check-ins that coaches review caregivers' ABC plans. Future pilot studies will include the coaching component, which will also ensure that the ABC plans are being developed appropriately. Second, general limitations of pilot studies apply, such as the inability to determine efficacy and estimate effect sizes for power calculations of a larger-scale study [17]. The target sample size of 20 for this pilot study was determined based on logistical constraints, as it was the maximum feasible within the available budget and study timeline. Third, the pre-poststudy design is subject to limitations due to the lack of a comparison group, which relies on conclusions formed from the temporal relationship of the measurements to the intervention. This type of study does not allow researchers to control for other changes that could have occurred around the same time as the intervention that could have influenced outcome results [36]. A limitation of the qualitative portion of this study is that caregivers had trouble recalling details about earlier training modules. A caregiver shared that since it had been over a month since they viewed the first couple of training modules, it was difficult to remember some of the specific details of the content covered. When conducting interviews with participants, the research assistants (CG and LZ) would sometimes need to remind caregivers about earlier training modules. The time gap between viewing the earlier training modules and being interviewed can result in recall bias, and participants may have omitted important details regarding their experience. Another limitation of this study is that 10 of the 14 interviews were conducted by the same research assistant who recorded the voiceover for the modules. If participants recognized that it was the same person, it may have led to social desirability bias, as participants may have provided answers that would be viewed favorably by the research assistant.

Conclusions

This pilot study found the culturally adapted STAR-VTF intervention to have high levels of feasibility, usability, and acceptability. In general, caregivers found the training modules beneficial and relatable and were highly satisfied with the cultural adaptations to the STAR-VTF intervention. The feedback from the qualitative interviews with Latino caregivers will help inform decisions during the fourth stage (Adaptation refinement) of the Barrera and Castro [16] framework on the cultural adaptation of evidence-based interventions to refine future iterations and meet Latino caregiver needs. Although future research is still necessary to test the efficacy of the culturally adapted STAR-VTF program, this pilot study provided valuable information about the feasibility, usability, and caregiver experiences with the intervention. This study also contributes to the broader knowledge of modifying evidence-based interventions to better serve Latino caregivers of persons with dementia.

Abstract

Background: Despite the increasing interventions to support family caregivers of people with dementia, service planning and delivery is still not effective.

Objective: Our study aimed to develop a digitally-supported needs assessment tool for family caregivers of people with dementia that is feasible, time-efficient, understood by users, and can be self-completed in the primary care setting.

Methods: The development of the unmet needs assessment tool was part of a cluster-randomized controlled trial examining the effectiveness of a digitally supported care management programme to reduce unmet needs of family caregivers of people with dementia (GAIN [Gesund Angehörige Pflegen]) and was conducted in 3 phases. Using an iterative participatory approach with informal caregivers, health care professionals including general practitioners, neurologists, psychologists, psychiatrists, nurses, and Alzheimer Society representatives, we developed a digital self-completion unmet needs assessment tool focusing on informal caregivers' biopsychosocial health und quality of life in connection to their caregiver responsibilities. Data were collected through group discussions, written feedback, protocols, think-aloud protocols, and interviews, and analyzed thematically.

Results: Data from 27 caregivers, including caregivers of people with dementia (n=18), health care professionals (n=7), and Alzheimer Society representatives (n=2) were collected. Thematic analysis identified 2 main themes: content of the assessment tool and usability and handling of the digital tablet-based assessment tool. The feedback provided by the stakeholders led to new aspects and changes to make the tool comprehensive, easy to read, and easy to handle. The overall mean completion time was reduced from the initial 37 minutes to 18 minutes, which renders the assessment tool fit to be self-completed in waiting rooms of primary care practices or other settings.

Conclusions: The input of the 3 stakeholder groups has supported the development of the assessment tool ensuring that all aspects considered important were covered and understood and the completion of the assessment procedure was time-efficient and practically feasible. Further validation of the assessment tool will be performed with the data generated as part of the GAIN trial.

Introduction

The World Health Organization (WHO) estimates 55 million people are living with dementia worldwide, with an increase to 78 million by 2030 [1]. In Germany, approximately two-thirds of the 1.8 million people with dementia are cared for at home by an informal caregiver, most often a relative [2]. Numerous studies have shown that caring for a relative with dementia is associated with a multitude of time- and resource-intensive challenges [3-5]. Emotional stress, social isolation, depression,

and financial burden are among the negative consequences that dementia family caregivers have reported [6-10]. To alleviate these consequences, interventions for the reduction of caregivers' burden have been developed [11-14], such as telephone-based as well as multicomponent psychosocial and individualized support programs [11,13]. With the growing consensus that caregiver support is an integral part of the care of patients with dementia, there was also an increase in interventions to support informal caregivers [12]. However, each caregiver's situation is different and requires an individual set of interventions. Individualized interventions are still underused in care practice as they require time and dementia-specific expertise that is often lacking in primary care. A systematic and comprehensive yet individualised unmet needs assessment tool would be useful for health care professionals (HCPs) to better plan services and interventions in clinical settings as it would flag areas where the individual caregiver needs support.

In a mixed methods study, Stirling et al [15] used Bradshaw taxonomy of need [16] to explore the relationship between different types of caregiver service need. Bradshaw and Care [16] defined categories of need as measures of professionally identified carer burden (normative need), service use (expressed need), carer's stated need (felt need) and the comparison of groups using services with groups who do not (comparative need). It is argued that no single measure of the above needs is likely to capture all carer's unmet needs. In the light of person-centred care, the normative need has been increasingly challenged as paternalistic and inappropriate [15,17].

Therefore, a focus on caregivers' stated need (felt need) as well as service use (expressed need) would be an appropriate starting point to consider for an unmet needs assessment tool. An individualized, digitally supported self-assessment instrument can aid in the efficient identification of health and support areas that should be addressed from the perspective of the informal caregivers. This allows collaborative intervention planning and reduces the risk of a paternalistic doctor-patient relationship [18]. If a digital system is to truly ensure collaborative service planning, the digital assessments instrument must be developed with the participation of the users themselves.

The direct input of family caregivers and other stakeholders into the content, structure, and handling of the digital assessment system provides crucial feedback regarding its content validity as well as comprehensiveness and technical usability. Through a greater level of involvement of stakeholders, health care services can be improved and be more applicable in real-world clinical settings and facilitate implementation [19]. A systematic review of instruments used to assess the needs of family dementia caregivers identified 36 instruments that were described in detail or in part in the 70 publications included [20]. The authors reported that only one instrument was partially validated to assess the needs of family dementia caregivers, namely, the Carer's Needs Assessment for Dementia (CNA-D), a semistructured interview not intended for clinical use with a completion time of about an hour. For conceptual clarity, researchers recommended establishing a theoretical model or framework to organize the diverse needs of family dementia caregivers [21]. In addition, researchers argue that a focus on the detection of changes in family caregivers' needs throughout disease progression is important [20,22].

Therefore, the aim of this study was to develop a digital unmet needs assessment tool that can be used in primary care settings. We conducted the study in collaboration with informal and formal caregivers and other stakeholders. Our objectives were to (1) create a user-friendly and family dementia caregiver specific digitally supported assessment tool, (2) develop an assessment process that is understandable and comprehensive yet time-efficient, and (3) create an assessment tool that can be used at multiple locations such as general practitioners' (GPs) offices and memory clinic waiting rooms.

Methods

Overview

The development of the assessment tool was in preparation of the upcoming randomized controlled intervention trial examining the effectiveness of a digitally supported care management intervention for family caregivers (German title: Gesund Angehörige Pflegen [GAIN]). The trial was supported by the Federal Joint Committee (G-BA [Gemeinsamer Bundesausschuss/Innovationsausschuss]). The funding code (FKZ) is 01VSF18030).

Participants

We involved individuals from 3 stakeholder groups, namely, family dementia caregivers, health care professionals (general practitioners, neurologists, psychiatrists, psychologists, and nurses), and Alzheimer Society representatives. We approached HCPs of a medical university and memory clinic staff, as well as Alzheimer Society representatives, and asked for their feedback (phase 1). Family dementia caregivers who were visiting a memory clinic with their relative or friend with dementia were asked whether they would like to provide feedback on the paper-based version of the assessment instrument regarding the content, clarity, and comprehensiveness (phase 2) as well as the usability of the digital version of the assessment tool as a self-completion assessment instrument on a PC tablet (phase 3). No further demographic data were collected.

Procedure

We used an iterative user-centered participatory approach with 3 phases. Previously used questionnaires [20,23,24] assessing unmet needs and care interventions from previous dementia care management studies [4,25-31] in Germany were used as starting point.

Phase 1

In phase 1, the authors developed a list of previously used questionnaires assessing unmet needs in family dementia caregivers as well as a list of available care interventions offered in Germany. The selection of questionnaires was based on a comprehensive review of the literature covering the databases OVID, MEDLINE, and PsycInfo searching for unmet needs, caregiver needs assessments methods and family dementia caregivers. With respect to available care interventions, we used work from previous dementia care management studies

management studies [4,25-31] offering a list of interventions to family dementia caregivers in Germany. We used Germany-based intervention studies as these are health care system specific. Criteria for the inclusion of questionnaires were the content they covered (eg, quality of life, psychosocial factors, and health-related domains), their previous use in research and interventions, and their completion time. We also considered questionnaires based on either their recommendation by the EU Joint Programme in Neurodegenerative Research (JPND) Working Group on Longitudinal Cohorts or common use in larger German trials such as IDemUck [32], DelpHi-MV (Dementia: life- and person-centered help in Mecklenburg-Western Pomerania) [26,28], intersec-CM [33,34], or DemNet-D [35,36]. These questionnaires are validated and allowed comparison with German and international studies. The authors then further discussed these selections in meetings, compared 5 separate versions of a possible unmet needs assessment instrument and checked whether items would cover interventions offered as part of the dementia care management conducted in previous primary care studies [4,26,28,37,38]. With this approach, we wanted to ensure that the operationalization of problem-centered needs were connected to available services within the German health care system and could therefore be addressed in this framework accordingly.

The authors selected different assessment versions aiming to cover all biopsychosocial aspects and compared different scales for caregiver burden. The need items were then compared and matched with the list of informal caregiver interventions from previous studies—these were marked according to a match or no match. This allowed the calculation of percentages of “items covered” from the dementia caregiver intervention list for each version of questionnaires. The five versions of combinations of questionnaires were checked by 3 authors and researchers for plausibility. The results of this item-intervention matching process were used to identify which versions covered most unmet needs with matched possible interventions. These are shown in Table 1.

Table . Proportion of match with family dementia caregiver interventions.

Versions and interventions		Match, %

[a]FIMA: Questionnaire for the Use of Medical and Non-Medical Services in Old Age [39].

[b]URN: Caregiver unmet resource needs scale [40].

[c]EQ-5D-5L: Health-related quality of life [41].

[d]ZBI-7: Zarit Burden Interview [42,43].

[e]LSNS-6: Lubben Social Network Scale [44,45].

[f]BIZA-D: The Berlin inventory of the burden on relatives - dementia – Module 3,5,and 6 [46].

[g]CANE: Camberwell Assessment of Need for the Elderly [47,48].

[h]DQoL-OC: The Dementia Quality of Life Scale for Older Family Carers [49].

[i]HABC: Healthy Aging Brain Care Monitor—Caregiver Version [50].

Versions 3 and 4 covered most items, whereas versions 1, 2, and 5 covered less than 50% of the dementia-specific items. The two versions covering most unmet needs were then presented and discussed at an advisory board meeting with input from HCPs (eg, neurologists, psychiatrists, psychologists, and nurses) and Alzheimer Society representatives. Meeting minutes were recorded of all points raised and discussed. This input was used to select the final version of the assessment tool.

Phase 2

In phase 2, the chosen assessment version covering most unmet needs was tested in a memory clinic. A tablet computer was deemed most appropriate to serve as digital device due to its size, weight, flexibility, and ease of handling. Based on a previous study on the use of a tablet-based digital expert system [26,28,30], we had taken several decisions on the hardware basis of our system before the participatory part of our study started. The content and usability aspects, however, were developed together with future users. The authors approached family dementia caregivers in a memory clinic to provide feedback and suggestions on a paper-based version of the assessment tool. The changes were primarily focused on the Camberwell Assessment of Need for the Elderly (CANE) questionnaire, as well as the demographic and informal caregiver-specific questions, as these were items that could still be adapted. Family caregivers who were interested in

contributing were given a short version comprising 7 questions of the CANE questionnaire. The researcher noted the caregivers' comments and thoughts in a think-aloud protocol. Together with a researcher, they were asked to read the questions and share their thoughts with respect to each question and their understanding thereof. The focus was on comprehension, words and sentence structure, answer options, descriptions, and additional comments. In the second round, both informal caregivers and health care professionals were approached to provide feedback on the whole printed version of the assessment instrument. Those who agreed to provide feedback were asked to mock-complete the assessment tool and write down their notes and questions. In this round, informal caregivers and HCPs were asked to measure the time needed to complete the assessment procedure. We provided written questions such as "Are the questions clear and easy to understand?"; "Where did you encounter problems when completing the assessment?"; "Did you have issues understanding the questions?"; and "Are there questions or areas that should be in the assessment set but are currently missing?" Based on the feedback received, the first draft of the assessment set was modified resulting in a second draft. When adapting the first draft, our focus was on the assessment procedure being clear and easy to understand for family caregivers in terms of the way questions are phrased. Based on the feedback we received, several parts of the assessment set were adapted and duplicates were removed by the authors resulting in the final draft.

Phase 3

In phase 3, a digitalized tablet-based version of the final version of the assessment tool was tested for its technical usability. In this phase, we asked both informal caregivers and HCPs to test the digital assessment tool with a focus on the handling of the tablet. Data was collected through interviews and think-aloud protocols. Family caregivers in a memory clinic were asked to complete the digital assessment tool in the waiting room and share their thoughts and comments with a study nurse or researcher who protocolled the comments. Similarly, HCPs of a medical university and a memory clinic were asked to complete the digital assessment procedure and write down feedback on the handling and any possible bugs or problems they noticed while testing the digital system.

Analysis

All data collected through written feedback, protocols, think-aloud protocols, and interviews were analyzed thematically following the steps by Braun and Clarke [51]. The six phases involved were (1) familiarizing ourselves with the data, (2) generating initial codes, (3) constructing themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report [51].

Ethical Considerations

The study is conducted in accordance with the criteria (valid at present) of the Declaration of Helsinki, the ICH-guidelines for Good Clinical Practice, the Memorandum for Safeguarding Good Scientific Practice (German Research Foundation), and the International Ethical Guidelines for Biomedical Research Involving Human Subjects. Ethical approval has been obtained from the Ethical Committee of the University Medicine Greifswald (BB120/2019) and the Ethical Committee of the University Medicine Rostock (A2020/0013). The trial is registered at ClinicalTrials.gov (NCT04037501).

Results

Results of the development of the assessment tool of the 3 phases are divided in the subsections presented below. The process of phases 2 and 3 was iterative comprising several rounds through which we collected feedback, made changes based on feedback received and then moved to the next round of collecting feedback.

Participants

A total of 27 family caregivers of people with dementia (n=18), HCPs (n=7), and Alzheimer Society representatives (n=2) participated. Among the HCPs were general practitioners, neurologists, psychologists, psychiatrists, and nurses. The mean age of the 27 family caregivers was 57 (SD 13.78; range 35‐88) years and 9 (50%) were women. The HCPs' and representatives' mean age was 41 (SD 8.05; range 28‐50) and 6 out of 9 (67%) were women. As this was a participatory approach, no further demographic data were collected.

Phase 1: Structure and Content of the Assessment Tool

After the input from the advisory board including neurologists, psychiatrists, psychologists, nurses, and Alzheimer Society representatives, the final structure of the assessment instrument was selected. It was the one with the highest percentage of matches between problem-centered needs and the associated interventions (69/72, 96%; version 3; see Table 1).

The unmet needs assessment tool comprised several validated questionnaires with a total of 57 questions examining a person's self-reported demographic information, use of medical and nonmedical services, unmet needs (CANE), health-related quality of life (EQ-5D-5L), caregiver burden (Zarit Burden Interview [ZBI]), and social support (Lubben Social Network Scale [LSNS]). It can be completed using a digital version or a paper-based version. In total, the assessment set covers 51 health- and support-related aspects.

Domains covered by the unmet needs assessment tool are the following: (1) health and care, (2) employment, (3) information and knowledge, (4) emotional support, (5) social support, and (6) caregiver burden.

The structure of the unmet needs assessment tool can be seen in Table 2.

Table . Structure of the unmet needs assessment tool.

Instrument	Domain

[c]LSNS: Lubben Social Network Scale.

[d]ZBI: Zarit Burden Interview.

The number of unmet needs addressed the participants' medical needs, home care needs, psychosocial needs, and needs connected to the caregiver role. This needs assessment instrument included selected parts of the CANE [47].

Health-related quality of life was assessed using the EQ-5D-5L [41]. This instrument comprises 5 dimensions: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression. Each dimension has 5 levels varying from no problems to extreme problems. Each level corresponds to a 1-digit number that expresses the level selected for that dimension ranging from 1 to 5 with higher numbers indicating more severe problems. The digits for the 5 dimensions can be converted into an overall index by an not publicly accessible algorithm. The index describes the participant's health-related quality of life. It also contains a vertical visual analogue scale (EQ VAS), with endpoints that are labelled "Best imaginable health state" and "Worst imaginable health state." The VAS reflects the patient's own judgement and can be used as a quantitative measure of health outcome.

Social support was assessed using LSNS-6 [44,45]. This scale is a self-report measure of social engagement including contact to and interaction with family and friends on a 6-item scale. Total scores range from 0 to 30 with an equally weighted sum of the 6 items. The family and friends subscales include questions regarding the number of friends and family one has regular contact with as well as their availability for help and support in private matters. High scores indicate strong social networks.

Informal caregiver burden was assessed using the 7-item version of the Zarit-Burden Interview (ZBI-7). The short version ZBI is a caregiver self-report measure to examine burden, which is associated with functional and behavioral impairments in the social, psychological and physiological context, and home care situation [42,43]. It contains 7 items using a 5-point scale. Response options range from 0 (Never) to 4 (Nearly to Always). Total scores range from 0 indicating no burden to 28 indicating severe burden.

Phases 2 and 3: Feedback Received on the Assessment Tool

Themes

A total of two main themes were derived from the analysis: (1) content of the assessment instrument and (2) digital tablet usability for the assessment tool. Each theme had further subthemes and subtheme categories and were divided in either informal caregivers or HCPs and Alzheimer Society representatives as these groups had different areas they paid special attention to. Almost all subthemes had 1 to 3 subtheme categories, see Table 3.

Table . Themes, subthemes, and subtheme categories.

Theme and subtheme	Subtheme category
1. Content of the assessment procedure	—[a]
Informal caregivers	—
1.1 Comprehension	• 1.1.1 Simplification of questions • 1.1.2 Simplification of answer options • 1.1.3 Separate questions for caregiver health and caregiver care responsibilities in relation to the person with dementia
1.2 Assessment structure	• 1.2.1 No multiple questions in a table • 1.2.2 Questions whether help is needed in a specific domain for clear identification of unmet needs
1.3 Reduction of completion time	• 1.3.1 Fatigue
1.4 Areas important to caregivers	—
Health care professionals	
1.1 Assessment structure	• 1.1.1 Order of instruments • 1.1.2 Focus on caregivers' health and care responsibilities
1.2 Reduction of completion time	—
2. Digital tablet usability of the assessment tool	—
Informal caregivers	
2.1 Simple layout	• 2.1.1 Large font and buttons
2.2 Handling	• 2.2.1 Manual answer selection
Health care professionals	
2.1 Simple layout	• 2.1.1 One question per screen • 2.1.2 Option to go back and forth within the assessment procedure • 2.1.3 Progression bar
2.2 Handling	—

[a]Not applicable.

Content of the Assessment Instrument

Regarding the assessment's content, informal caregivers provided information on 4 subthemes regarding the comprehension, assessment structure, reduction of completion time, and areas important to them.

Comprehension (Informal Caregiver Perspective)

Regarding the clarity of the assessment procedure to them, caregivers commented on the simplification of questions and answer options. Instead of "This is an unmet need" or "This is a need met" (as suggested in the CANE) they preferred to answer "Yes" or "No," for instance. They also commented on being sometimes confused whether a question was referring to themselves or to the person diagnosed with dementia indicating that questions had to be framed specifically.

Assessment Structure

Regarding the assessment's structure, informal caregivers commented that multiple questions in a table format were confusing. In addition, some commented that they would like to self-identify the areas where they needed help rather than having professionals assume that they needed help or support in an area, which was incorporated into the assessment procedure by first asking whether there is a problem in a specific area and secondly asking whether the respondent receives enough help with respect to this problem. A yes or no response to these questions would then indicate the presence or absence of an unmet need.

HCPs and Alzheimer Society representatives considered the order of instruments within the assessment procedure and argued that the instrument covering most unmet needs (CANE) should be moved to the front to prevent that important health care domains received less attention due to fatigue. They also reported that the informal caregivers' own health as well as factors influencing their health due to their caregiver role should be a focus since a caregiver's unmet needs can arise from two sources: either from the personal needs of the family caregiver or from his or her care responsibilities for the people with dementia.

Reduction of Completion Time (Informal Caregiver Perspective)

The majority of the informal caregivers commented on the length of the initial versions of the assessment tool and reported

that they became a bit tired towards the end of the assessment procedure. A caregiver stated: "For the last few questions my focus was a bit lost" (informal caregiver, woman).

Areas Important to Caregivers (Informal Caregiver Perspective)

Caregivers commented on some of the areas that they found particularly important such as psychological support, mobility, social life, and psychoeducation.

A caregiver stated:

> *I would say that there should be a question for psychological support. Self-help groups should be offered locally and it should be asked whether advice or support is needed in this regard. Another thing that I would still find important is to ask how mobile you are and whether you need help in this regard. For example, I don't have a car and have to use public transport to get everywhere. And there are also people who don't even have a driver's license. And if you have to go somewhere and have to pick up things from the pharmacy (eg, incontinence pads), these are sometimes large packages that are also heavy and you have to get them home first. It would be a good idea to ask whether you need help in this regard.* [Informal caregiver, woman]

Another caregiver reported:

> *The social life is very important, my father is hardly involved in it anymore. Because of his swallowing problems, he can no longer even go to a restaurant, which is difficult.* [Informal caregiver, man]

Another cargiver stated:

> *Since we have not yet come into contact with services, I would like a lot of information so that you know what you have to do. And also so that you know why behavior changes, how people then think and what is going on inside you. I'd be very interested in that.* [Informal caregiver, man]

Regarding the content of the assessment instrument, HCPs and Alzheimer Society representatives provided information on 2 subthemes, namely, assessment structure and reduction of completion time.

Digital Tablet Usability of the Assessment Tool

Regarding the assessment's tablet usability, informal caregivers, HCPs, and Alzheimer Society representatives identified 2 subthemes, namely, simple layout and handling with slightly different subtheme categories.

Simple Layout

Informal caregivers commented on the font size, often taking out their reading glasses to be able to read the questions.

HCPs commented that one question per screen would allow the large font and button size needed. Some clinicians stated that it would be helpful to allow caregivers to go back within the assessment procedure in case they changed their mind regarding a previous answer. Going forward should only be possible if the question on the screen was completed. The majority of HCPs stated that an indication bar within the assessment procedure would be helpful for caregivers to receive information on their progress as well as how much of the assessment procedure is still in front of them.

Handling

The majority of informal caregivers reported that selecting answers by clicking worked well after adjustments were made to the font size and the size of the answer option buttons. Regarding the handling, all HCPs and Alzheimer Society representatives agreed that the selection of answers should be as straight forward as possible allowing caregivers to complete the assessment procedure without technical issues.

The adaptations made to the digital tablet-based assessment tool are shown in Figures 1 and 2. Figure 1 shows the initial, first version of the tablet-based assessment tool. Figure 2 shows the final tablet-based assessment version after the feedback was incorporated into the development by the IT team.

Figure 1. Outline of the first digital assessment version.

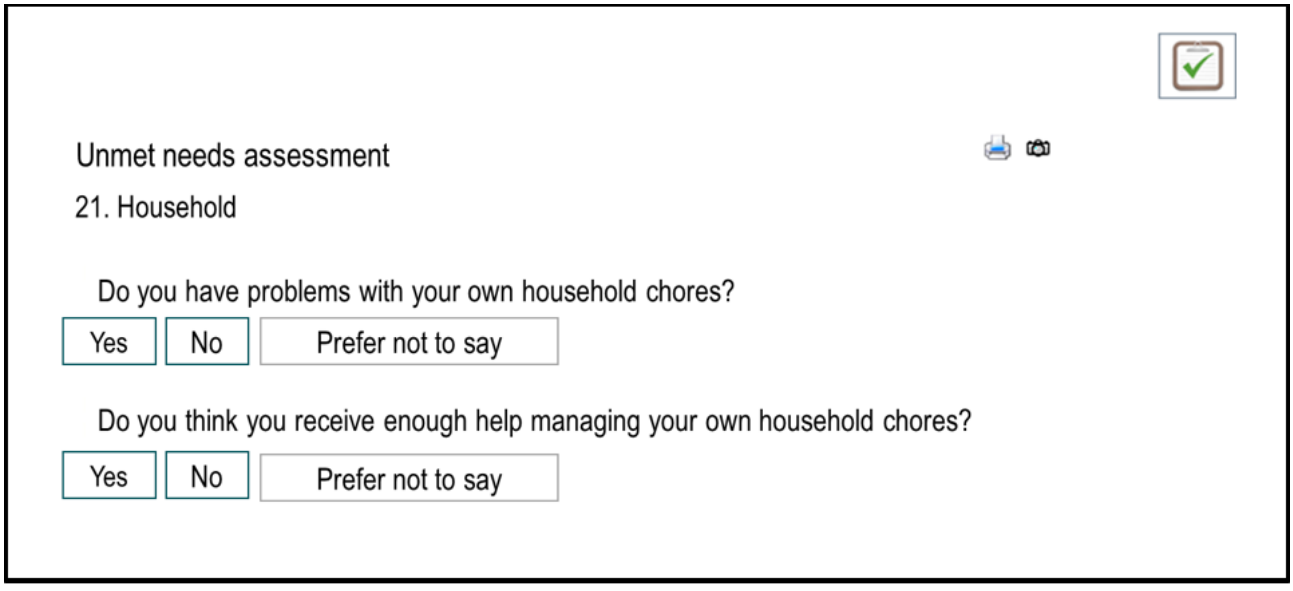

Figure 2. Outline of the final digital assessment version.

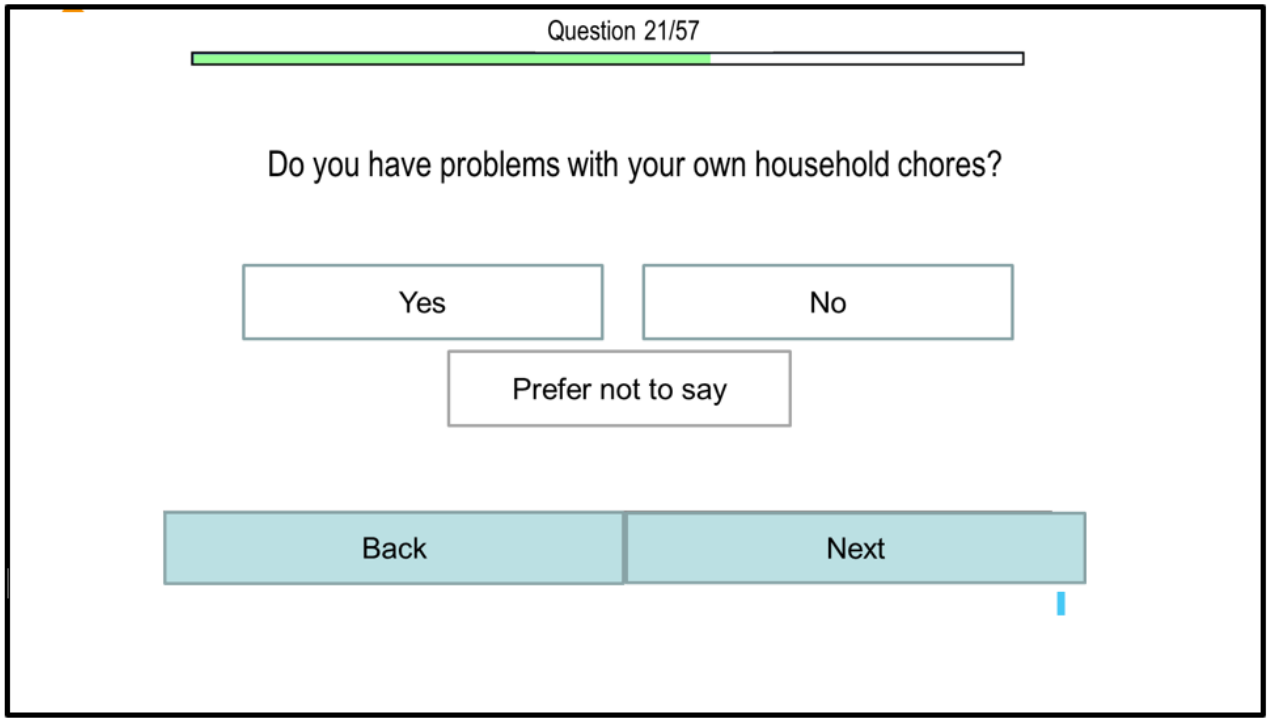
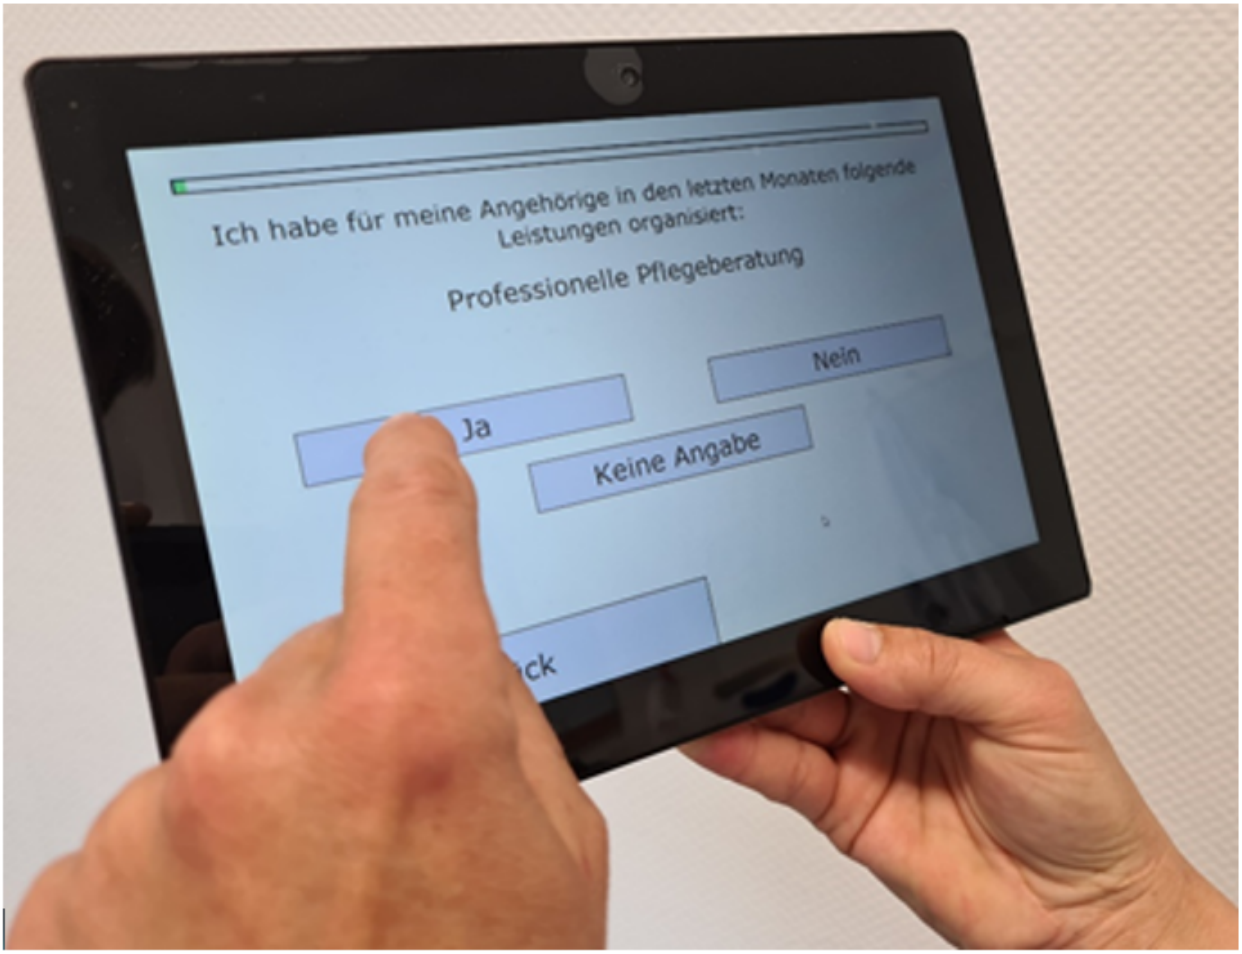


After completion, the outcome of the assessment procedure can be viewed by the study nurse as well as the GP. These professionals can then use the outcome to work together with the informal caregiver toward a reduction of the unmet needs identified. The study nurses provide the informal caregivers with a summary of the consultation where points discussed are listed.

Figure 3 depicts a caregiver filling out the digital version of the assessment tool on a tablet.

Figure 3. An informal caregiver completing the digital tablet-based assessment.



Discussion

Principal Findings

This study describes the phases of an iterative, participatory process we used to develop a digital tablet-based assessment tool designed to comprehensively identify the needs of informal caregivers of people with dementia in clinical practice. Through the collaboration with family dementia caregivers, health care professionals, and Alzheimer Society representatives, we developed a digital unmet needs assessment instrument that consists of a set of standardized instruments but also includes additional questions and adaptations that were incorporated along the iterative development process. The unmet needs assessment tool focuses on needs that can arise from two sources: either from the personal needs of the family caregiver or from the care responsibilities for people with dementia. With the contribution of informal caregivers and other stakeholders, we designed an assessment tool that covers a comprehensive range of needs considered important. At the same time, with the input of the stakeholders, the time to complete the assessment procedure was substantially reduced from the initial 37 minutes to 18 minutes. This indicates that we reached our goal of developing a comprehensive, feasible, and time-efficient assessment device.

With respect to the content of the assessment instrument, we identified important aspects regarding clarity, assessment structure, the reduction of completion time as well as content areas important to informal caregivers. We took the feedback in multiple rounds and incorporated changes along the way. Similar approaches have been conducted successfully by other research teams developing assistive technologies to support self-management of people with dementia [52].

Regarding the digital tablet-based assessment tool, we could incorporate crucial aspects regarding the layout and the handling of the tablet. The difference between our first digital assessment version compared with the final digital assessment version illustrates the importance of involving multiple perspectives, especially of those for whom the assessment instrument or technology is intended. In the literature, there is an increase of studies involving patients and stakeholders in the development or testing of technology [52-54].

The participatory approach allowed us to incorporate aspects into the development of the digital assessment tool that we, as researchers, would have missed otherwise, as can be seen in the first digital tablet-based assessment version in Figure 1 when compared with the final version in Figure 2. The input of informal caregivers, health care professionals, and Alzheimer Society representatives has broadened our perspective and has given us important hints and advice towards aspects that are important for a digital, self-completion unmet needs assessment tool. They identified questions that were unclear, suggested possible answer options, and gave us ideas on how to simplify

the navigation throughout the assessment procedure. Some researchers have used similar procedures for the development of instruments to assess patients' needs [24,47] or to facilitate implementation [19]. A review by Fischer et al [55] reports on the importance of user involvement, particularly the involvement of older adults in technology design. In their review of 40 empirical studies published between 2014 and 2018, these authors examined the consequences of involving older adults in technology design and stated that learning, adjusted design, and improved sense of participation were outcomes frequently stated in studies [55]. Not only did they report that involvement facilitated learning about the needs of older adults but it also led to the generation of new technology ideas such as a companion robot, for instance, which was not in the researchers' mind before involving older adults [55]. Newly gained insights then lead to iterative adjustments of the prototype design [55]. This was also the process that we followed making adjustments to the unmet needs assessment tool. With respect to the quality of technology developed with user involvement, Kopeć and et al [56] noticed that the overall quality of the technology could be improved. They argued that teams who involved users to develop a mobile app were rated higher by an independent jury in a competition than teams who did not. Older adults appreciated the sense of participation and felt that they were being treated as experts on their own lives and equal partners [57]. Researchers reported that involved users enjoyed their experience and some users described their involvement as "happy memories" [58-60].

In contrast to already existing unmet needs assessment instruments, our digital assessment tool identifies a informal caregiver's self-reported unmet needs and ties them directly to interventions most of which are offered within the German health care system. Through the matching process of possible unmet needs with interventions in phase 1 of our assessment development process, we aimed to overcome the pitfalls of identifying problem-centered needs without having support services to meet them at hand. In addition, the digital assessment tool acknowledges the intertwined nature of the dyad, namely the informal caregiver and the person with dementia focusing on not only the health and support needs of the caregiver but also the caregiver's care responsibilities. Although we did not include the CNA-D, we did compare the content and ensured that no important aspect was missed in the assessment procedure.

Limitations

The stakeholders who contributed to the development of the assessment tool were a convenience sample. We have asked informal caregivers, health care professionals and Alzheimer Society representatives who either visited a memory clinic with their significant other, worked at the memory clinic or who were already known to us due to previous collaborations. Furthermore, the sample is limited to people living in a specific region in Northern Germany (Mecklenburg-Western Pomerania). In addition, our level of involvement was limited to stakeholders sharing their feedback on the assessment tool, which is only 1 of the 3 levels of involvement [61]. The tendency to involve stakeholders only in some rather than all levels of involvement was also highlighted by Fischer et al [55] arguing for further research on the actual practices of user involvement. For future projects, a higher level of involvement is sought, especially since current results indicate that an elaborated, theory-based participatory approach including people with dementia, informal caregivers and regional stakeholders might raise the chances of successful implementation in routine care [19].

Conclusion

Our study has shown the feasibility and success of user involvement in the development of an assessment tool for identifying the unmet needs of people with dementia and their informal caregivers. By presenting our approach, we hope to motivate researchers worldwide to expand stakeholder involvement in the early stages of studies. To facilitate this, the questionnaire will be made available to researchers on the homepage of the Network for Translational Dementia Care Research. Further evaluations, such as the acceptance of the tool from the perspective of the study nurses and GPs, are currently being evaluated and will be published separately.

Acknowledgments

The authors would like to acknowledge the input of all stakeholders for their time and perspective. This work was supported by the Federal Joint Committee (G-BA) – Innovation Fund (Gemeinsamer Bundesausschuss/Innovationsausschuss; funding code: 01VSF18030). The ministry had no role in the design of this study and will not have any role during the implementation, analyses, interpretation of the data, or publication of results.

Data Availability

The datasets generated or analyzed during this study are available from the first author on reasonable request.

Authors' Contributions

Each author has made substantial contributions to this work, has approved the submitted version and has agreed both to be personally accountable for their own contributions and to ensure that questions related to the accuracy or integrity of any part of the work, even ones in which the author was not personally involved, are appropriately investigated, resolved, and the resolution documented in the literature.

Abstract

Background: Web-based tools have gained popularity to inform and empower individuals in advance care planning. We have developed an interactive website tailored to the unique needs of people with dementia and their families to support advance care planning. This website aims to break away from the rigid pathways shown in other tools that support advance care planning, in which advance care planning is shown as a linear process from information to reflection, communication, and documentation.

Objective: This study aimed to assess the website's usage by people with dementia and their family caregivers, identify distinct user engagement patterns, and visualize how users navigated the website.

Methods: We analyzed the website's log data obtained from an 8-week evaluation study of the site. Interactions with the website were collected in log data files and included visited web pages or clicked-on hyperlinks. Distinct user engagement patterns were identified using K-means clustering process mining, a technique that extracts insights from log data to model and visualize workflows, was applied to visualize user pathways through the website.

Results: A total of 52 participants, 21 individuals with dementia and their family caregivers as dyads and 10 family caregivers were included in the study. Throughout the 8-week study, users spent an average of 35.3 (SD 82.9) minutes over 5.5 (SD 3.4) unique days on the website. Family caregivers mostly used the website (alone or with a person with dementia) throughout the 8-week study. Only 3 people with dementia used it on their own. In total, 3 distinct engagement patterns emerged: low, moderate, and high. Low-engagement participants spent less time on the website during the 8 weeks, following a linear path from information to communication to documentation. Moderate- and high-engagement users showed more dynamic patterns, frequently navigating between information pages and communication tools to facilitate exploration of aspects related to advance care planning.

Conclusions: The diverse engagement patterns underscore the need for personalized support in advance care planning and challenge the conventional linear advance care planning representations found in other web-based tools.

dementia; advance care planning; user engagement; web-based tool; care; website; caregiver; communication; tool; online

Introduction

Advance care planning is a communication process between patients, families, and health care professionals to "define goals and preferences for future care and treatment" [1]. This process holds particular relevance in dementia [2]. The cognitive decline in dementia highlights the need for early initiation of advance care planning, enabling people with dementia to reflect on and express their preferences for future care and treatments [3-5]. While existing definitions of advance care planning often focus on medical care decisions [6], people with dementia and their families have emphasized that it should include exploring what matters now and in the future, including nonmedical aspects of care [7-10]. Furthermore, people with dementia and their

families have expressed a need to discuss future care together [7]. This aligns with the recently introduced public health to advance care planning, emphasizing a shift toward a social focus on "what matters most to people" rather than the current emphasis on end-of-life decision making and underlining the need to support conversations in the family context [11].

To support advance care planning within the family context, interactive web-based tools like websites or apps have been promoted [12]; however, despite their proven benefits in other populations, there is a noticeable absence of tools tailored to the specific needs of people with dementia and their families [13-15]. To address this gap, we developed a website for and with people with dementia and their families [16-19]. This website deviates from the structured linear pathways found in other tools to support advance care planning [15]. Such tools adhere to a stepwise procedure, often commencing with information provision, prompting reflection, followed by communication, and concluding with documentation, commonly in the form of advance directives. For example, in some cases, users must complete or make an explicit effort to skip a step before being able to proceed to the next step, eg, users cannot access certain features such as communication tools or documentation forms without first completing previous tasks, for example, users have to follow a linear pathway when navigating the website [15,20]. In contrast, our website is designed to offer flexibility, allowing users to engage with the content in any way they choose. There are no predefined steps or sequences to follow, and users can access all features, such as communication tools and documentation forms, without needing to complete any previous tasks [16].

Following the development of the website to support advance care planning, we performed an 8-week evaluation study involving people with mild to moderate dementia and their family caregivers [17,18]. The primary focus of this evaluation was to assess the usability, acceptability, feasibility, experiences, and outcomes of using the website [17,18]. Participants in the evaluation study found that the website supports advance care planning [17,18]. After 8 weeks, participants exhibited improved advance care planning knowledge, self-efficacy, and skills [17,18].

Beyond this evaluation, gaining insights into the website's user engagement and usage patterns is crucial to enhance our understanding of how people with dementia and their families use a website to support advance care planning in the family context, how they engage with it and how single users and dyadic users differ (ie, people with dementia together with their family caregiver). This knowledge will inform enhancements to the website's design and functionality by highlighting user needs in digital health interventions, ultimately improving support for families navigating advance care planning. Therefore, this study aims to: explore how people with dementia and their family caregivers used the advance care planning support website during an 8-week evaluation study; explore whether and which user behavior clusters can be typified based on the engagement of people with dementia and their family caregivers with the website; and explore and visualize user pathways of the identified user behavior clusters, that is, how the different user clusters of people with dementia and their family caregivers navigate through the website.

Methods

Study design

This study quantitatively analyzed web log data from a convergent parallel mixed methods evaluation study of a website designed to support people with dementia and their family caregivers in advance care planning. Web log data was collected during an 8-week evaluation study to capture participants' interactions with the website, for example, time spent on the website and what pages were visited. This log data was used to explore the website's usage by people with dementia and their family caregivers, which user behavior clusters can be typified and to visualize user pathways. The protocol, including the objective to explore usage patterns of the website, as well as the main results of the evaluation study, have been published elsewhere [17,18]

The Development of the Advance Care Planning Support Website

The development of the website followed a user-centred, iterative design process, ensuring alignment with the needs of people with dementia and their families. The website was developed to provide information and support for people with dementia and their family caregivers in advance care planning [16]. Furthermore, the website was designed with flexible navigation options, allowing users to explore different sections at their own pace rather than following a linear, step-by-step approach. This was particularly important given the varying levels of readiness among users to engage with sensitive topics such as future care preferences [8,16].

The website includes advance care planning information, information about legal frameworks, communication tips, and documentation sections. Furthermore, it provides accessibility features, such as text-to-speech and text enlargement and 2 interactive communication tools, an "Interactive Card Tool" based on the recently developed paper-based version of the Levenswensen (Life Wishes) cards and a fill-in tool "Thinking Now About Later," that guides users through a reflective process to help users think and talk about and write down their preferences for the present and future (Multimedia Appendices 1 and 2). The results of the evaluation study and experiences with the interactive communication tools, have been published elsewhere [16,18,21].

Participants, Recruitment and Setting

People with mild to moderate dementia, including both early and late onset, along with their family caregivers as dyads or the family caregiver alone, were recruited [17]. To be eligible, participants needed to meet the criteria shown in Textbox 1 [17]
.

Textbox 1. Inclusion criteria for the study.

Both people with dementia and their family caregivers:

- Express interest in and willingness to test the website to support advance care planning.
- Provide consent for study participation.
- Proficient in speaking and understanding Dutch.
- Own a device (laptop, tablet, mobile phone, etc).

People with dementia:

- Diagnosed with young- or late-onset dementia.

Family caregivers:

- Actively involved in the care (physical, emotional, social, etc) of the person with dementia.

For participants recruited as dyads, at least one had to be capable of navigating the website. For instance, the person with dementia and the family caregiver could not both have visual impairments or other disabilities hindering interaction with the advance care planning website. Participants were recruited through dementia care organizations and memory clinic neurologists. Eligible participants with a confirmed dementia diagnosis were identified by health care professionals. People with dementia who were interested in the study contacted the researcher, received study information, and, if still interested after receiving the study information, were offered an appointment to perform the eligibility screening and provide informed consent. The recruitment process is described in more detail in the study protocol that is published elsewhere [17]. The study was conducted in Flanders, the Dutch-speaking region of Belgium.

Data Collection Procedures

Between October 2022 and May 2023, 52 people participated in the evaluation study: 21 dyads, that is, 21 people with dementia and 21 family caregivers, and 10 family caregivers alone. Information on sociodemographic data, including age, gender, computer literacy, type of diagnosis and date, was gathered through a survey assessed at the start of the 8 weeks [17,18]. Participants were granted access to the website after providing informed consent and completing baseline data collection. They were informed that they could use the website freely over an 8-week period, choosing how and when to engage with it according to their preferences [17].

To capture the usage by the participants during the 8-week study, there was a continuous collection of log data. Usage refers to how people with dementia and family caregivers engage with the advance care planning website. The log data captured what pages were visited, time spent on each page, interaction with content or functions, frequency of visits to each page, and the search queries used. Upon accessing the website, participants were prompted to identify themselves through a pop-up question, requiring them to fill in their study ID and specify whether they were a person with dementia, a family caregiver, or engaging together as a dyad. A detailed study protocol of the evaluation study is published elsewhere [8].

Data Analysis

Overview

Log data of the advance care planning website were analyzed using the programming language R (version 4.2.3, R Studio). The log data was saved in 3 files, application and access logs and a file to save the interactions with the interactive communication tools. First, the 3 log datasets were cleaned by eliminating irrelevant data, such as admin and php requests. The application logs were further filtered to include only valid study IDs used by the participants. Study IDs were then added to the access logs based on cross matching with IP addresses. The access and application logs were combined, and additional information from the third dataset regarding the completion of interactive communication tools was incorporated by matching IP addresses to study IDs.

Assessing the Extent to Which the Website Was Used

First, the interactions with the website were summarized by time spent on the website, pages visited, and who visited. This analysis focused on usage patterns, which provided an initial understanding of the variability in engagement.

Identifying Distinct Behavioral Clusters

After, the data underwent K-means clustering. Clustering the data aimed to identify behavioral or interaction patterns that typify user engagement. The 6 features derived from the summary data were used for clustering: total interactions, unique days, duration of use, total clicks on communication, information, and documentation pages. The R package “caret” was used to normalize the data using min-max normalization, converting variables to a range between 0 and 1 [22]. Usage frequency emerged as the key differentiating factor among participants. The “NbClust” package was then used to compare summary statistics and determine the optimal number of clusters, using 30 indices to determine the optimal number of clusters (k) between 2 and 10 based on these metrics [23]. The “NbClust” package indicated that the data could be best classified into 3 clusters, which were named after usage frequency of participants, for example , low, moderate, and high engagement levels. Subsequently, the k-means algorithm was applied to the data for k clusters. Principal component analysis (PCA) was used for data visualization to reduce the multiple features to 2 dimensions. Finally, Kruskal-Wallis rank sum tests

and χ^2 tests were conducted to evaluate the significant differences between features for each cluster, providing further insights into the characteristics of the identified user clusters.

Identification of User Pathways

To visualize how users navigated through the website, we applied process mining techniques using the R package BupaR. This allowed us to map and analyze the various paths users followed across the site's different sections [24]. Log data were filtered to remove redundant information (taken out: change font size, contrast, privacy policy, read speaker, print, and other). First, a process matrix, which is a 2-dimensional matrix showing the flows between activities, was generated to visualize the entire log dataset [25]. After, individual process maps were produced per study ID to show the path taken by participants. Finally, the individual paths were compared with the IDs per cluster to find similarities and differences between the participants' paths in each cluster.

Ethical Considerations

The research protocol was submitted to the Medical Ethics Committee of Brussels university hospital (UZ Brussel) and received ethical approval (BUN 1432022000179). All participants provided informed consent, and the study was conducted in accordance with the relevant ethical guidelines and regulations. To ensure privacy and confidentiality, all participant data were de-identified prior to analysis. Protective measures, such as secure data storage and restricted access to personal information, were implemented to safeguard participant privacy throughout the study.

Results

Overview

In total, 52 participants with 31 study IDs were included (21 dyads and 10 family caregivers), consisting of 21 people with dementia and 31 family caregivers. Ten family caregivers participated alone, either because the person with dementia was unable to provide informed consent (6/10) or chose not to participate (4/10). The average age of people with dementia was 62.8 (SD 10.4) years, with 42.8% (9/21) being female. Among family caregivers, 68% (21/31) were female, with an average age of 62.1 (SD 10.9) years. Family caregivers reported an average computer literacy score of 7.5 (on a scale from 1 to 10, with higher scores indicating greater self-reported computer literacy), while people with dementia had an average score of 4 (Table 1).

Table . Description of the study population.

Variables		Persons with dementia (n=21)	Family caregivers (n=31)
Sex (female), n		9	21
Age (years), mean (SD)		62.1 (10.9)	62.8 (10.4)
Relationship, n			
	Partners[a]	18	25
	Parent (in law)-child	3	6
Profession, n			
	Employed	1	16
	Retired	20[b]	15
Computer literacy[c], mean (SD)		62.1 (10.9)	62.8 (10.4)
Dementia diagnosis[d], n			
	Alzheimer disease	15	20
	Vascular dementia	1	3
	Frontotemporal dementia	3	3
	Lewy body dementia	1	1
	Parkinson dementia	0	1
	I do not know	1	3

[a]Married, living together or in a romantic relationship.

[b]Six of the retired persons with dementia were forced to take early retirement because of their diagnoses.

[c]Self-evaluation on a scale from 1 (no computer skills) to 10 (excellent computer skills).

[d]Dates of diagnoses: January 2013 to December 2022.

Website Usage

Each study ID (n=31) was logged at least once in the log data, indicating at least 1 visit by 1 or both dyad members and by each family caregiver who participated alone. In 10 study IDs, both the family caregiver and dyad used the website. In 15 instances, only the caregiver accessed it and in 3 cases, solely the dyad engaged with the website. In addition, 3 occurrences

involved mixed usage, with indications of the family caregiver, dyad, or person with dementia using the website. The total number of unique interactions by all users (n=31) with the website was 1799 (ie, the total interaction data points), encompassing information searches, clicks, and use of interactive elements. On average, users had 58 (SD 57) interactions over the 8 weeks. The total duration spent on the website during the 8 weeks was 35.3 (SD 82.9) minutes, and, on average, people used the website on 5.5 (SD 3.4) unique days of the 8-week study period.

User interactions revealed that family caregivers had the highest overall number of interactions (757), followed by dyads (235) and people with dementia alone (103). We faced difficulty attributing the information to specific user types for the other 701 interactions documented in the access log file. These unidentified usages per user type arose from difficulties linking interactions with corresponding user types when users left their browsers open for extended periods. The webpage "Advance Care Planning: What Is It?" was visited most (n=304). Followed by the glossary section (209), "Advance Care Planning: Thinking and Talking About Later" (277), "Advance Care Planning: Writing It Down for Later" (259) and the frequently asked questions section (122). The 2 interactive communication tools were used 136 (Thinking Now About Later) and 91 (Levenswensen cards) times.

Identifying Typical User Behaviors by Clustering

To determine the optimal number of clusters, we applied NbClust with 30 indices, revealing that 8 favored 2 clusters and 8 indicated 3 clusters. Following the majority rule, we opted for 3 clusters, each assigned to study IDs reflecting diverse user engagement patterns. Table 2 summarizes each cluster's characteristics. To showcase the most-visited web pages by the clusters, we categorized all pages into 10 categories (Figure 1; Multimedia Appendix 1 visually shows the web pages corresponding to the categories).

Table . Overview of the characteristics of use of the website of each cluster.

Characteristics	Moderate engagement level	Low engagement level	High engagement level	*P* value
Size, study ID/n[a] (%)	15/21 (45)	5/10 (21)	11/16 (34)	—[b]
Total interactions[c], mean (SD)	50 (13)	21 (9)	86 (15)	<0.001[d]
Unique days, mean (SD)	4.4 (1.5)	1.6 (0.5)	8.7 (3.3)	0.004[d]
Range of use (days), mean (SD)[e]	56.7 (19.3)	9.8 (19.2)	65.6 (16.9)	<0.001[d]
Communication pages visited, mean (SD)	17 (7)	5 (3)	28 (10)	<0.001[d]
Documentation pages visited, mean (SD)	7 (4)	6 (4)	18 (4)	<0.001[d]
Information pages visited, mean (SD)	22 (10)	7 (5)	34 (13)	<0.001[d]
Total number of interactions per user type, n				<0.001[g]
Caregiver	420	27	310	
Person with dementia	0	0	103	
Dyad	124	33	88	
Family caregiver and person with dementia[f]	204	54	452	

[a]n is the number of users (N=46 because 5 people with dementia did not use the website or participate anymore).

[b]Not applicable.

[c]Interaction is any movement of the user on the website. This can be clicking on a hyperlink, watching a video, opening a page, or printing the web page.

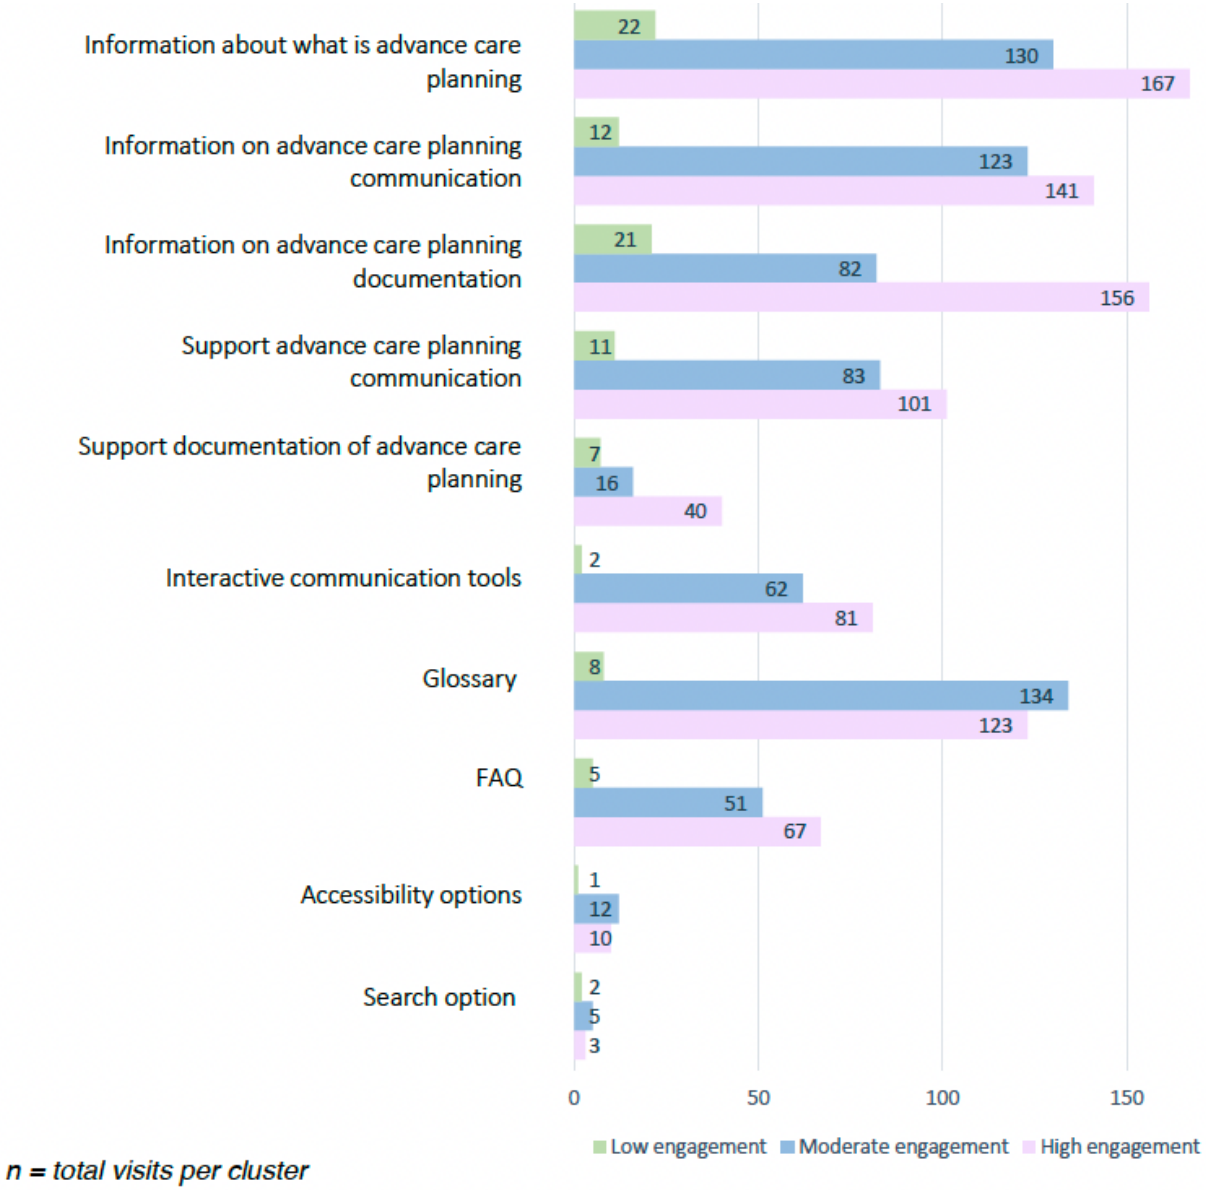
[d]χ^2 test.

[e]From the first day of use until the last day. For example, cluster moderate engagement started using the website, and, on average, the last usage was 9.8 days later.

[f]When the IP address could not be matched with the date or time of the filled-in study ID.

[g]Kruskal-Wallis rank sum test.

Figure 1. Overview of the most-visited web pages by the 3 clusters. FAQ: frequently asked questions.



Cluster low engagement (5 participants) exhibited the fewest interactions (mean of 21), shorter duration (mean of 9.8 days), and accessed fewer pages. Cluster moderate engagement (15 participants) had a mean of 50 interactions, visited for 4.4 unique days, with a use duration of approximately 56.7 days (Table 2). Cluster high engagement (11 participants) demonstrated the highest engagement, with the highest total interactions (mean of 86), longer duration (mean of 65.6 days), accessing more diverse pages and including the 3 people with dementia who used the website alone. Statistically significant *P* values underscore distinct engagement patterns among the clusters (Table 2).

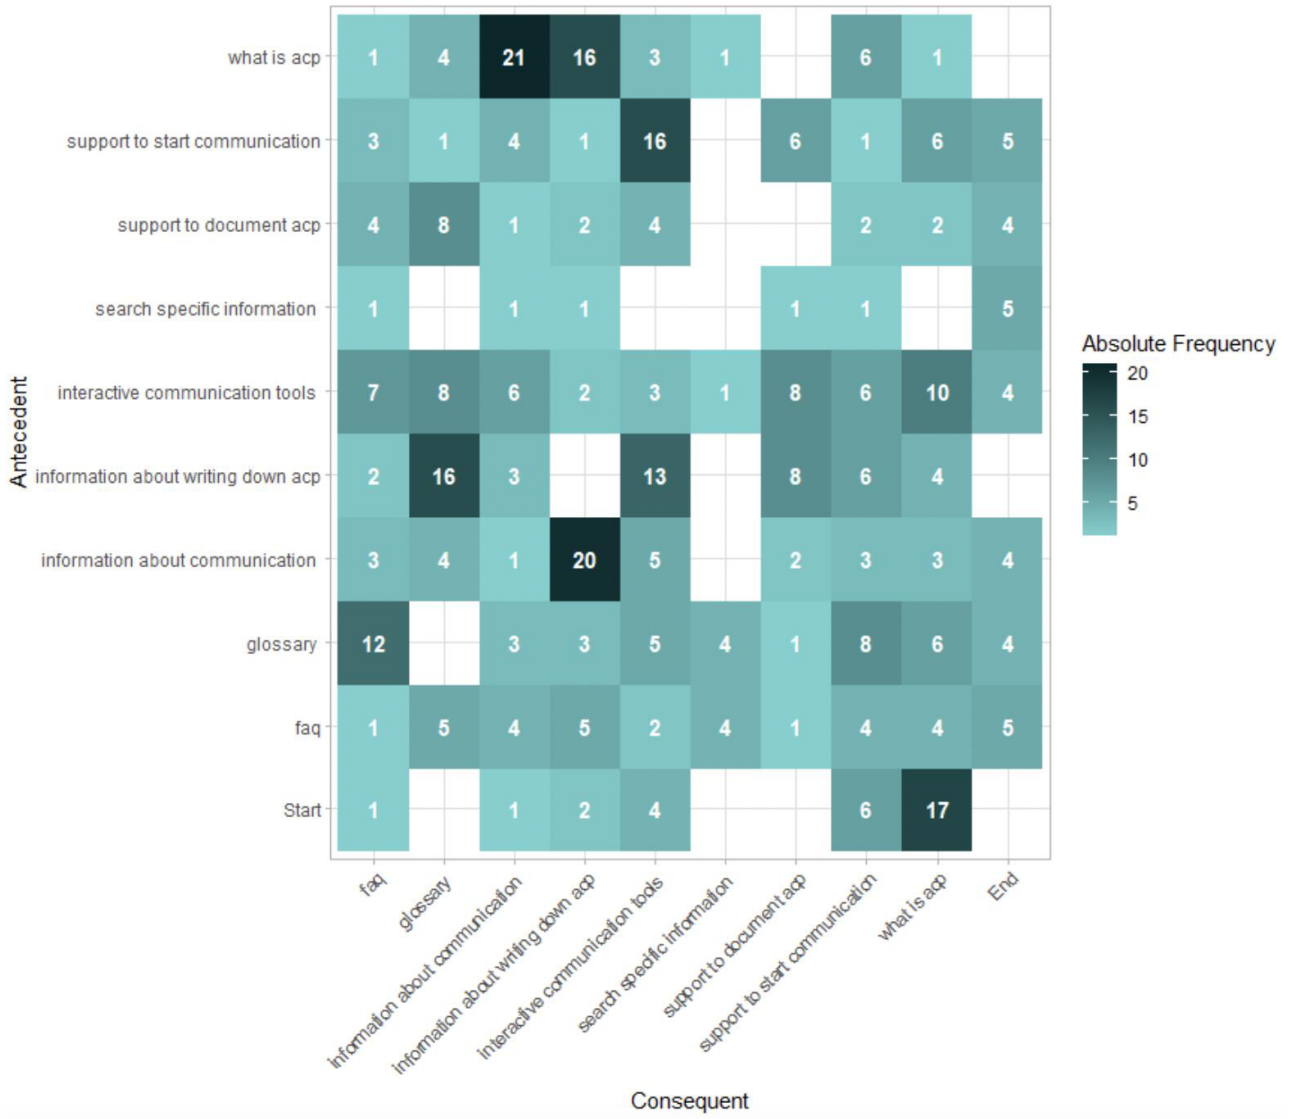
Participants across all 3 clusters predominantly visited the "what is advance care planning" web page the most. Low-engagement participants mostly focused on the information pages, especially the documentation information and showed limited interest in interactive tools. Moderate engagement participants visited mostly the advance care planning information pages, frequently using the glossary and accessibility features like contrast and text-to-speech, distinguishing their usage from other clusters. In the high-engagement cluster, participants explored information, communication and documentation pages, actively using interactive communication tools.

Identification of User Pathways of the Identified User Behavior

To identify the user pathways, we first look at the overall pathways of users using a process matrix (Figure 2). The process matrix is a two-dimensional representation that illustrates the flow between the web pages that users have visited. The matrix is organized with antecedent events followed by the consequent events. The primary pathway, observed in 21 instances, initiates with a visit to the "What is advance care planning" page, followed by navigating to a subsequent page providing "information about communication." Significantly, users frequently started their pathway on informative pages, such as "what is advance care planning," "information on communication," or "Information on documentation." Subsequently, they progress to explore additional information pages. Noteworthy is the observation that users typically visit

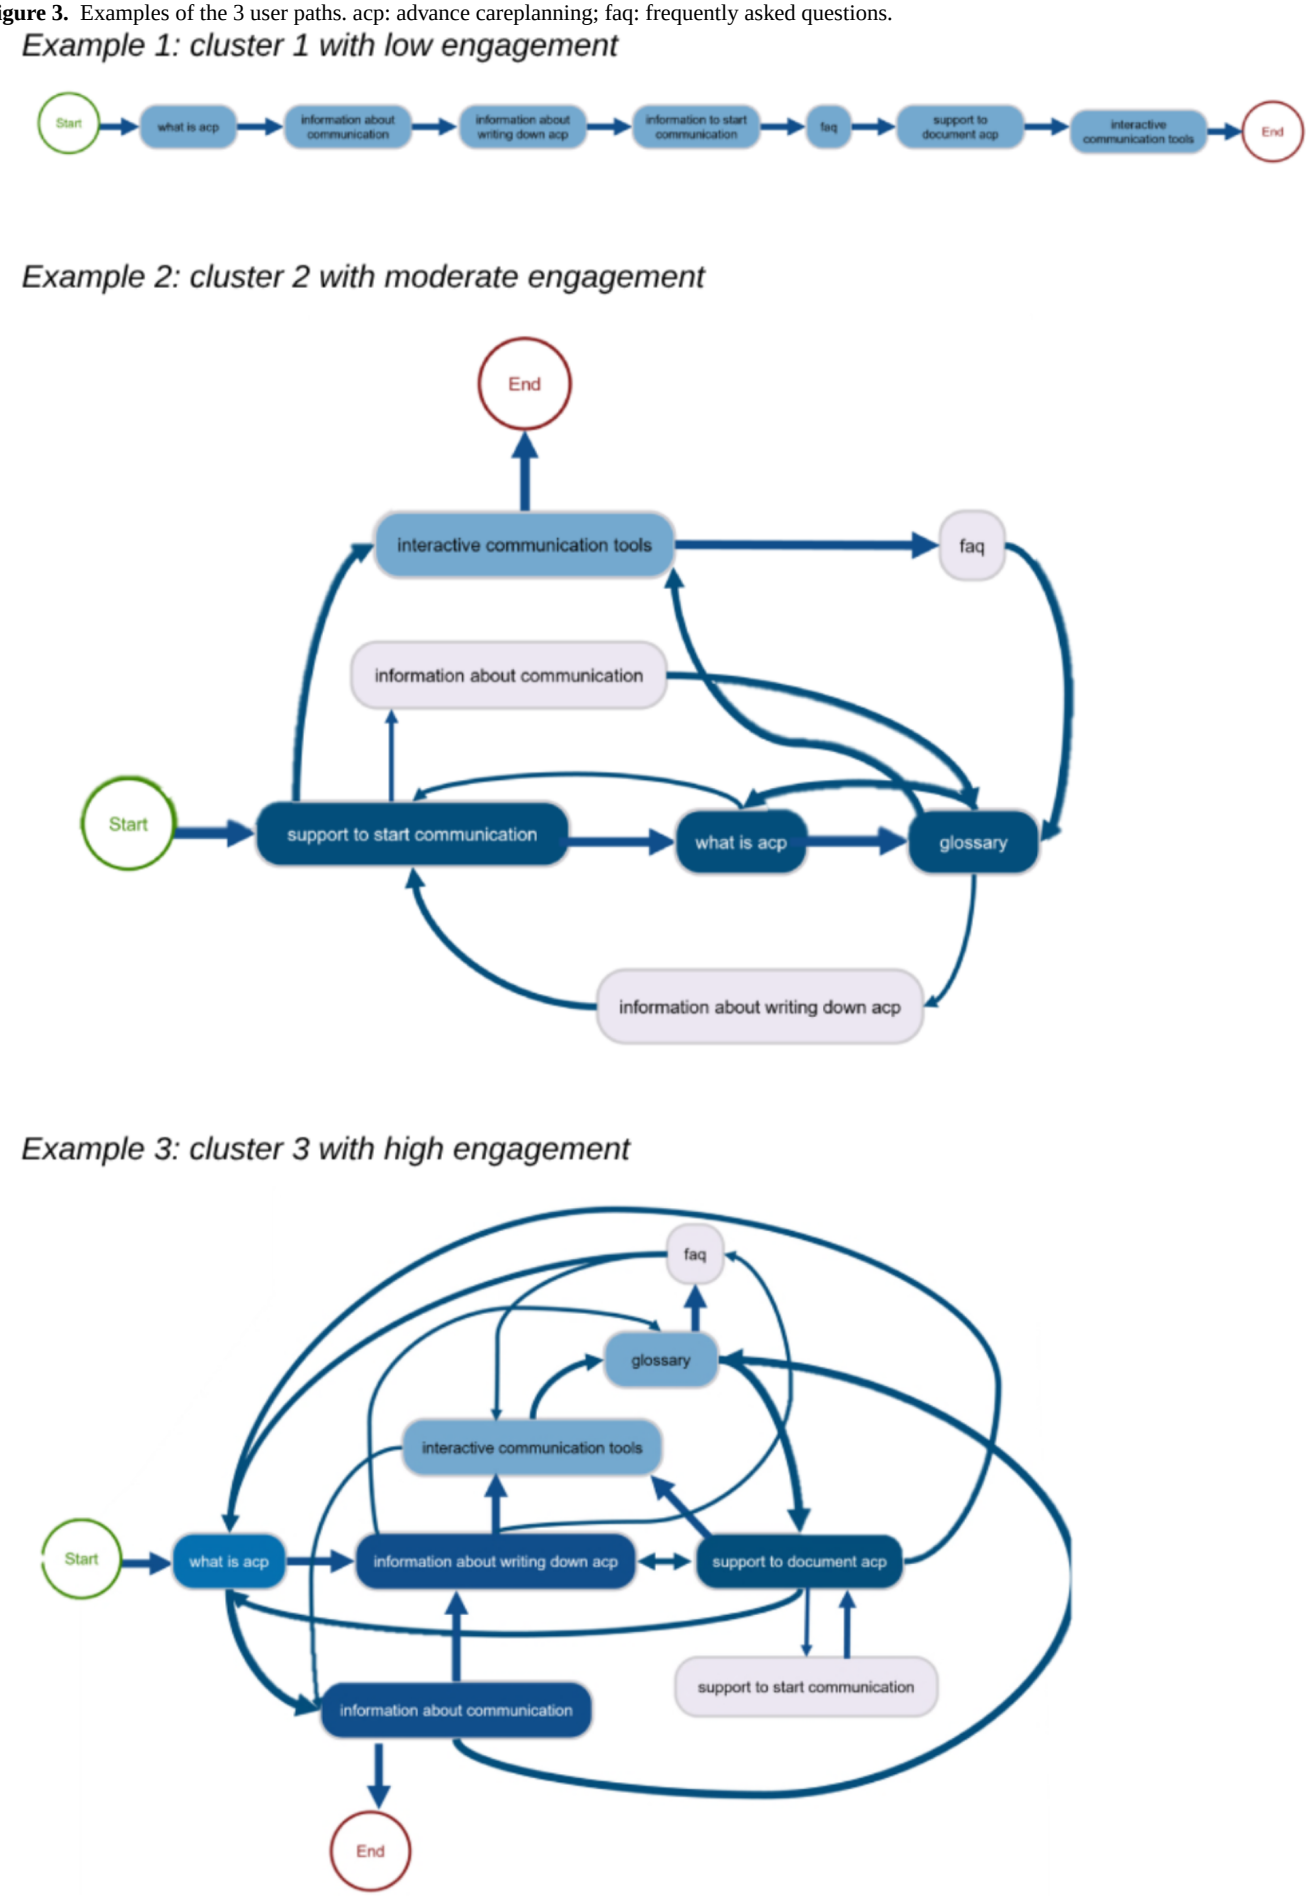
pages providing information about communication or documentation before engaging with the interactive communication tools.

Figure 2. Identification of overall user pathways. acp: advance care planning; FAQ: frequently asked questions.



Then, the user pathways of the identified user behavior clusters were identified (Figure 3). Low-engagement participants (Figure 3, example 1) displayed a linear and direct browsing style, rarely revisiting previous pages during navigation. In contrast, the participants with moderate and high engagement (Figure 3, examples 2 and 3) explored the website by visiting pages sequentially, occasionally revisiting previously viewed pages. High engagement extensively explored various pages, moving between information and guidance pages. Participants with moderate engagement involved frequent transitions between pages but less often than those with high engagement.

Figure 3. Examples of the 3 user paths. acp: advance careplanning; faq: frequently asked questions.



Discussion

Principal Findings

The analyses of the log data of an 8-week evaluation study of a website to support people with dementia and their families in advance care planning showed that family caregivers used the website most often, either alone or with a person with dementia, that is, dyad. Three distinct engagement patterns emerged in this study: low, moderate, and high. Low-engagement users tended to follow a more linear path on the website, while moderate- and high-engagement users displayed a more dynamic engagement, exploring the website in diverse ways.

Flexible user navigation patterns were evident in our study, challenging the conventional linear advance care planning representations found in other web-based tools in which users go through a stepwise process, typically starting with information provision, prompting reflection, moving on to communication, and concluding with documentation in the form of advance directives [15]. This rigid structure, embedded in the design of other ACP websites, may restrict easy access to subsequent features or content until earlier steps are completed. While this structured pathway might work for some users, it assumes that everyone is ready to follow the same route through the ACP process, which may not always be the case [7,8,26]. In our study, low-engagement users tended to follow a more linear pathway. However, those with moderate or high engagement demonstrated more dynamic and varied usage patterns. Some users initiated their engagement by seeking information, while others prioritized documentation or directly accessed communication tools. This flexibility of navigation aligns with feedback from family caregivers during the website's development process, which emphasized the importance of allowing users to navigate at their own pace, rather than following a rigid, linear path [8]. This flexibility allowed for personalized engagement, as different users may be at different stages of readiness to engage with sensitive topics, such as future care planning. Furthermore, this approach aligns with broader technological research [7,10,26], which shows that family caregivers prefer flexible navigation in internet-based tools [27,28]. These findings suggest a need for a more flexible approach, indicating that users should have the freedom to navigate tools that align best with their needs, which is also supported by other research [5,26,29]. This also aligns with Belgian clinical guidelines [30], explicitly mentioning that health care professionals should tailor advance care planning in dementia, including style and content, to the "person's level and rhythm."

Despite participants' expressed interest in advance care planning in the evaluation study, people with dementia rarely engaged with the website on their own. Family caregivers and the person with dementia did engage together, emphasizing the family's importance. This finding is not necessarily surprising as much literature points at the importance of family in a dementia trajectory. A recently published consensus definition on advance care planning in dementia also highlighted family as highly important and specific in this population [6,31]. Regarding the use or uptake of websites among people with dementia, involving family caregivers can play a facilitating role; however, it is essential to acknowledge that not all people with dementia have family caregivers or families directly engaged in their care [32]. Furthermore, overreliance on family caregivers may unintentionally hinder independent usage, potentially undermining autonomy. Therefore, achieving an inclusive environment necessitates balancing involving family caregivers and promoting self-usage.

Strengths and Limitations of the Study

This study has several strengths that contribute to the robustness of our study's findings. Using log data, this study is the first to examine user engagement of people with dementia and their families with a website to support advance care planning. It offers a comprehensive understanding of their specific usage patterns. The elimination of recall bias is another key strength, as log data provided an accurate account of how users engaged with the website. The study also has limitations with regard to the data used. We encountered difficulty identifying the specific type of user for all log data because not all access logs could be matched with the date or time of the filled-in type of user in the application log. In addition, due to a 1-month retention period for log data, a small portion of data (7 days with interactions from 2 users, as indicated in Google Analytics) was lost as it was not downloaded before deletion from the server. Another limitation is the relatively small dataset for our log data analyses. Specifically, the number of participants with dementia who accessed the website independently was small what limits our ability to make comparisons in usage patterns between people with dementia, family caregivers, and dyads. Further research with a larger sample of people with dementia, including both independent and caregiver-supported users, is needed to enhance the robustness of the findings and provide stronger insights into their engagement patterns. Finally, a limitation arises from self-selection bias in user type; for example, users might identify as "family caregivers" while engaging together, and vice versa, introducing variability that could impact the accuracy of findings.

Conclusions

This study offers insights in how people with dementia and their family caregivers use a website designed to support them in advance care planning. The findings show that family caregivers are the website's primary users, often engaging with the website alone or together with the person with dementia. Three distinct user engagement patterns, low, moderate, and high engagement, were identified, with more dynamic navigation observed among high-engagement users, particularly those using interactive communication tools. These findings underscore the need for flexible user pathways in online advance care planning tools, allowing personalized navigation. Future research with a larger and more diverse sample of persons with dementia is necessary to confirm these findings and allow for more detailed comparisons across different user groups.

Acknowledgments

We would like to thank all participants for their time and effort. We thank the neurologists working in memory clinics, the Expertise Centrum Dementia Flanders, Alzheimer Liga Flanders, and Het Ventiel for their efforts in recruiting participants. This study is part of the project "CAPACITY: Flanders Project to Develop Capacity in Palliative Care Across Society," a collaboration between the Vrije Universiteit Brussel, Ghent University, and the Catholic University Leuven, Belgium. This study is supported by a grant from the Research Foundation – Flanders (file number S002219N). The research presented in this paper was carried out as part of the DISTINCT project, a Marie Curie Innovative Training Network (ITN), H2020-MSCA-ITN-2018, under grant agreement number 813196.

Abstract

Background: Providing ongoing support to the increasing number of caregivers as their needs change in the long-term course of dementia is a severe challenge to any health care system. Conversational artificial intelligence (AI) operating 24/7 may help to tackle this problem.

Objective: This study describes the development of a generative AI chatbot—the PDC30 Chatbot—and evaluates its acceptability in a mixed methods study.

Methods: The PDC30 Chatbot was developed using the GPT-4o large language model, with a personality agent to constrain its behavior to provide advice on dementia caregiving based on the Positive Dementia Caregiving in 30 Days Guidebook—a laypeople's resource based on a validated training manual for dementia caregivers. The PDC30 Chatbot's responses to 21 common questions were compared with those of ChatGPT and another chatbot (called Chatbot-B) as standards of reference. Chatbot-B was constructed using PDC30 Chatbot's architecture but replaced the latter's knowledge base with a collection of authoritative sources, including the World Health Organization's iSupport, By Us For Us Guides, and 185 web pages or manuals by Alzheimer's Association, National Institute on Aging, and UK Alzheimer's Society. In the next phase, to assess the acceptability of the PDC30 Chatbot, 21 family caregivers used the PDC30 Chatbot for two weeks and provided ratings and comments on its acceptability.

Results: Among the three chatbots, ChatGPT's responses tended to be repetitive and not specific enough. PDC30 Chatbot and Chatbot-B, by virtue of their design, produced highly context-sensitive advice, with the former performing slightly better when the questions conveyed significant psychological distress on the part of the caregiver. In the acceptability study, caregivers found the PDC30 Chatbot highly user-friendly, and its responses quite helpful and easy to understand. They were rather satisfied with it and would strongly recommend it to other caregivers. During the 2-week trial period, the majority used the chatbot more than once per day. Thematic analysis of their written feedback revealed three major themes: helpfulness, accessibility, and improved attitude toward AI.

Conclusions: The PDC30 Chatbot provides quality responses to caregiver questions, which are well-received by caregivers. Conversational AI is a viable approach to improve the support of caregivers.

Introduction

Background

How to leverage technological innovation to improve support in the protracted journey of caring for someone with dementia has been identified as one of the top priorities by dementia care researchers, practitioners, and policy makers [1,2]. Dementia family caregiving is widely regarded as a prototype of chronic stress [3,4]. With the increasing loss of abilities in persons with dementia, family members transition from a "companion" to a more heavy-duty caregiver. Initially, family members may want to know more about the condition and what to plan ahead of time. As the relative's condition worsens, tips about handling different behaviors or situations and helping the relative with activities of daily living become more relevant, with end-of-life issues on the horizon further down the road. Thus, caregivers' needs change over time but are often given a time-limited (eg, 8 weekly sessions) standardized training program disregarding their specific concerns [5,6]. While some open-minded caregivers may be curious to find out more about the subject matter, others feel compelled to go through materials irrelevant to their immediate concerns (or things they already know) [7]. Moreover, traditional interventions are packaged to be delivered in regular blocks of time, which may not fit into the busy and often unpredictable schedule of many caregivers [5,6]. In addition, traditional intervention modalities often rely on face-to-face contact, a problem brutally exposed during the COVID-19 pandemic [8,9], but a problem that is generally applicable to those in rural areas.

Although over two-thirds of caregivers in a large UK survey [10] indicated an interest in using technological tools to support their health and well-being, as well as their caregiving role, few such tools are available for dementia family caregivers. A major reason cited by the respondents in support of technological support was "being able to use digital tools quickly to find answers on a regular basis" [10]. Relatedly, this study explores how caregivers react to a chatbot based on generative artificial intelligence (AI) technology, which provides information and advice on demand and can be accessed anytime anywhere.

AI Applications for Dementia Care

AI (especially natural language processing) refers to a collection of algorithms that gets computers or machines to perform autonomous actions that require human intelligence (eg, understanding complex semantics and intent, reasoning, decision-making, and self-correction). In the field of health care, the advent of AI has led to a wide range of applications, such as behavioral monitoring, risk prediction, screening, triage, diagnosis, rehabilitation, health advice chatbot, robotics, and program planning [11-21]. Such applications may be used to assist or replace human activity, or even to improve performance by enhancing efficiency and reducing human error [22-26]. Thus, AI has the potential to fill some service gaps for families with dementia as societies grapple with this public health crisis.

That said, AI is not without drawbacks. For end users, the greatest concerns are the accuracy of the output and the quality of decision-making [27,28]. An AI program is only as good as the algorithm and the data used to train it. For example, a health risk prediction program in the United States classified Black people as having lower risk profiles, compared with White people with comparable health status, resulting in many Black people being denied the proper service. The reason was due to the algorithm using health care cost as the proxy for how sick the person was, without taking into account the fact that Black people have historically been an underserved population [29].

Two reviews provide valuable insights into the development and use of AI chatbots and technology-driven solutions to support dementia care. Hoel et al [30] explored various technology-driven solutions such as social robots and tablet applications that provide activities or interactions to engage persons with dementia, most of whom live in residential care settings. Although the primary targets were persons with dementia, interactions with family caregivers were found to be enhanced through the involvement of the caregiver in the activity (eg, reminiscence therapy). Through more enjoyable interaction, the level of stress felt by family caregivers might be reduced.

The systematic review by Ruggiano et al [9] focused on chatbots, conversational AI agents that use natural language processing and large language models (both machine learning algorithms) to simulate complex human conversation [31,32]. They found 6 commercially available chatbots designed to assist people with dementia and their caregivers. Focusing on the functions and quality of these tools, their review highlighted the potential of chatbots to offer educational content for caregivers (and memory aids for patients) through accessible platforms like mobile apps and voice-activated devices. These chatbots aimed to provide users with timely information and interactive features to engage people with dementia, but a common drawback was the lack of peer-reviewed, evidence-based educational material, which undermines their trustworthiness. As a matter of fact, none of the chatbots were deployed following empirical user evaluation [9]. The information provided was often not rooted in rigorous scientific research, leaving caregivers unsure about the accuracy and reliability of the advice they receive. Based on limited programmed content, these chatbots inevitably constrain interaction with users and provide advice on a narrow range of questions [9].

Another issue is accessibility. Many chatbots require specific phrases or commands to operate effectively, limiting their flexibility and usability for a diverse range of caregivers. This rigidity can be frustrating, especially for those who are not technologically proficient. Additionally, most specialized chatbots provide only standard answers to preset questions and cannot analyze user intent and emotion. They rely heavily on users to provide specific contextual information for continued engagement.

This Study

In view of the limitations of existing chatbots, this study reports on a newly built chatbot, called PDC30 Chatbot, which serves as a care adviser on dementia caregiving using generative AI technology and an evidence-based, comprehensive knowledge base. By simply providing information and advice, without involvement in decision-making, it avoids potential risks of AI applications mentioned above. At the same time, the use of a

validated knowledge base enhances the quality of the answers and trust among users, with its information extracted by generative AI to produce a new and original response to each caregiver enquiry. As such, this new chatbot offers greater flexibility in input handling, allowing caregivers to engage in natural, conversational interactions without the need for rigid commands. Furthermore, through remarkably improved emotional and cognitive support by virtue of generative AI technology, the chatbot is capable of delivering empathetic responses and practical caregiving strategies without requiring constant caregiver input. This makes it a more autonomous and complete tool for addressing the emotional, cognitive, and practical demands of dementia caregiving.

In the following, we describe in detail the construction of the PDC30 Chatbot and its acceptability from a user perspective. A new chatbot would have little value if there is no evident advantage over other resources. Thus, the chatbot's performance in relation to handling common questions concerning dementia and caregiving was examined by comparing its responses to those of two other chatbots including the popular ChatGPT. Upon establishing its performance value, the PDC30 Chatbot was subject to an assessment of acceptability after a 2-week use by dementia family caregivers.

Methods

Chatbot Development

PDC30 Chatbot

We use the latest GPT-4o large language model by OpenAI [33], with the following prompt to define the personality traits of the chatbot (ie, a personality agent in large language models): You are a professional counselor providing advice on caregivers' emotional issues and caregiving challenges. The knowledge base is the Positive Dementia Caregiving in 30 Days Guidebook, an abridged and updated version of the Benefit-Finding Intervention manual (a psychoeducation program with an emphasis on searching for positive meanings in caregiving) which has been found to reduce caregiver burden and depression, with moderate to large effect sizes, up to 12 months [34-39] (the Benefit-Finding Intervention is a workshop-based program with a lengthy instruction manual written for the trainers. The manual was rewritten in simple language and a more concise form for general public consumption and became the knowledge base for this chatbot). After providing an answer, the chatbot is programmed to reference the source of the ideas, so as to encourage users to do more in-depth reading.

In other words, the chatbot would not answer any question unrelated to dementia and caregiving. As a generative AI chatbot, it can formulate answers to a wide range of questions based on these knowledge bases, rather than simply providing preset answers to selected questions. When irrelevant questions are asked, it would say "Sorry, I cannot answer your question." The chatbot, accessible on any device with internet access (including phone, tablet, or computer), was built on botpress.com, an open-source platform for conversational AI solutions. The chatbot serves as one of the components of a self-guided, automated web-based intervention program called Positive Dementia Caregiving in 30 Days (PDC30), which is undergoing evaluation in a global randomized controlled trial (ClinicalTrials.gov identifier NCT06409455). Hence, we call it the PDC30 Chatbot. Currently, this web-based intervention program, the chatbot included, works only in the English language.

ChatGPT and Chatbot-B as Comparators

To evaluate how well the PDC30 Chatbot works, the same questions (see below) were fed into ChatGPT-4o (as a standard of reference) [33] and another self-constructed chatbot (called Chatbot-B for convenience). As ChatGPT is well-known, we focus on introducing Chatbot-B.

Chatbot-B's design is identical to that of the PDC30 Chatbot, but the reference materials are different. The knowledge base for Chatbot-B consists of (1) 154 caregiving-related web pages by the Alzheimer's Association, (2) 17 dementia caregiving-related web pages by the US National Institute on Aging, (3) 14 caregiving topic-based manuals by the Alzheimer's Society, United Kingdom, (4) World Health Organization's iSupport manual [40], and (5) By Us For Us Guides, a collection of 15 Canada-based documents written by people with dementia and their caregivers [41] (if a document was not optimized for automated processing, its content was manually extracted and saved as a plain text file to improve the chatbot's ability to interpret and analyze the information). In other words, Chatbot-B represents a rather comprehensive and authoritative knowledge base from which answers are drawn. In this sense, Chatbot-B is like an assistant surfing the internet for relevant materials on behalf of the user and summarizes the main points for the user in far less time than the user surfing the internet himself or herself.

Together, ChatGPT and Chatbot-B provide strong reference points for assessing the quality of PDC30 responses. ChatGPT is an existing tool that can be used by caregivers in countries where it is available. It is trained on an enormous text retrieved from the internet but is known to have the risk of providing false information when such information exists on the internet. This reliance on internet-based sources makes it vulnerable to inaccuracies, particularly when it draws from unreliable content. Additionally, the chatbot may struggle with context or nuance, offering responses that are overly general or missing critical domain-specific details, which can be problematic in sensitive caregiving scenarios [9]. Chatbot-B, on the other hand, is a new chatbot dedicated to dementia and caregiving topics using authoritative materials. A caveat needs to be mentioned. There are pros and cons of including many reference materials. Up to a certain point, the benefit of including more texts levels off given the redundancy across their content. Processing time may be lengthened as the knowledge base expands in size. Different texts may also offer advice that contradicts each other. Hence, a chatbot based on a single text (ie, the PDC30 Guidebook) may not necessarily fare worse.

Testing Materials and Chatbot Responses

We constructed 21 questions commonly asked by family members by surfing the internet and subjected the three chatbots to the same questions to see how their answers compare. The

responses provided by PDC30 Chatbot and Chatbot-B are reproduced in Multimedia Appendix 1, whereas those by ChatGPT are shown in Multimedia Appendix 2. Note that due to the use of generative AI, the answers provided to the same question will vary slightly from time to time; thus, these are not fixed answers, but rather one sample of a range of possible answers by the respective chatbot. Moreover, it should be mentioned that the boldfaced headings in front of the bullet points were created by the chatbots; they did not exist in the original sources. Interestingly, at one point, the PDC30 Chatbot addressed the first author ("Dear Tak," response to the question "Why is my wife acting like a different person") and that was the only instance any of the chatbots addressed the user by name when answering questions.

For PDC30 Chatbot and Chatbot-B, one can see that despite using proper nouns (eg, mom and husband) and pronouns (eg, her), the chatbots had no problem understanding they were the care recipients. The wording in some questions was intentionally nonspecific (to mimic everyday conversation) and GPT-4o, when constrained to answer questions related to dementia and caregiving, had no difficulty grasping the meaning in the context of dementia caregiving. On the contrary, ChatGPT expectedly needed information on the specific context to construct more relevant responses (for instance, when asked about preparation for the future, it talked about financial investment unless being told that the question concerned a family having a relative newly diagnosed with dementia). Hence questions for ChatGPT were elaborated accordingly. By comparison, questions posed to PDC30 Chatbot and Chatbot-B mimicked natural conversations a lot more.

In terms of answers, occasionally there are bullet points, the relevance of which to the question is not immediately apparent (eg, Chatbot-B's points "utilize online services" and "stay engaged and active" to the question "What preparation should we make for the future?"). This issue appeared to be more common for ChatGPT, including, but not limited to: considering home safety and daily activities for the preparation for future question; encouraging activity involvement for the question on communication skills; discussing financial or legal planning and communication skills for the question on managing personal feelings and stress; asking the caregiver to join support groups, find respite, consider environmental safety, and to take breaks for himself or herself when the question was how to deal with mom's apathy; and getting adult day care, power of attorney, and medical directives when being asked how to allow husband to wander safely. Such answers may well confuse caregivers, limiting the value of ChatGPT as a consultation resource.

Moreover, ChatGPT responses tended to be repetitive, while missing some key advice to caregivers, such as avoiding confrontation and giving due recognition to the disease as the real causal agent for problematic behaviors. On the whole, the responses by PDC30 Chatbot and Chatbot-B were more concise, specific, and to the point. Considering the fact that these chatbots were providing advice on complicated matters, we think their overall performance was quite good—the results support chatbots using generative AI technology as a viable approach to offer advice to caregivers, and the results are better with topic-focused chatbots. For this reason, we focus on the relative performance of PDC30 Chatbot and Chatbot-B below.

The answers provided by these two chatbots were surprisingly similar. In fact, the answers to the question "I am mad with myself; I made so many mistakes" were identical between the two chatbots, though PDC30's answer was probably clearer with more elaboration. Though there is no straightforward way to ascertain the relative quality of the answers, we are of the opinion that compared with PDC30 Chatbot, Chatbot-B's performance was inferior in relation to the questions "I cannot accept the idea that my Mom has dementia and may leave me one day" and "I am so frustrated I can't control my emotions; I would even take out my irritation on her." One difference between the two chatbots does stand out, which is that when it comes to questions related to emotional or mental health issues (technically the above question about not being able to accept mom's condition is also an emotionally laden question), the PDC30 Chatbot provided a greater variety of suggestions. For example, pleasant event scheduling and alternative thinking are important coping strategies but were mentioned by the PDC30 Chatbot only. Other strategies including positive meaning-making and tackling unrealistic assumptions about the care recipient were also emphasized a lot more by the PDC30 Chatbot. These differences are notable, as psychoeducational interventions that include tactics taken from psychotherapy have been found, in a comprehensive meta-analysis of 131 randomized controlled trials, to be much more beneficial for dementia caregivers (especially in terms of relieving depression and promoting self-efficacy and positive gains) than psychoeducation without such tactics [2]. On the whole, the results support the value of the PDC30 Chatbot as a "counselor" for dementia caregivers. Typically, an answer was provided in 20 seconds or less, despite the volume to be scanned, suggesting that a generative AI chatbot is a rather convenient way for caregivers to obtain basic information and advice.

Some brief remarks about Chatbot-B are warranted before moving on to the main acceptability study. In terms of referencing, Alzheimer's Association materials were used in formulating responses to 14 of the 21 questions; Alzheimer's Society and By Us For Us documents were each used for 12 questions; National Institute on Aging web pages, 9 questions; and iSupport, 8 questions. Thus GPT-4o did scan the entire knowledge input before drafting its answers. Note also that Chatbot-B works only if the URLs are up to date. This can make it a less preferable choice as an intervention tool, compared with the PDC Chatbot which has a stable and well-defined knowledge source.

Acceptability Study for PDC30 Chatbot—Design and Procedure

In light of the positive results for the PDC30 Chatbot, we proceeded to the next phase to evaluate the acceptability of the chatbot. A mixed methods study was conducted, in which caregivers were shown the PDC30 Chatbot's responses to the 21 questions above, and asked to use the chatbot (accessible using a hyperlink) for two weeks, at least once a day (as this study was focused on the evaluation of the chatbot, the other components of the PDC30 intervention were not included). At

the end of 2 weeks, participants indicated, on a self-report questionnaire, their frequency of using the chatbot on a scale of 1=almost never, 2=several times a week but less than daily, 3=once a day, and 4=more than once a day. They rated the chatbot using the following questions: (1) the chatbot is easy to use, (2) the answers are easy to understand, (3) the answers are helpful, (4) overall, you are satisfied with the chatbot, and (5) you would recommend the chatbot to other caregivers (all rated from 1=strongly disagree to 5=strongly agree). Participants were also asked to write down any other thoughts they had about the chatbot; this written feedback was subject to thematic analysis [42].

Participants

Participants were recruited through posting notices on campus. The inclusion criteria are (1) aged 18 years or older, (2) self-identification as providing care to a relative with dementia, and (3) self-reported fluency in English. There was no exclusion criterion. All participants were relatives of students and staff who were taking care of a family member with dementia and who provided informed consent to participate. We stopped recruitment after the 21st participant because data saturation had evidently been reached, as the same themes kept repeating. Participants were not financially compensated but were given continuing access to the PDC30 Chatbot after the study.

Ethical Considerations

The study was approved by the Human Research Ethics Committee of The Education University of Hong Kong (reference 2021-2022-0077). Written informed consent was obtained from all participants.

Data Analysis

The two authors independently read the participants' written feedback to first become familiar with the entire set of qualitative data. After highlighting key points and making notes, they generated initial codes for each written feedback. Themes were then extracted by identifying similar codes and patterns using an inductive approach. The two authors compared their work and found that similar themes were identified. The themes were finalized and articulated [42]. As for the Likert-type questions, data were summarized using descriptive statistics.

Results

Overview

Participant characteristics and their ratings of the chatbot can be found in Table 1. Understandably, participants were predominantly child caregivers (10 daughters and 4 sons). Two caregivers were the daughters-in-law of the care recipient. Only four were spouses (one wife and three husbands) and one was a sister.

As can be seen from Table 1, the responses were overwhelmingly positive. A total of 15 out of 21 (71%) participants used the chatbot more than once per day (overall mean 3.62, SD 0.67). Participants thought the chatbot was very easy to use and most gave the highest rating (mean 4.52, SD 0.68). They also thought the advice provided was quite helpful (mean 4.29, SD 0.56) and relatively easy to understand (mean 3.81, SD 0.98). Given such positive experiences, it is no wonder that they felt rather satisfied with the chatbot (mean 4.05, SD 0.59). A total of 16 out of 21 (76%) participants would recommend or strongly recommend it to other caregivers (mean 4.24, SD 0.83). These ratings were more or less substantiated by the participants' written qualitative feedback (Table 2). Thematic analysis of the written comments revealed 3 recurring themes.

Table 1. Acceptability study sample and their ratings of the PDC30 Chatbot.

Caregiver	Age	Sex	Relationship	Q1[a]	Q2[b]	Q3[c]	Q4[d]	Q5[e]	Q6[f,g]

Mean (SD)	53.62 (11.18)	—[h]	—	3.62 (0.67)	4.52 (0.68)	3.81 (0.98)	4.29 (0.56)	4.05 (0.59)	4.24 (0.83)

[a]Q1: frequency of use.

[b]Q2: whether easy to use.

[c]Q3: answers easy to understand.

[d]Q4: answers helpful.

[e]Q5: satisfaction.

[f]Q6: likelihood to recommend to others.

[g]Except for Q1 which is scored 1-4, all other questions are scored 1-5, with higher scores indicating a better experience.

[h]Not applicable.

Table 2. Participants' written comments (reproduced in full) about the PDC30 Chatbot.

Caregiver	Written comments
A	I love it! I have to work and take care of my mom. My sister do not help. I feel very lonely and not sure what to do at times. Now I can have this chatbot to talk to any time I want - it feels like a friend. And it gives me ideas about how to handle my mom too.
B	Don't feel I should go get help from the centre's social worker again. The chatbot's advise is better! And it works 24 hours a day! I actually feel so stupid now that I never trusted AI. I am really surprised how good it is.
C	The answer refer to a guidebook but we don't have it. That part is a bit confusing. That said, I really like the fact that I can now ask anything any time.
D	Initially I have reservation. I have tried many chatbots (like banks) and they are so annoying because they pretended to help but only gave you standard replies not addressing your query. This one is different. Impressed!
E	I am very busy because my husband fell. So I don't use it much. I appreciate the advise but some suggestions are not easy to follow. But I find it very easy to use. My first thought it is strange talking to a robot. But after using it, I don't feel that anymore. When ok, I will use it more.
F	Can I keep using the chatbot, please? When my nephew mentioned this chatbot to me, I thought it is a joke. Talking to a machine? But I use it every day now. Please let me use it.
G	How come not available earlier? I wish had it 2 years ago when I was most helpless!
H	Did Tom Cruise's boss said drones do not sleep but pilots do? Well, this is a very good drone.
I	This is the first time a chatbot is REALLY answering my questions! There is some wait but waiting time reasonable.
J	Professor, thanks indeed for giving me a chance to use this chatbot. It is very helpful!
K	Most answers are relevant and informative. Quick too. Better than I thought.
L	It say it is not a therapist but it is a therapist. It help me calm down when I was very very frustrated! Thanks. I will try to use it more.
M	A good companion. Answer quality is good. But I use it only when I could not find someone to talk to. It's a backup when no one is available.
N	I can screen cap the answer and send to my husband. Then we discuss how to handle my mother-in-law. I feel more confident because I have both knowledgeable advice and husband support.
O	Frankly, I was very skeptical in the beginning. But I gradually like it more. I have a smart speaker but it does not give good answer to this type of questions.
P	Never used a chatbot. Very interesting. Good information. My wife doesn't know what I do on my phone when I am looking for help. If I call my daughter, she would hear what we said and feel upset.
Q	Some terms are difficult. I need to check dictionary. But very convenient. 24 hour service. My wife has frequent difficult behavior and I like the suggestion to ignore or take a break. Some tips for bathing and serving meal helped.
R	It's a good chatbot. I love it but 2 weeks too short to say how good it really is.
S	Not used to talk to machine. Often I have a problem but forget the chatbot is there. Forget can use my phone. Then afterwards when I see my phone, I remember! Then I ask question and get some helpful answer but sometime too late.
T	I work in IT field and so this is no surprise to me. I am glad something like this is finally available because caregiving is hard! I did not get any nonresponse and response time is very good. The answers are specific with enough elaboration and minimal repetition. These are what determine good user experience.
U	Amazing. It answer all my questions so far. But my father is mild stage. May be my questions not hard enough. Interesting to see if it can help me when things get more tough.

Theme 1: Helpfulness

This is the most dominant theme which was explicitly (caregivers A, B, I, J, L, K, M, N, P, Q, and U) or implicitly (caregivers D, F, G, H, O, R, S, and T) mentioned by 19 (90%) participants. Four (caregivers D, I, O, and T) said the chatbot's answers were appropriate, informative, and specific, unlike other chatbots that provided inadequate, irrelevant, or standardized replies. Caregiver L specifically mentioned that the chatbot helped her to calm down when severely frustrated. Her comments were echoed by caregiver Q who also referred to helpful practical suggestions by the chatbot. Caregiver F, despite being informed at the study's outset, forgot that the chatbot would continue to be available, and asked if she could keep on using it after the testing period, a gesture suggestive of the helpfulness of the chatbot. Another participant (caregiver G), who cared for his wife, lamented the late coming of this resource and imagined what difference it would have made to his situation if it had been available 2 years earlier, again testifying to the perceived helpfulness of the chatbot. By comparing the chatbot to a "very good drone," caregiver H might be saying that the chatbot got the job done (ie, providing good advice), a point verified in a subsequent email conversation with the caregiver. Perhaps a bit exaggerating, caregiver B even complimented the chatbot by saying that its advice was better than the social worker's. One wife caregiver (E), however, thought that some of the suggestions by the chatbot were not easy to follow, which was not entirely surprising as behavioral

and cognitive change takes time and participants did not have the full intervention program to assist them. On the positive side, this comment suggests that the answers were relevant, just not easy to follow through.

Theme 2: Accessibility

In total, 11 (52%) caregivers mentioned, in one way or another, the usability of the chatbot, including being user-friendly (caregiver E), lack of (or low rates of) nonresponse (caregiver T), reasonable waiting time before getting a response (caregivers I, K, and T), and most of all, the chatbot's 24/7 accessibility (caregivers A, B, C, H, and Q). Caregiver H even paraphrased a conversation in the movie "Top Gun: Maverick" to illustrate this point.

Unexpectedly, two caregivers mentioned functional merits unrelated to the chatbot itself. Caregiver N talked about the convenience of saving the chatbot's responses and sharing them with other family members. This action, as alluded to by this caregiver, might encourage more involvement by other family members and support to the main caregiver. In addition, caregiver P made an interesting point about the privacy afforded by using the chatbot on his smartphone. His comment was a reminder of the dilemma faced by many caregivers, especially those in crowded living conditions such as the case in Hong Kong, when trying to seek help when the care recipient is nearby. Conversations, whether over the phone or face-to-face, may be overheard by the care recipient, who, in turn, reacts with more behavior problems. The chatbot operated on the phone offers caregivers private space to get help when necessary.

Theme 3: Attitude Toward AI

Five participants (caregivers B, D, E, F, and O) expressed that they were initially skeptical of AI but the experience changed their perception of it. For example, caregiver B started with a mistrust of AI while caregiver F initially found seeking advice from a machine a ridiculous idea. After trying it, both became excited by the technology and were using the chatbot more than once a day. A related sentiment was expressed by another caregiver, S. She was not used to talking to a machine, and after having access to the chatbot, kept forgetting about it. Yet, the undertone of the feedback was that she found the chatbot responses to be useful and lamented that occasionally she had not taken timely advantage of the resource.

Not everyone was as receptive to the technology. Caregiver M did not reject the chatbot but reserved it for occasions when she could not find people to talk to. Nevertheless, the feedback overall suggested that experience with the chatbot induced a favorable attitude toward it in those who questioned its value to begin with.

Discussion

Principal Findings

This study demonstrates that using a chatbot to help dementia caregivers is a viable approach. Taking advantage of AI development, we were able to build the PDC30 Chatbot that functions as a "counselor" to caregivers (ie, its purpose), by applying a personality agent to constrain the chatbot's behavior and by feeding it with an appropriate knowledge base. The generative AI algorithm summarized the points using "its own" words and organized them using headings to facilitate reading. At first, it might seem that feeding it with more resource materials would help it formulate better responses—for this reason, two other chatbots were included for comparison, namely ChatGPT and Chatbot-B incorporating insider perspectives (those from patients and caregivers) and guidelines by several authoritative agencies. In our testing using 21 common questions by caregivers, there was indeed a tendency for Chatbot-B to generate slightly longer responses than PDC30 Chatbot, though this was not always the case. Nevertheless, length per se does not determine quality, as longer answers may contain irrelevant and repetitive points, as we have seen, especially in the case of ChatGPT. On the whole, we think that PDC30 Chatbot and Chatbot-B were superior to ChatGPT and performed similarly, with PDC30 having a further edge on emotional and mental health issues. In addition, the PDC30 Chatbot was favorably received in an acceptability study of 21 dementia family caregivers after using it more than once a day for two weeks. The chatbot was considered user-friendly, with its responses helpful and easy to understand. Their written feedback about the chatbot centered on three themes: it was helpful and accessible, and it improved their perception of AI as a helping agent. Overall, the experience was rather satisfactory and the participants would strongly recommend it to other caregivers.

Both PDC30 Chatbot and Chatbot-B provide citations of the sources they refer to when formulating responses. A caveat needs to be mentioned. While the citation system may prompt caregivers to do more reading of the relevant materials, it is good only to the extent that the sources can be readily located. As explained in Table 1 footnote, GPT-4o cannot name the author of the web pages cited. If the source is a document, this was handled by the way the document is named, such as "Alzheimer's Society Making Your Home Dementia Friendly"—in other words, the citation is to the name of the file used. If it is just a web page, GPT-4o provides a citation using the first title that appears on the web page; the agency or author producing the web page is omitted—this is primarily due to limitations in GPT-4o's design and functionality. First, GPT-4o cannot read logos or metadata from images on web pages, where authors' names and relevant citation details are often embedded. If the website does not contain alternative text, GPT-4o cannot read the images. Second, while the model processes textual data, it may only effectively distinguish between content and metadata, such as author names or publication details, if explicitly mentioned in the text. The website needs to state the metadata clearly. Additionally, the training data (ie, web page metadata) may not include structured citation formats, making it difficult for the model to recognize and extract authors' names reliably. Furthermore, the design of GPT-4o may include privacy considerations that prevent it from naming individuals unless explicitly included in the training data or provided in a clear, structured format. To address this issue, converting all relevant web pages into text files with clear filenames and structured citation information can help ensure that author names and other citation details are correctly identified and referenced by the model. On the contrary, the PDC30 Chatbot is to be used

together with the Guidebook in actual operation—both are to be hosted on the same intervention website. Thus, the citation problem mentioned above does not apply.

Perhaps a more important consideration in terms of operation is that Chatbot-B requires constant monitoring and updating, should organizations add new web pages, remove certain web pages, or change the URLs of the web pages—there are indeed a very large number of web pages to monitor. Worse, changes to the content of a web page with the same URL will be hard to detect, unless a "last updated date" is provided. By comparison, the PDC30 Chatbot is much easier to maintain, as it is based on only one text.

The PDC30 Chatbot was built with the intention to be included in a randomized controlled trial, and so we subject it to an evaluation of acceptability by caregivers. All but one caregiver provided highly positive feedback about the chatbot; the only exception came from a wife caregiver whose use of the chatbot was disrupted by her husband's fall early in the trial period (had she contacted the research team then, we would have adjusted her trial period so that she would have been able to try the chatbot at a more convenient time. Unfortunately, we were not aware of the issue until she turned in her responses). On the whole, the caregivers found the chatbot easy to use (including the wife caregiver mentioned above) and the answers were informative, relevant to their needs, and easy to understand. Many particularly appreciated the chatbot's helpfulness and 24/7 accessibility, with some further commenting on its lack of nonresponse and reasonable waiting times before responses were generated. As a result, some caregivers acquired a much more favorable attitude toward AI technology because of using the chatbot. The great majority reported high levels of satisfaction with the chatbot and would recommend it to other caregivers. Thus, the PDC30 Chatbot was well-received by caregivers who used it. The chatbot's frequent use was also a testimony to its reception among the caregivers.

Limitations

Despite the encouraging findings, a few limitations need to be mentioned. First, the sample was predominantly adult children. We do not think the paucity of spousal or sibling caregivers was due to the relative lack of digital literacy among older caregivers as there is no skill required to use the chatbot (other than typing questions into the input space). The older, spousal or sibling caregivers who participated generally found the chatbot easy to use. Rather, we think that this reflects cohort differences in the preference for digital material [43]. Furthermore, the composition of the sample is not as one-sided as it seems, as about two-thirds of the caregivers in this community are children [44]. That said, there is no doubt a certain degree of self-selection as not everyone prefers digital resources (we did have two caregivers in the sample who were initially doubtful of the technology). A future study focusing on older caregivers, especially those with little digital literacy, is warranted.

Second, the chatbot was constructed to speak English only, in alignment with the language used in the parent intervention program being evaluated in a global trial. It is probably too harsh to consider this a limitation but in the context of this study, fluent English-speaking persons do not represent the caregiver population in Hong Kong. Due to the time pressure to launch the clinical trial, we also did not recruit caregivers from English-speaking countries. Although the generalizability of the findings may be limited, the PDC30 Chatbot's responses shown in Table 1 suggest that the chatbot should be quite suitable for caregivers in other countries as well.

Conclusions

To the best of our knowledge, this is the first study reporting the development of a psychoeducational chatbot for dementia caregivers and testing its functioning and acceptability among caregivers. The convenience of delivering advice to caregivers by AI-driven chatbots is an approach that needs to be explored further by the field. Services for families with dementia are lacking, especially in resource-poor countries, and even when services are available, many caregivers do not use the services due to lack of time, services not meeting their needs, or simply wanting to locate information themselves [45]. Good chatbots may well fill some of the gaps and get help to these caregivers around the world. There is one more important feature that makes chatbots an advantageous option—only small amounts of data are transmitted each time and hence chatbots are especially suitable for low-income countries and rural areas in general where internet coverage remains an issue.

Acknowledgments

The study was supported by the General Research Fund (18622322) of the Research Grants Council of Hong Kong to the first author. The funder and the sponsor play no roles in conceptual formulation, research design and execution, data acquisition and analysis, and report write-up.

Data Availability

All data generated or analyzed during this study are included in this published article.

Authors' Contributions

STC conceptualized the study and designed the study and the two chatbots. STC and PHFN cosupervised the programmer to set up the chatbots. Both authors contributed to the writing of this manuscript, with STC taking the leadership. Both authors approved the submission and take responsibility for the accuracy and integrity of the work. No professional writer was employed.

Abstract

Background: Many members of Black American communities, faced with the high prevalence of Alzheimer disease and related dementias (ADRD) within their demographic, find themselves taking on the role of informal caregivers. Despite being the primary individuals responsible for the care of individuals with ADRD, these caregivers often lack sufficient knowledge about ADRD-related health literacy and feel ill-prepared for their caregiving responsibilities. Generative AI has become a new promising technological innovation in the health care domain, particularly for improving health literacy; however, some generative AI developments might lead to increased bias and potential harm toward Black American communities. Therefore, rigorous development of generative AI tools to support the Black American community is needed.

Objective: The goal of this study is to test Lola, a multimodal mobile app, which, by relying on generative AI, facilitates access to ADRD-related health information by enabling speech and text as inputs and providing auditory, textual, and visual outputs.

Methods: To test our mobile app, we used the cognitive walk-through methodology, and we recruited 15 informal ADRD caregivers who were older than 50 years and part of the Black American community living within the region. We asked them to perform 3 tasks on the mobile app (ie, searching for an article on brain health, searching for local events, and finally, searching for opportunities to participate in scientific research in their area), then we recorded their opinions and impressions. The main aspects to be evaluated were the mobile app's usability, accessibility, cultural relevance, and adoption.

Results: Our findings highlight the users' need for a system that enables interaction with different modalities, the need for a system that can provide personalized and culturally and contextually relevant information, and the role of community and physical spaces in increasing the use of Lola.

Conclusions: Our study shows that, when designing for Black American older adults, a multimodal interaction with the generative AI system can allow individuals to choose their own interaction way and style based upon their interaction preferences and external constraints. This flexibility of interaction modes can guarantee an inclusive and engaging generative AI experience.

Introduction

Background

Alzheimer disease and related dementias (ADRD) are brain health conditions impacting cognitive abilities such as memory, language, problem-solving, and executive functions [1,2]. Within the United States, older Black American and Black adults have been identified as being twice as likely as individuals from other ethnic groups to develop ADRD over the course of their lifetime [3-5]. In a study conducted with 59,555 individuals, Black American adults had a 65% greater risk of developing ADRD (with 26.6/1000 Black American adults developing ADRD, compared with rates of 19.6/1000 for Latinos, 19.6/1000 for Pacific Islanders, 19.3/1000 for Whites, and 15.2/1000 for Asian Americans) [6].

However, despite being significantly more likely to develop ADRD, Black Americans exhibit lower levels of ADRD-related health literacy compared with other demographic groups [7]. This disparity impacts informal caregivers who often find themselves unprepared and uninformed about ADRD treatment and diagnosis, as well as about ADRD-related sources and help [8]. Therefore, providing essential medical information to these caregivers is crucial in combating the disease.

Considering the potential of new technologies to aid patients and caregivers with understanding medical language by simplifying content and removing jargon [9], generative artificial intelligence (AI) tools, like ChatGPT developed by OpenAI, could offer innovative opportunities in health care, particularly for improving ADRD-related health literacy. Indeed, recent studies proposed using ChatGPT for reliable and comprehensive health information [10-13].

However, relying solely on generative AI to improve underrepresented communities' health literacy can lead to several issues like providing inaccurate or false health information [14,15]. Additionally, studies have shown that using generative AI exclusively for health diagnosis and treatment can reinforce sexist and racial stereotypes and biases [16-18].

For instance, predictive models trained on historical data that lack representation from diverse demographics can reinforce existing biases in diagnosis and treatment plans [19,20]. The exclusion of certain populations in the studies and design process can lead to misdiagnosis and inappropriate treatment [21-23], exacerbating health inequalities rather than reducing them [20,24,25]. Therefore, it is crucial to ensure greater diversity in model training data and include diverse participants in studies and design processes to improve the generalizability of findings [26] and the fit of the technology use for the target population.

Therefore, given the potential of generative AI to improve health literacy and mitigate health inequalities among underrepresented populations, such as the Black American community, it is imperative to design inclusive ADRD health literacy interventions.

Previous studies, especially in the domain of human-centered design, highlight the importance of integrating cultural insights into health care technologies for this community [27-31]. Hence, it is crucial to tailor generative AI–based health interventions to meet the unique needs of Black American informal caregivers of individuals with ADRD.

Thus, this study identified the needs of Black American caregivers of individuals with ADRD by testing Lola, an ADRD-focused generative AI tool. Lola is a multimodal mobile app that provides access to health information from the Alzheimer's Association online repository [1] via text, chatbot, and voice assistant.

Related Work

Generative AI in Health Care

Generative AI has become a transformative force in health care, offering innovative solutions in diagnostics, personalized medicine, and patient care. Recent studies have highlighted the role of generative models in enhancing diagnostic accuracy by analyzing complex medical data and generating synthetic patient data to train other AI systems. For example, a study by Chen and Esmaeilzadeh [32] demonstrated that generative models like generative adversarial networks could significantly improve the detection and diagnosis of diseases by creating high-quality medical images from existing data. Additionally, variational autoencoders have been used to generate realistic medical imaging data, further aiding disease research and model training. Moreover, the use of large language models (LLMs) such as GPT-4 has shown potential for assisting clinicians by generating comprehensive patient histories and suggesting personalized treatment plans [33].

Moreover, the use of LLMs such as generative pretrained transformer (GPT)-4 has shown potential for assisting clinicians by generating comprehensive patient histories and suggesting personalized treatment plans [33]. Studies have also explored the use of LLMs in generating patient education materials and automating routine documentation tasks [34]. Despite still being in its developmental stages, generative AI holds significant promise for enhancing the accessibility of health care [10-13].

Human-Centered Generative AI

Generative AI models are trained on large data sets that may contain biases, further perpetuating stereotypes and disparities in health care [20,24]. More diversity is needed in both data used to train AI models and participants included in studies to ensure the generalizability of findings [26]. Additionally, addressing ethical and regulatory considerations is crucial when deploying AI in health care.

The integration of human-centered design principles into generative AI applications is crucial to ensure these technologies are accessible, intuitive, and beneficial to end users. Research has emphasized the importance of involving end users in the development process to create AI systems that meet their needs

and preferences. For instance, a study explored the application of ChatGPT for developing digital health interventions, finding that user involvement in the design phase led to higher satisfaction and engagement rates among patients [35]. Specifically, user feedback was gathered through focus groups and iterative testing phases, allowing developers to continuously refine the AI user interface and functionality.

Generative AI and the African American and Black Community

Inequalities have been observed in health care and accessibility to these services for underrepresented communities [36-40]. AI systems that initially aim to reduce the disparities in health care also present challenges for health care accessibility for Black American communities.

Addressing the unique health care challenges faced by Black American communities through generative AI is a growing area of interest. It is essential to ensure that these AI systems do not perpetuate existing biases or disparities. Studies have highlighted the potential of generative AI to provide culturally sensitive health care solutions. For example, a study explored the use of mobile health [41] interventions to mitigate the impact of COVID-19 in Black American communities, emphasizing the need for community-specific content and trusted communication channels to improve health outcomes.

Informal Caregivers of Individuals With ADRD and Their Use of Technology

In 2023, approximately 15 million people served as caregivers for individuals with ADRD [1], with African Americans accounting for one-tenth of these caregivers [1]. This unpaid work amounted to an estimated 16 billion hours [1]. Caregivers often feel unprepared for their roles [42], lacking information on diagnosis, treatment, and available resources [8,43].

Technology has been crucial in supporting these caregivers [44], and technologies have been developed to reduce caregiver stress and anxiety [45] and facilitate access to information for caregivers [46]. However, these technologies targeted different demographics than African American and Black populations. For instance, Hong et al [45] developed and tested a technological intervention aimed at reducing the stress and anxiety related with caregiving by focusing exclusively on Chinese participants. On a similar note, Boutilier et al [46] developed and tested a web app to help informal caregivers document information on their ADRD-diagnosed patients and share important changes with the care team. Boutilier et al [46] tested this system with mainly non-Hispanic White participants, with only 1% of participants being Black Americans.

However, no study has focused on Black American caregivers, which is extremely important and challenging at the same time, considering this population's lower level of technology use and adoption [47]. Additionally, a recent systematic review of technological interventions (mainly mobile apps) [48] found that most of these systems did not present any culturally relevant health information and were characterized by low accessibility and low readability.

Previous studies have shown that online health communities (OHCs) offer emotional and instrumental support to caregivers of individuals with ADRD [49] and chronic diseases [50], providing a platform to share experiences and find support from peers [49,51]. Furthermore, only a few technological support interventions for informal caregivers focus on ADRD-related information. Most aim to enhance caregivers' psychological well-being by providing stress management strategies [52] or developing social games to promote physical activity and mutual support networks [53].

We identified 2 gaps in the previous literature. Although OHCs offer instrumental support by sharing caregiving tips, they often lack localized, actionable ADRD information or personalized support tailored to caregivers' and patients' specific needs. Additionally, there is limited representation of Black American caregivers in research, raising concerns about the ability to understand and address their sociocultural background as well as their unique needs compared with other populations, which is vital for developing health technologies for them [49].

Methods

Recruitment

We conducted recruitment and research sessions in close collaboration with a community engagement team who ensured that participants were all caregivers in some capacity for individuals living with ADRD and fulfilled the inclusion criteria. To meet the inclusion criteria, participants had to be older than 50 years, identify as Black Americans, reside in the target area, and actively provide care for a person with ADRD. Throughout this study, emphasis was placed on collaboration with the Black American community within the region. Consequently, 2 community engagement specialists joined the research team to organize monthly community advisory team board meetings to maintain community involvement and awareness of research insights and findings. Prior to implementing any major design decisions, the advisory team board was consulted to ensure cultural relevance. These measures enabled the research team to make more culturally competent decisions.

Ethical Considerations

Ethical approval was provided by the institutional review board at Indiana University (approval number 12241), All participants received a full explanation of the consent procedures, and any specials needs were accommodated during sessions. Participants were compensated with a US $50 gift card for taking part. Participants' privacy and confidentiality were protected by anonymizing the data, changing the wording of the quotes presented in the Results section, and deleting all the audio recordings after the transcriptions were completed.

Data Collection and Analysis

We performed an adapted cognitive walkthrough with users [54,55]. We conducted 15 sessions in 2 regions in the Midwest region of the United States. Each session was completed in a 1-on-1 meeting that involved 1 researcher and 1 notetaker with the participant. Each session lasted approximately 30 minutes. Although we were aware that longer testing sessions might guarantee the collection of more comprehensive feedback, we

made sure to construct the tasks and testing in a way that allowed the emergence of in-depth insights and findings. Moreover, given the older age of our participants, we did not want to induce cognitive fatigue.

During a session, each participant was introduced to the platform and a set of 3 tasks. Those 3 tasks consisted of searching for an article about brain health, searching for ADRD-related local events, and finally, searching for opportunities to participate in scientific research.

As participants performed the tasks, they were asked to voice their thoughts out loud in real time ("think aloud" method [56]), and after each task was complete, there was a brief semistructured discussion centered around 4 tenets: (1) usability (eg, Did you find anything in this task confusing? In what way?), (2) accessibility (eg, How do you expect Lola to answer you? Did you find the information easy to understand? If not, why?), (3) cultural relevance (eg, Did you find the tone of interactions appropriate? If not, how so? How do you think this platform can be made better for the Black American community?), (4) adoption (eg, What do you think would be a good way of spreading knowledge about this so that people you know can properly adopt it and use it?)

Each session was audio-recorded and transcribed. The generated transcripts were spell-checked. Guided by the principles of usability, accessibility, and relevance, 6 researchers coded the transcripts using the open-source software Taguette [57]. The team took an analytical, iterative approach by discussing the codes and consolidating them into themes [58] through second and third rounds of discussion. The resulting major themes about the needs of the users are described in the Results section.

System Design

Overview

Generative AI is at the forefront of technological advancements in health care applications, specifically in the development of interactive tools such as chatbots and voice assistants. In the context of Lola, an innovative app tailored for Black Americans coping with ADRD, generative AI plays a crucial role. It powers both the chatbot and voice assistant, enabling them to deliver intuitive and empathetic user interactions. These AI-driven tools analyze complex user queries, source relevant information, and articulate responses that are both informative and comforting.

Integration With ChatGPT Technology

The core functionalities of Lola—the chatbot and voice assistant—use the natural language processing prowess of ChatGPT 3.5 Turbo.

Voice Assistant and Chatbot Mechanism

These multimodal features enhance the accessibility of the app, providing users with options for both auditory and textual communication. This is particularly beneficial for users with different levels of technological literacy or physical abilities. The real-time response generation capability of ChatGPT ensures that every interaction is smooth and engaging.

Data Utilization and Information Sourcing

Lola's AI systems are designed to draw information from authoritative sources such as the Alzheimer's Association online repository [1], supplemented by curated recommendations from a team of medical doctors specializing in ADRD. This method ensures that the information provided is not only accurate but also up to date with current medical standards and practices.

Ensuring Clear and Meaningful Communication

The generative process involves a sophisticated workflow in which initial responses, structured using LLM techniques, are refined by ChatGPT for clarity and empathy. This ensures that the communication is not only technically accurate but also tailored to meet the emotional and cognitive needs of the users.

Technical Infrastructure

The comprehensive technical infrastructure of Lola uses Flutter for development of the front end to maintain a consistent and engaging user experience with visually appealing, high-performance interactions across various devices and modalities. The back end is powered by Python's Flask framework, paired with a PostgreSQL database for robust data management and fast data retrieval during the human-app interactions. The deployment of Docker for containerization, along with the use of the research team's university servers, provides a secure and reliable environment for hosting and managing Lola's functionalities. By reducing compatibility issues, this setup ensures consistent system performance and reliability.

App Features

In response to the challenges faced by older Black Americans regarding the accessibility of credible ADRD information, Lola's interface serves as a platform for accessing ADRD-related articles, local and virtual events, and opportunities to engage in the latest ADRD research. Lola incorporates a chatbot feature represented by a floating green bubble in the bottom right corner, accessible to users throughout their interaction with the app (Figure 1).

Users can interact with the Lola chatbot by clicking the green call-to-action button, which initiates a conversation through text or voice input. Using generative AI, the Lola chatbot provides responses in text format or as voice messages by clicking the "Play" button, facilitating accessibility for users with varying literacy levels or preferences for voice interaction. Users can also copy the response as text or share the response with their contacts. When users choose to end the conversation, the system saves the conversation in the chat history (Figure 2).

Figure 1. Example of a user having a conversation with the Lola chatbot using the interface designed by the research team.

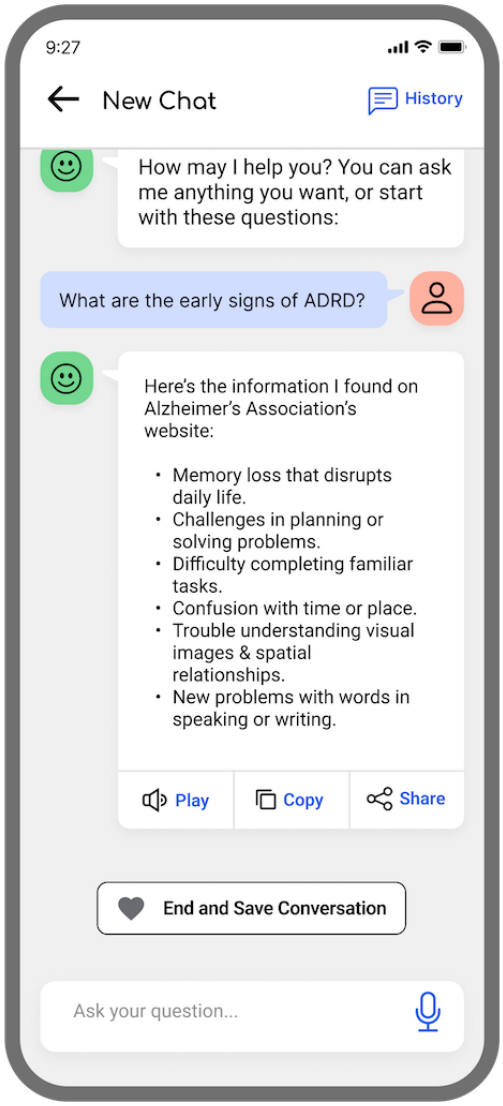

Figure 2. Example of a user using voice input and the possibility of browsing the history.

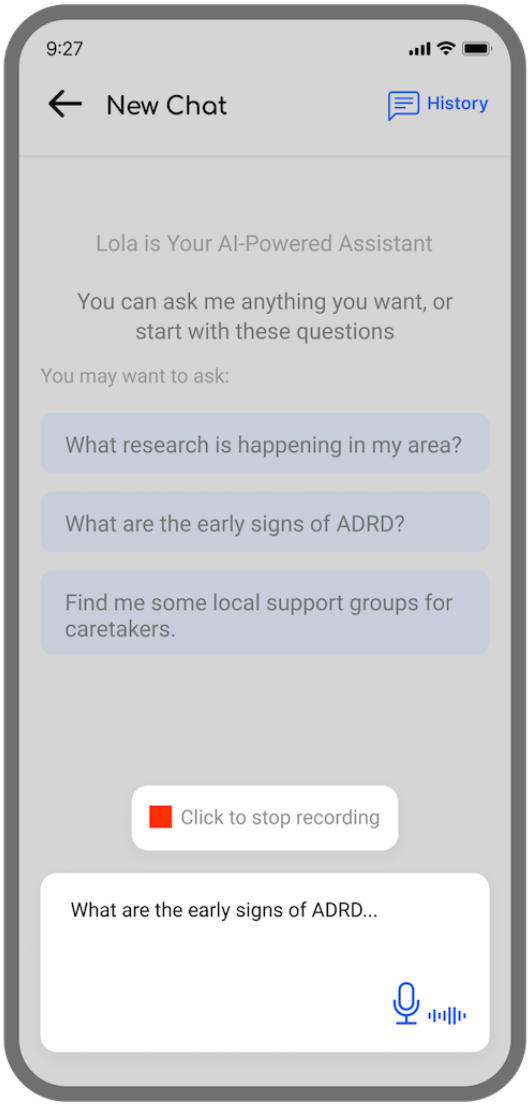

Results

Participant Demographic Information

A total of 15 participants were included in this study. All of them were informal caregivers for someone living with ADRD and were Black American. All participants shared that they were born and raised in the United States. Regarding family origins, 5 participants identified having African family origins, 9 were unsure of their family origins, and 1 chose not to disclose. Table 1 summarizes the participants' demographic data. Of the 15 participants, 12 (80%) were 65 years or older. Most participants were female (11/15, 73%), with 2 (2/15, 13%) being male and 2 (2/15, 13%) providing no gender response. Regarding education, 10 participants (10/15, 67%) indicated having at least some college education (partial completion, a bachelor's degree, or an associate degree), while 2 (2/15, 13%) had a graduate degree, 2 (2/15, 13%) indicated a high school education, and 1 (1/15, 7%) did not provide a response. Most participants (11/15, 73%) were retired, only 3 participants (3/15, 20%) worked either part-time or full-time, and 1 (1/15, 7%) did not respond.

Table 1. Participant demographic information.

Participant number	Age (years)	Gender	Education level	Employment	Work sector
1	72	Female	Some college	Retired	Health care
2	74	Male	Some college	Retired	Utilities
3	68	Female	Associate's degree	Retired	NR[a]
4	69	Male	Some college	Retired	Construction
5	54	Female	Associate's degree	Part-time	Health care
6	66	NR	NR	NR	NR
7	69	Female	Graduate degree	Retired	Community advocacy
8	69	Female	Some college	Retired	Health care
9	75	Female	Some college	Retired	Faith-based
10	71	Female	High school	Retired	Customer service
11	69	Female	Associate's degree	Retired	Insurance
12	72	NR	High school	Retired	Health care
13	68	Female	Some college	Retired	Health care
14	63	Female	Graduate degree	Full-time	Employment specialist
15	62	Female	Bachelor's degree	Part-time	Education

[a]NR: not reported.

Overview of Lola

The Lola system includes 3 different models of interaction: (1) accessing information in a traditional touch screen app format, (2) texting with an AI-powered text-based chatbot, and (3) talking to a voice assistant that accompanies the chatbot. Participants experienced all 3 models of interaction during user testing.

Themes

From the analysis of the data collected, 3 main themes emerged: (1) the need for a multimodal AI tool that relies on multiple senses, (2) the need for culturally specific ADRD content, and (3) the importance of physical places and existing social networks to spread Lola among the community. This section will explore these themes in depth and how they relate to the goals of the research.

Theme 1: The Need for a Multimodal AI Tool That Relies on Different Senses

This theme describes participants' need for interacting with the Lola system in different ways aside from the traditional touch screen gesturing predominant in most mobile apps. This multimodal interaction could take several forms, for example, voice interaction that can read content generated as text out loud. This would allow participants with low vision, which is common among older adults, to access the content.

> *Because with the people that I work with on a daily basis, one is not able to read anymore because she's going blind. So, it's not just Alzheimer's dementia that needs to be looked at, at least all the senses need to be looked at because people are going through so many different things at the same time.* [P4]

Consistently, auditory access to information positively influenced participants' interactions with the system. Some participants preferred to engage with the tool using their voice, hence treating the tool as a voice assistant and asking it questions. For the participants, this was a valuable addition to the traditional touch screen interaction. For people not only with low vision but also with lower digital skills, voice interaction resembles a conversational exchange with which they are familiar and comfortable.

> *I think that this was good to be able to speak it. Because, if you're dealing with people who are not computer savvy or internet savvy, being able to speak it, and it automatically pops up or speaks your question and then being able to close that area so it won't keep recording. That was quick and easy. It was simple.* [P9]

Speaking features (as opposed to just reading and typing information) are especially helpful since they would enable people to access their usual methods of dealing with health-related information, such as writing it down on a piece of paper and saving it for later reference while someone is sharing the information. Having an auditory feature to provide health care information in addition to other interaction models can improve the accessibility of relevant information for those with difficulties accessing digital content due to low visual capacity.

> *That would help too if it played. And then they spoke out the information. And there's different ways I can have a pen and a pad. And then while she's speaking, I could write the information down. Because it is printed small. And you have to read all this information. But if she tells me, and the number you can call is one 800, I'd be writing it down.* [P1]

However, solely relying on the sense of hearing could be a limitation for people with auditory impairments, who could get frustrated by the tool.

> *But I couldn't hear it. I was kind of frustrated. So, it kind of forced me to read it in my eyes are strained.* [P14]

One participant highlighted the benefit of a multimodal approach pairing visual and auditory stimuli together, drawing on their experience in church where reading and listening occur simultaneously.

> *For me and people lazy, they don't want to have to go through the reading it would have, because I would like to hear it while I'm reading it. It is better. If it were just speaking it, I probably wouldn't grasp. But it was speaking in I was reading it and I was falling through. It would have been like being in church. And the preacher is preaching a sermon, he tell you what he coming out of and you fall you open your Bible to that. John 316, and you follow him as he's talking.* [P5]

This theme highlights the importance of creating a system with multimodal interaction and pairing auditory and visual inputs in a way that makes the tool more accessible and allows a broader audience to meaningfully engage.

Theme 2: The Need for Context and Culture-Specific ADRD Content

This theme highlighted the need for contextually and culturally specific mobile apps that integrate relevant and accessible ADRD information. When combined with a multimodal AI tool, these tailored apps can significantly enhance participants' access to the information they need, which is not always directly related to health care.

One participant expressed their discontent with the lack of relevant information in the Lola app, stating that they wanted more than just medical information such as actionable lifestyle changes that can improve their health.

> *Definitely more than just medical information. Because I'm not one to push drugs, I don't take none. If a doctor tells me something is going on, I'm asking first and foremost, what can I do? Or how can you help me get to this process? Naturally? Do I need to implement exercise, do I need to change my diet, what vitamins, whatever. But if they talk about medication, it's gonna be a big turn off for me instantly. So that's just me. Some people think a quick fix is the answer. But every Quick Fix has consequences.* [P4]

Additionally, another participant mentioned the need for accessible ADRD mobile apps. Being able to operate and navigate through the app with little or without outside help is ideal.

> *Well, you know I just had therapy at the hospital, okay. And I was so amazed that every time I went to therapy, they gave me a folder with exercises, and one time they gave me an app. A girl was there, and she showed that to me. And I was just shocked. She used the app to show me the exercises, and every time I went back, she added exercises for me to do on the app. So that was amazing to me. So yeah, the apps are important. They really are. And they're to be simple. And they got to be informative. And they got to be to the point where even the agent can navigate through them.* [P10]

Some participants expressed discontent with the use of language in the Lola app, as it was perceived as too technical and not catering to the target population well enough.

> *Now all these big words, that's what we get me. I wouldn't understand them. Okay, so there's too many words, too many big words, I would not understand.* [P15]

Certain participants expressed a desire for the mobile app to cater to their Black American communities by offering culturally specific ADRD information tailored to their needs. Consequently, they sought additional content that would address their unique concerns and circumstances.

> *So I'm thinking on the other side as the creators of it, maybe you don't want to offend other races or whatever. But if Alzheimer's is more prevalent in my community, I feel like we need to have that target. So we will know exactly where to go, filter through some of the other stuff, some of the things but Alzheimer's and dementia are across the board. But maybe some things are just specific toward my race. Sure. And I want to know that, and I want to know that in the most timely fashion possible.* [P9]

Last, some of the participants highlighted the necessity for the mobile app to include community-centric information and information about local resources and organizations for ADRD, which could be tailored to individual users and their community based on their location.

> *I don't travel too far for it. So, I think there needs to be something located in their community.* [P4]
>
> *More websites because a lot of people are interested in a study of Alzheimer's or dementia. And it's national, local. So, I would rather you know, her give me the local if I had to visit it. It's good to know the national, but also there's local organizations as well.* [P1]

This section showed how providing context and culturally relevant ADRD information that is accessible is requested by the Black American community.

Theme 3: Physical Places and Existing Social Networks Are Necessary to Spread Lola Among the Community

This last theme is related to the importance of using physical community-oriented places and pre-existing social networks to spread technological tools among the Black American community. Our participants suggested community-oriented ways to advertise these health-related technologies to be adopted and used by the community. Most of the participants mentioned the importance of doing demonstrations of the Lola app in physical community places such as a town hall.

> *I think if they're going to implement this process, then they should have maybe a town hall meeting to go through the process have a big screen. The people that are interested in finding out more than they'll do it step by step. So I think that will be a demonstration we're having at a community center or, or even in a building like this, and advertise that we have a new application now called Lola that will help.* [P1]

Finally, participants mentioned how, in the advertisement of the Lola app, it is important to leverage pre-existing social networks within the community, such as relying on word of mouth and showing how people within the community are using Lola.

> *More information to let us know, what makes Lola different from the other? That will make me want to go to Lola more. And that could cover word of mouth, that could cover the internet, having more of these to get people involved to know more, maybe part of the marketing or the draw from my community would be Lola specifically, or is more strategic as far as getting information out to Black communities.* [P9]

This section highlighted how physical locations where the community gathers and existing social networks are vital to promote increased use of Lola, as word-of-mouth marketing is effective when performed by trustworthy individuals.

Discussion

Principal Findings

Deployment of generative AI in the health care domain offers the promise of innovation and expands the potential of equitable health technologies. However, erroneous design and development of generative AI could increase bias and potential harm toward historically marginalized and underserved communities. Including underserved populations in the design and development of a technological intervention has been shown to increase the opportunity for representation and inclusivity [27-31]. Following this line of research, our study investigated the experiences of Black American caregivers using a generative AI tool to seek ADRD-related information (such as symptoms, community resources, financial aid).

This is the first study that specifically addresses the needs, demands, and challenges of this specific population from the perspective of caregivers of individuals with ADRD. An in-depth description of the 3 key design implications to create an inclusive and culturally relevant AI-supported platform for health will follow.

Fostering Inclusivity Through Multimodality

We observed how Black American caregivers expressed the need for multimodality of interaction to equitably access what generative AI tools have to offer. Indeed, they expressed the importance of being able to "talk with the tool" and hear back (eg, read content out loud) in the fashion of a conversational voice assistant. Several participants' insights suggested a preference toward multimedia, emphasizing the auditory and visual senses and providing modes (speaking, reading, and listening) to support these interaction styles. These implications may originate from their day-to-day time constraints, requiring short and efficient interactions.

Previous work addressed the efficiency of using multimodal systems that provide health care. Linders et al [59] created a multimodal health assistant to provide health information. Soubutts et al [60] used a multimodal device to support the needs of households for health and care purposes during COVID-19. The need for multimodal interactions for memory aid systems has been also highlighted [61].

Additionally, multimodality can guarantee a larger audience who will interact with the system [62], thereby allowing people with low vision and low hearing to access the system and seek ADRD health-related information. Within the landscape of designing for inclusive and equitable computing, our study took the approach of multimodal interaction. Our findings emphasize the need to tailor technology to accommodate different interaction styles. This can be achieved by designing multimodal technologies that can meet the needs of differently abled users.

Answering the Call for Context and Culture-Specific ADRD Information

Our findings reflected the caregivers' need for contextually and culturally relevant ADRD information that is specific to their communities or personalized based on their needs and preferences. They indicated their need for lifestyle tips and actionable tools for ADRD rather than only medical information in the system. They also did not want to be offered only general ADRD medical information; rather, they wanted ADRD-related information specific to their community, local resources, and geography. Locality and cultural relevance emerged as 2 of the most important factors influencing the perceived usefulness of the information sought. This is in line with previous studies [63,64] showing that providing community-centered information can increase the acceptance and adoption of generative AI tools. Compared with the use of OHC, which provides general emotional and social support, as identified by previous studies [49-51], our study reveals the need for specialized information on health care. Our participants expressed their need for instrumental and informational support specific to their social and cultural context as well as geographic location. This finding complements the benefits of OHCs to meet all the needs of caregivers including instrumental and information support.

Furthermore, our participants wanted to be sure that the information provided was accessible to people with low literacy skills within their own communities. This is in line with the collectivist nature of African American communities observed in a prior study on technology use [30], wherein, for a technological intervention to be accepted, it must be inclusive of all the members of the Black American community.

Keeping Not Only the People But Also the Community in the Loop

Finally, our study offers a novel contribution in generative AI research investigating how generative AI tools can be advertised and spread among the Black American community. To our knowledge, this is the only study that has investigated this aspect of generative AI use and adoption. Indeed, low technology adoption is a striking problem within Black American

communities, especially among people with low economic status, which prevents them from using online tools to access health information and improve their health literacy [65]. However, low adoption does not arise from the lack of digital tools but also from a skepticism toward digital tools [66]. Privacy is also a crucial concern, as Black American populations tend to be more skeptical toward the use of technology based on a fear of privacy intrusions and breaches of privacy [41,63]; thus, generative AI–based technologies for this population should foster a transparent and reliable way of handling user privacy.

Some studies [35,66-68] have investigated how faith-based organizations can be important for health dissemination and assisting Black American adults seeking health information. Our study expands on these previous studies by exploring the strategies suggested by our participants, which could be used to foster generative AI adoption and its use among their communities.

Hence, although most studies have focused on programs designed to disseminate information based upon the creation of seminars and physical events, our study provides evidence of how physical organizations (faith-based organizations, public as well as medical organizations) could be strategic actors in fostering the adoption and use of a generative AI tool for ADRD. Additionally, given that these populations have limited resources and opportunities to interact with AI systems and often have difficulties accessing any technology (eg, software, hardware, internet) due to financial and infrastructural challenges [39], incorporating these physical organizations is significant. Building trust and familiarity by involving faith-based organizations and communities in the dissemination of the tool, as well as in the tool's use, facilitates not only dissemination but also the ability to break the barrier of skepticism toward health technology, by showing the community how it could embrace the tool.

Finally, ethical implications and concerns must be addressed in the discussion of the findings, even though ethical concerns did not explicitly emerge in this study as its focus was on usability, accessibility, cultural relevance, and adoption. However, it is crucial to discuss how topics such as consent, privacy, and bias can impact the use of generative AI for an underrepresented community. As suggested by previous studies, ethical guidelines committed to social good and human well-being should be developed and followed by AI system developers [32]. Consent and data management must be at the core of every generative AI system, allowing users to be in full control of their own data and their interaction with the tool. Furthermore, it is critical that users who interact with or provide data for AI systems fully understand what they are consenting to. This is especially important for populations with lower literacy rates, for whom the clarity and accessibility of consent forms must be carefully considered.

Limitations

This study is subject to several limitations. First, the sample characteristics are not representative of the broader population. The age range of our participants may not adequately capture the unique challenges faced by younger caregivers who juggle multiple responsibilities alongside caregiving. Future studies should aim to recruit a more diverse sample to better understand the challenges different demographics face in accessing health information for caregiving.

Furthermore, our participants demonstrated a high level of education, with the majority (12/15, 80%) having some college education. This could have influenced our findings, potentially skewing the results toward those with higher educational backgrounds. We recommend future research include Black American individuals with lower literacy levels to better understand their specific needs and how they engage with AI-generated health technologies.

Last, the user experience testing sessions for this study were conducted outside of the participants' daily environments, which may not accurately reflect the day-to-day challenges they might encounter when interacting with Lola. This limitation could restrict the scope of identified problems. Future studies should consider conducting tests in settings and scenarios that more closely mimic real-life conditions to gain deeper insights into the tool's practical efficacy and user engagement.

Apart from the opportunities already identified, our study opens the research space on the intersection between generative AI and underrepresented populations living in the United States. One possibility could be investigating the effectiveness of tailoring ADRD content to the community's values; hence, future studies could quantify the effectiveness of such interventions on user engagement as well as on ADRD-related health literacy. Second, future studies could investigate the impact of different interaction modalities on user engagement, thus understanding whether multimodality is preferred over solely having the opportunity of interacting with one modality, and explore the potential benefit of using different modalities over others in groups with various needs.

Conclusions

This study adds to the expanding field of research focused on deploying generative AI to improve health literacy. More specifically, the emphasis of this study was on improving the ADRD-related health literacy of Black American informal caregivers, who often are solely responsible for individuals with ADRD. Our objective in testing our intervention, Lola, was to identify the specific aspects of our design that need to be tailored and modified. This approach aims to develop a tool that can genuinely assist this population, enhance their ADRD-related health literacy, and support them in their caregiving responsibilities.

Our findings showed that ADRD-specific content should be made contextually and culturally relevant to be perceived as useful by informal caregivers, thereby including information on local, geographically dependent resources. This shows how generative AI designed to improve ADRD-related health literacy should be highly personalized and dependent upon the user's social and cultural context. Additionally, concerning the interactions, relying on multimodality can contribute to creating an accessible tool for informal caregivers, by offering them multiple and diverse interaction strategies. Once again, this

finding indicates the need for a generative AI tool that can adapt to the users' physical and cognitive needs and demands.

Finally, through active collaboration and community engagement, this study provides evidence of the importance of including the users and population of interest in the evaluation of a design as a way to guarantee that generative AI technologies will benefit all individuals within society, even underrepresented communities such as Black American populations.

Abstract

Background: With the increasing number of older adults globally, there is a constant search for new ways to organize health care services. Digital health services are promising and may reduce workload and at the same time improve patient well-being. A certain level of eHealth literacy is needed to be able to use digital health services. However, knowledge of technology readiness in this target group of older adults is unclear.

Objective: The aim of this study was to understand the technology readiness level of a group of older adults who were provided home care services in order to address the present and future needs of this group in relation to the implementation of digital health care services.

Methods: This quantitative cross-sectional study included 149 older adults from Norway receiving home care services. The participants completed the Readiness and Enablement Index for Health Technology (READHY) instrument, assessments of well-being (World Health Organization-Five Well-Being Index [WHO-5]), and assessments of demographic and clinical variables (sex, age, education, living situation, comorbidity, use of digital devices, and use of IT). Cluster analyses were used to group the users according to their technology readiness.

Results: The mean participant age was 78.6 (SD 8.0) years, and 55.7% (83/149) were women. There was good consistency within the assumed READHY scales (Cronbach α=.61-.91). The participants were grouped into 4 clusters, which differed in terms of READHY scores, demographic variables, and the use of IT in daily life. Participants in cluster 1 (n=40) had the highest scores on the READHY scales, were younger, had a larger proportion of men, had higher education, and had better access to digital devices and IT. Participants in cluster 4 (n=16) scored the lowest on eHealth literacy knowledge. Participants in cluster 1 had relatively high levels of eHealth literacy knowledge and were expected to benefit from digital health services, while participants in cluster 4 had the lowest level of eHealth literacy and would not easily be able to start using digital health services.

Conclusions: The technology readiness level varied in our cohort of Norwegian participants receiving home care. Not all elderly people have the eHealth literacy to fully benefit from digital health services. Participants in cluster 4 (n=16) had the lowest scores in the eHealth Literacy Questionnaire scales in the READHY instrument and should be offered nondigital services or would need extensive management support. The demographic differences between the 4 clusters may inform stakeholders about which older people need the most training and support to take advantage of digital health care services.

KEYWORDS

eHealth literacy; digital health services; technology readiness; Readiness and Enablement Index for Health Technology; READHY; chronic conditions

Introduction

In the coming years, the world will have an increasing number of older adults. According to the World Health Organization (WHO), 1 in 6 people in the world will be 60 years or older in 2030 [1]. Today's aging population is more healthy than previous generations, with a longer life expectancy and more years without frailty [2]. Nevertheless, in the future, there will be more older adults with long-term health conditions and frailty [1]. This will further increase the burden on health care services in the coming years. This change in demographics together with a reduced workforce due to a reduction in the birth rate calls for new ways to organize health and care services. There is an urgent need for more efficient ways to provide the needed health care with fewer in-person contacts, the involvement of informal caregivers, an increase in self-management, and a reduction in travel time, particularly in rural areas. Increased digitalization of health care services could be a solution, which could enable and engage more patients, resulting in increased levels of self-efficacy, self-management, and empowerment [3], and thus reduce the burden on the workforce [4]. Moreover, telehealth solutions may increase the number of virtual contacts and provide means for self-monitoring and dialogues with health professionals as an immediate response to the early signs of deterioration in the health condition [5]. The use of telemedicine may be of particular importance in rural areas with scattered settlements, saving travel time and costs for both health personnel and patients. Although evidence for the assumed benefits of the digital transformation of health care services is scarce, particularly among older adults, it will continue in the coming years along with the general digitalization of both private and public services in Norway and many other countries.

In 2021, 96% of Norwegians older than 9 years had access to a smartphone [6]. However, this indicates that 4%, or approximately 200,000 people, do not have a smartphone. A higher number of people probably have an insufficient level of digital health literacy. In a study from 2021, the Norwegian Directorate of Health found that 13% of people aged ≥60 years never used the internet, while 9% used the internet only once a week. Moreover, only 66% of people aged ≥80 years used the internet. Further, 44% of people aged ≥60 years reported no or low experience with digital IDs and 2-factor identification, which are needed to access public web pages [7].

One benefit from the digital health transformation is that citizens and patients may communicate from their homes and receive care and treatment virtually. Services may also be provided by specialists at hospitals in collaboration with registered nurses in municipalities and the person's own general practitioner, offering better coordination. This requires the individuals being cared for to have access to the internet; have devices, such as smartphones, tablets, laptops, and PCs; and have the ability to use these devices. For those not having these resources, it is essential to identify this challenge and plan for the involvement of supporting resources or nondigital services. This calls for new ways to plan for digitally enabled services and usage of digital tools, and to be aware of the specific resources and needs of individuals when offering these.

In this context, awareness of the person's level of digital health literacy [8] and level of technology readiness [9] is important and may be helpful information together with sociodemographic characteristics, including access to and familiarity with digital devices. In particular, older adults have a lower level of digital health literacy, and as lower levels of digital health literacy may be related to economic status, it may be hypothesized that older people living in rural areas with precisely these characteristics may have a low or even insufficient level of digital health literacy. Technology readiness may be a barrier for offering telehealth solutions, which otherwise would be of huge benefit to these people, due to the fact that the remote areas of living may prohibit access to in-person services, particularly outside the summer season. This calls for knowledge about the levels of digital health literacy and technology readiness of different populations.

eHealth literacy, which is currently often used synonymously with digital health literacy, was defined in 2006 by Norman and Skinner as "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem" [8]. Several factors, such as frailty, low level of digital health literacy, and motoric or cognitive impairment, may be barriers for patients when introducing new technologies [10].

One way to identify barriers is by measuring the level of digital health literacy using a multi-faceted instrument such as the eHealth Literacy Questionnaire (eHLQ) [11]. Another way is to expand on the factors necessary for being able to apply digital health literacy in a context, by using the Readiness and Enablement Index for Health Technology (READHY) [9]. The READHY instrument builds on the eHLQ but includes 4 scales related to self-management from the Health Education Impact Questionnaire (heiQ) [12] and 2 scales related to support from the Health Literacy Questionnaire (HLQ) [13]. The READHY instrument has been proven to inform about variations in needs and skills in relation to technology readiness presented as specific clusters.

The READHY instrument can be used both as a framework for qualitative studies [14] and as an instrument to assess the experience of support, elements of self-management, and levels of digital health literacy. It has been used in a number of contexts, such as cancer survivors [15], type 2 diabetes mellitus (T2DM) patients [16], older hospitalized medical patients, and people living with inflammatory bowel disease [17,18]. The separate scales of the READHY instrument have been translated and validated in the Norwegian language, but the complete

READHY instrument has not yet been published in Norwegian research [19,20].

Despite emerging knowledge within various specific conditions, studies focusing on the technology readiness of older adults are lacking. People receiving home care services may have other needs for digital health services than people with specific diseases, such as cancer and T2DM, and it is important to have an instrument that is broad enough to catch these differences. In our study, the READHY instrument will be tested as an option to elucidate the characteristics of this population of older adults living in a rural area.

Data obtained using the READHY instrument can be clustered to identify segments of users, and this segmentation can be enriched with other characteristics, such as sociodemographics, health conditions, and well-being, forming clusters to help health professionals recognize the need for support or training among the people they serve [21]. This information may help health service organizations to plan for subpopulations based on the identified clusters of the general population and with knowledge about the size of particular groups. It may also help health care professionals to have better conversations when introducing new digital health tools or offering telehealth services to ensure meaning and motivation for older adults [22].

The aim of this study was to explore the technology readiness level in a population of older adults living in a rural area, a group that is hypothesized to be less technology ready. Further, the study attempted to examine their digital resources and behaviors and evaluate associations between these factors and their self-reported health and mental well-being, which may influence their motivation and ability to create meaning in using digital health services and tools.

The results of the study may help service providers to better plan for the specific needs of subgroups and provide health care professionals with insights that may help them to better understand how to introduce new digital health tools and services in this group of older adults living in rural areas. This group is more likely to be frail and at the same time may benefit more from virtual and other contacts that are not in-person. Using clustering analysis, we explored the technology readiness level of older adults receiving home care and their characteristics in terms of resources and digital behaviors (ie, sociodemographic variables and use of digital devices).

Methods

Design

This cross-sectional study included 149 older adults recruited from 7 municipalities in South-Eastern Norway. The data were collected by 1 to 2 health care staff in each of the 7 participating municipalities. The same research nurse trained all data collectors (2-hour training session), and the data collectors were supervised by the research nurse during the study period. The participants completed the questionnaires listed below, either self-reported by themselves or in an interview with the health care staff. The participants were approached in a face-to-face setting where they were informed about the study, signed the consent form, and completed the questionnaires.

Population

Health care staff in the municipal home care services and at the lung department of Innlandet Hospital Trust recruited the participants. Patients admitted to the outpatient clinic at the lung department and people receiving home care services from the municipalities were invited to participate in the study. The inclusion criteria were as follows: (1) living at home, (2) ≥65 years of age, (3) receiving home care services, (4) presence of long-term health conditions, (5) fluency in Norwegian, and (6) written informed consent. The exclusion criteria were as follows: (1) severe dementia (Clinical Dementia Rating scale score of 3), (2) terminal disease with <3 months of expected survival, and (3) severe psychiatric disease, including drug abuse. A total of 211 individuals were eligible, of which 62 were not included as they did not consent to participate. Those not included were on average 83.5 (SD 5.7) years old, and 61.3% were female. The process of participant inclusion was from September 2021 to June 2023.

Included Data and Questionnaires

We collected data on age (years), sex (male/female), living situation (alone, with spouse/partner, or with others), comorbidity, education (compulsory lower secondary school, upper secondary education, master's degree, or more than 4 years university), use of digital devices (laptop, PC, tablet, or smartphone), use of technology to access the general physician and electronic medical record, and digital competence (very poor, poor, average, good, or very good).

The READHY instrument consists of 65 items, with 4 scales from the heiQ [12], 2 scales from the HLQ [13], and all scales from the eHLQ (Table 1) [11]. The heiQ is used to assess patient education and self-management and is validated in Norwegian [12,19]. The HLQ is used to assess health literacy and has been translated to and validated in many languages including Norwegian [13,23]. The eHLQ is used to assess the benefits of telemedicine for individuals, evaluate how telehealth services work together, and examine the telemedicine knowledge of individuals [18]. It has been translated, validated, and psychometrically tested in Norwegian [24]. The full READHY instrument is validated in several languages but not yet in Norwegian. The READHY instrument assesses the person's health technology readiness [9]. Each item in the READHY instrument can be scored from 1 to 4 (strongly disagree, disagree, agree, and strongly agree). The scoring of "strongly agree" in the item heiQ8 *emotional distress* is reversed for the statistical analysis, with the highest score representing the lowest level of distress. The scores of the scales in the READHY instrument are calculated as the mean scores of the included items for each scale. The scores of scales with missing data have been included if the number of missing items is ≤50%.

Table 1. Scales from the Health Education Impact Questionnaire (heiQ), Health Literacy Questionnaire (HLQ), and eHealth Literacy Questionnaire (eHLQ) included in the Readiness and Enablement Index for Health Technology (READHY).

Questionnaire and scale	Description
heiQ[a]	
heiQ3	Self-monitoring and insight
heiQ4	Constructive attitudes and approaches
heiQ5	Skill and technique acquisition
heiQ8	Emotional distress
HLQ[b]	
HLQ1	Feeling understood and supported by health care providers
HLQ4	Social support for health
eHLQ[c]	
eHLQ1	Using technology to process health information
eHLQ2	Understanding of health concepts and language
eHLQ3	Ability to actively engage with digital services
eHLQ4	Feeling safe and in control
eHLQ5	Motivated to engage with digital services
eHLQ6	Access to digital services that work
eHLQ7	Digital services that suit individual needs

[a]heiQ: Health Education Impact Questionnaire.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

Cutoff values are not meaningful from a psychometric approach, and the values for scoring in the READHY scales have not been calibrated to each other or to outcomes. Despite this, scores below 2.7 on the scales may mirror that the person has a level of "not being sufficient" as not all items in the scales are scored as "strongly agree" or "agree." A score of 2.0 or lower on the scales may be considered problematic for managing digital health services as most items in the scales are scored as "strongly disagree" or "disagree" [25]. The READHY instrument takes 10 to 20 minutes to complete in most populations (including older adults), but it could take up to 30 minutes to complete for individuals with cognitive impairment.

The World Health Organization-Five Well-Being Index (WHO-5) consists of 5 items. Each item is scored from 0 to 5, where 5 indicates *all the time* and 0 indicates *at no time*. The score of each item is multiplied by 4, giving a total score from 0 to 100.

Some additional questions were asked to enrich the data. A question about digital competence was asked: "If someone knowing you well should assess your IT competence, would they say it is very poor/poor/average/good/very good?" A question about the participants' health was taken from the 36-item Short-Form Survey instrument (SF-36): "In general, would you say your health is excellent/very good/good/fair/poor?" Scores range from 1 (excellent) to 5 (poor) [26], and they were treated as a continuous variable.

Statistical Analysis

The participant characteristics have been presented as means and SDs or frequencies and percentages, as appropriate. The READHY scale score was calculated as the mean of the item scores when fewer than half of the items had missing values. This resulted in 2 excluded cases where the scale score could not be calculated. Ideally, one should start with assessing the dimensionality of the READHY instrument by applying a factor analysis. However, due to convergence problems caused by a very small sample size with respect to the number of items, this approach was not possible. We therefore report the Cronbach α for the scales identified by a previous factor analysis of a Danish dataset [9].

To identify groups of participants based on the READHY scales, we first applied a hierarchical cluster analysis with Euclidean squared distance and Ward linkage to identify the possible number of groups [27]. The results of the hierarchical cluster analysis were then used to determine an appropriate number of clusters in the next step, a k-means cluster analysis [28] with Euclidean similarity measure. By examining the dendrogram from the first step, we expected to gain insights into the natural grouping of data, which would inform the subsequent k-means analysis. In this way, we leveraged the strengths of both methods for more effective clustering and based our conclusion on k-means analysis, which is easier to interpret due to each individual being assigned to one cluster. While choosing the final number of clusters, we considered clinical relevance,

cluster size, small within-cluster variability, and between-cluster heterogeneity.

One-way ANOVA was then applied to assess the differences between the identified clusters with respect to the READHY scales. Further, one-way ANOVA, the chi-square test, and the Fisher exact test were applied to compare the profiles of the identified clusters based on the following variables: all scale scores, age, sex, education (≤12 years or >12 years), living situation (alone, with spouse/partner, or with others), comorbidity (number of chronic diagnoses), use of a laptop, PC, or tablet at least once a week, use of a smartphone at least once a week, use of IT in previous work or studies, use of IT to communicate with public services, use of the Norwegian digital identifier to access a webpage, use of IT to communicate with a general practitioner, logging into a national health webpage, use of IT to find health information on the internet or social media, reading medical journals or test results on a national health webpage, IT competence assessed by others (very poor, poor, average, good, or very good), WHO-5 score, and response to the question "In general, would you say your health is excellent/very good/good/fair/poor?" Pairwise comparisons of groups were performed as post hoc analyses. The results of these post hoc analyses were reported as mean differences and SDs for continuous variables, mean differences and SDs in proportions for dichotomous variables, and effect sizes calculated as absolute values of z-statistics from the Mann-Whitney *U* test divided by the square root of the total sample size for ordinal variables, along with *P* values. Only significant pairwise differences were tabulated.

Two linear regression models were estimated to assess the associations of WHO-5 (primary) and IT competence assessed by others (secondary) with prechosen covariates: age, sex, education (≤12 years or >12 years), living situation (alone, with spouse/partner, or with others), comorbidity, use of a laptop, PC, or tablet at least once a week, use of a smartphone at least once a week, use of IT to communicate with a general practitioner, use of IT to find health information on the internet or social media, reading medical journals or test results on a national health webpage, and response to the question "In general, would you say your health is excellent/very good/good/fair/poor?" The regression models were estimated in cases with no missing values for covariates.

Statistical analyses were performed using STATA version 18 (StataCorp). A *P* value of <.05 was considered statistically significant. No adjustment for multiple testing was applied; however, we separated between ANOVA as the main analysis and post hoc analyses considered purely exploratory. Although we have only reported the results of the post hoc analyses with *P*<.05, we emphasize that all pairwise comparisons were performed. Further, the regression analyses have been considered secondary. Moreover, there is clarity regarding the number of tests performed, allowing the reader to consider the reliability of our findings.

Ethical Considerations

Participation in the study was based on informed written consent. The study was considered by The Regional Committee for Medical and Health Research Ethics in Norway as being outside its jurisdiction. The data collection, data storage, data analysis, and publication of the results were approved by the data protection officer at Innlandet Hospital Trust (number: 14832226). Participants could withdraw from the study at any time and request for their data to be deleted.

Results

The descriptive results of the cohort are presented in Table 2. The mean age of the participants was 78.6 (SD 8.0) years, and 55.7% (83/149) were women. Moreover, 19.2% (27/141) had higher education (>12 years) and 69.8% (104/149) were living alone. The mean scores of the READHY scales ranged from 2.0 (SD 0.5) for the eHLQ1 to 3.1 (SD 0.3) for the heiQ3. The heiQ scales assessed patient education and self-management, and the mean scores for the 4 scales ranged from 2.8 (SD 0.6) to 3.1 (SD 0.3), indicating high levels of patient education and self-management. The HLQ scales assessed health literacy, and the mean scores ranged from 2.9 (SD 0.4) to 3.0 (SD 0.5), indicating a high level of health literacy. The eHLQ scales assessed eHealth literacy, and the mean scores ranged from 2.0 (SD 0.5) to 3.0 (SD 0.3), indicating that eHealth literacy was low in our population. Moreover, the scores differed between the scales. Table 3 presents Cronbach α values for the READHY scales. Except for the eHLQ2 scale with a low Cronbach α of .61, the Cronbach α values ranged from .70 to .91 for the READHY scales, showing good consistency within the assumed scales [29].

Table 2. Summarized statistics of the cohort.

Variable	Value (N=149)
Age (years) (n=148), mean (SD)	78.6 (8.0)
Gender (female), n (%)	83 (55.7)
Education (n=141), n (%)	
≤12 years	114 (80.9)
>12 years	27 (19.2)
Living situation, n (%)	
Living alone	104 (69.8)
Living with spouse/partner/others	45 (30.2)
Number of chronic diagnoses (n=144), mean (SD)	2.6 (1.4)
Use of digital devices at least once a week, n (%)	
PC, laptop, or tablet	72 (48.3)
Smartphone	89 (59.7)
IT to communicate with a general practitioner	34 (22.8)
IT to find health information on the internet or social media	17 (11.6)
Reading medical journals or test results on a national health webpage, n (%)	
Never/rarely	116 (78.4)
Sometimes/always	32 (21.6)
In general, would you say your health is excellent/very good/good/fair/poor, mean (SD)	1.2 (0.8)

[a]heiQ: Health Education Impact Questionnaire.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

Based on visually inspecting a dendrogram from the hierarchical cluster analysis (not presented), exploring 3 to 6 cluster solutions by k-means cluster analysis, and considering clinical relevance, within-cluster variability, between-cluster heterogeneity, and reasonable sample size, the 4-cluster model was chosen (Table 4). The details of patient profiles in the 4 clusters are described in Multimedia Appendix 1. The participants in cluster 1 (n=40) had on average the highest scores on the READHY scales (meaning better eHealth literacy), except the HLQ4 scale. The HLQ4 scale assesses the social support for health, where the scores were intermediate. Participants in cluster 1 were younger than the other participants (P=.006), had a larger proportion of men (P<.001), had higher education (P<.001), had better access to smartphones and PCs, laptops, or tablets (P<.001), had used IT more in their previous work (P<.001), and currently used IT to access health information and stay in touch with the health care system (P<.001). The participants in cluster 3 (n=25) had the lowest average scores on the heiQ4, heiQ5, and heiQ8 scales (patient education and self-management) and the 2 HLQ scales (feeling understood and supported by health care providers, and social support for health). The participants in cluster 4 (n=16) had the lowest average scores on the eHLQ scales (meaning low eHealth literacy knowledge), except the eHLQ4 scale (feeling safe and in control), where their scores were comparable to those of the 3 other clusters. Thus, the feelings of being safe and in control were equal in the 4 clusters. Cluster 2 was the largest (n=66) and had intermediate scores on most of the scales. Interestingly, the question “IT competence assessed by others” differentiated between all clusters, except between cluster 2 and cluster 3 (P<.001).

Table 4. Results of k-means clustering with 4 clusters (n=147).

Scale	Cluster 1 (n=40), mean (SD)	Cluster 2 (n=66), mean (SD)	Cluster 3 (n=25), mean (SD)	Cluster 4 (n=16), mean (SD)	*P* value for ANOVA	*P* value for pairwise comparisons, mean difference (SD) and *P* value

[a]heiQ: Health Education Impact Questionnaire.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

In the bivariate linear regression model, WHO-5 as an outcome (Multimedia Appendix 2) was significantly associated with education and the question “In general, would you say your health is excellent/very good/good/fair/poor?”, while only the latter question remained significant in the multiple model. A 1-point increase in the score of the question “In general, would you say your health is excellent/very good/good/fair/poor?” was associated with a 12.7-point increase in the WHO-5 score.

In the multiple linear regression model with the question “IT competence assessed by others” as an outcome (Multimedia Appendix 3), only “use of a PC, laptop, or tablet at least once in the last week” and “reading medical journals or test results on a national health webpage” were significantly associated with the outcome.

Discussion

Summary of the Main Findings

In this study, we included participants from a rural area in Norway with less education than other parts of Norway, and our recruitment procedure resulted in the inclusion of slightly more women than men. The participants were assessed for technology readiness using the READHY instrument. We found that people receiving home care services in this area had high

levels of patient education and self-management (scores of 2.8-3.1) and high levels of health literacy (scores of 2.9-3.0) but generally low levels of eHealth literacy (scores of 2.0-3.0). The findings were based on the assumption that a score of ≥2.7 (out of a maximum of 4) reflects a sufficient level, as this score reflects overweight of the response "agree" or "strongly agree" to all the items in the scale [25]. The level of eHealth literacy also differed, as scores on the eHLQ scales and between the participants differed, showing less stability than the heiQ and HLQ scales. The eHealth scores were lower in this study than in a previous study by Kayser et al [11], which can be explained by differences in age, education, and study settings. Therefore, in a rural population like the population in our study, the low level of eHealth literacy should be considered when introducing digital health services in the home care setting.

Low eHealth Literacy

The most interesting results for health care services were the characteristics of the participants in cluster 4, with the lowest scores on the eHLQ scales, indicating low eHealth literacy knowledge (Multimedia Appendix 1). These participants were older, were mainly women, and had a lower level of education than participants in cluster 1 (with the highest level of eHealth literacy). Participants in cluster 4 seldom used a PC, laptop, tablet, or smartphone, and they seldom accessed public services generally and health care services specifically compared with participants in cluster 1. The participants in cluster 4 had several diagnoses, although not significantly more than that among participants in cluster 1. We expect their need for care and support from the home care service to be high, and this population group could benefit from digital home monitoring. Nevertheless, the results show that these participants would need more help and facilitation from the health care service than others to take advantage of digital health services. Offering nontechnological services may be a better option. Social resources that could support them in the use of digital health services must be identified if digital health services are offered. If not, they could be discriminated from receiving the same health care services as others.

Screening for eHealth Literacy

We found that the response to the question "If someone knowing you well should assess your IT competence, would they say it is very poor/poor/average/good/very good?" was associated with several variables in the bivariate model, but only the responses to the items "use of PC, laptop, or tablet at least once a week" and "reading medical journals or test results on a national health webpage" remained significant in the multiple model (Multimedia Appendix 3). Surprisingly, no other variables remained significant in the multiple model, but the most likely explanation was the low power in our study. Further, we found a strong association between belonging to 1 of the 4 clusters and the question "If someone knowing you well should assess your IT competence, would they say it is very poor/poor/average/good/very good?" (Multimedia Appendix 1). The answer differentiated between participants in cluster 1 and those in clusters 2, 3, and 4; between participants in cluster 2 and those in cluster 3; and between participants in cluster 3 and those in cluster 4. These associations contribute to the increasing amount of data supporting the relevance and content validity of this single-item scale and indicate that a single question could be used to screen larger populations for the level of digital health skills. Those scoring low on the single question could be further assessed with multidimensional instruments such as the READHY instrument. The READHY instrument consists of 13 scales with a total of 65 items and takes 10 to 20 minutes to complete. It may be exhausting to complete, especially for old frail people with cognitive impairment. Thus, it is preferable if clinicians can scan a population and collect the same information about the technological readiness level using a single question. This single question could potentially help to increase the number of screenings to identify those in need of further investigation. Here, the READHY instrument can be used to identify specific resources and challenges in relation to the use of digitally enabling or assisting services and technologies. However, it is important to emphasize that using 1 screening item will lead to a loss in the understanding of where particular challenges are. Further, we should be aware that it only screens for digital expertise, and self-management and social support are not taken into consideration with this approach.

Well-Being

We analyzed the variables associated with the scores of the WHO-5 (Multimedia Appendix 2). In the bivariate model, there was an association between a higher educational level and higher scores on the WHO-5, which was not significant when adjusting for other variables such as age, sex, living situation, and number of chronic diagnoses. People with a higher level of education had better health, were younger, and had better digital health literacy, which contributed to the loss of the bivariate effect of education on well-being (WHO-5) when adjusting for these variables. Further, we did not find associations of the co-habitant status and number of chronic diagnoses with well-being assessed by the WHO-5. These findings need some consideration, as other European studies have found that living alone is associated with a lower score on the WHO-5 [30-32]. One explanation may be that the context in these studies differs from that in our study (cohort living in a rural area and having long travel distances). The participants in our study were already receiving home care services and thus were in regular contact with a support person and had access to a service they could call, which may be of importance for well-being. The home care service may be equivalent to the effect of living together with others, as people receiving home care services are in regular contact with a support person and have access to a service they can call.

Cluster Profiles

Our analysis resulted in 4 cluster profiles based on the k-means clustering analysis (Table 4). One cluster with high scores in all the READHY scales, 1 with low scores in the eHLQ scales (eHealth literacy), 1 with low scores in the heiQ scales (health education) and the HLQ scales (health literacy), and 1 with intermediate scores. Being male, being younger, having higher education, and having good access to digital devices and knowledge of IT were all associated with a better technology readiness level. This result was comparable to that in a study by Kayser et al [9], which had 1 cluster with the highest scores

in the READHY scales, 1 with low scores in the eHLQ scales, and 2 involving intermediate profiles. In the Danish study by Kayser et al [9], 25% of the participants were in the cluster with the highest READHY scale scores, which is similar to the proportion of 27% in our study. When considering another study [11], comparable proportions of participants were in the group with the lowest eHLQ scale scores (13% in the previous study and 11% in our study). In another Danish study by Thorsen et al [16], it was found that 5 clusters were more meaningful for the population of patients with T2DM. They also described 1 cluster with the highest READHY scale scores and 1 with low scores on the eHLQ scales, with the 3 remaining clusters having intermediate scores [16]. In a study with Danish cancer survivors, individuals in the cluster with the highest READHY scale scores were younger than those in the other clusters [9], as in our study. On the other hand, in the study of Danish patients with T2DM, 1 of the intermediate clusters had the lowest age [16]. A recent Norwegian study recruiting 260 patients from medical and surgical wards found 6 HLQ clusters and 6 eHLQ clusters [33]. They did not collect heiQ data but found that the participants with the lowest HLQ and eHLQ scores had comparable socioeconomic clusters, similar to the participants in cluster 4 in our study [33]. Thus, the 4 profiles based on the k-means clustering analysis of our data are comparable with those in 2 Danish studies and 1 Norwegian study, despite the mean age being higher in our study.

As explained in the statistical analysis subsection in the Methods section, a confirmatory factor analysis to assess the psychometric properties of the READHY instrument was considered. However, it resulted in convergence problems, most likely due to a very small sample size with respect to the number of items. Therefore, we did not succeed in our aim to validate the Norwegian version of the READHY instrument. Instead, we reported the Cronbach α for the scales identified by a previous factor analysis of a Danish dataset [9], which showed good consistency within the assumed scales.

Limitations

The study had several limitations. No formal power calculation was performed prior to the study, and a convenience sample was used. It is suggested that cluster analysis should only be applied when a good group separation is expected, and it is recommended to include a sample size of approximately 20 to 30 individuals per expected group [34]. Based on previous cluster analysis of the READHY instrument [9,16,33], we expected 3 to 5 clusters of individuals in our study. Thus, a sample size of 149 was sufficient according to recommendations. The inclusion of more participants in the study could strengthen our results, could allow us to perform a factor analysis, and might make it possible to report more associations from the regression models (Multimedia Appendix 2 and 3).

The data were collected by 1 to 2 health care staff in each of the 7 participating municipalities. The same research nurse trained all data collectors, and all had experience in assessing and testing the patients. However, we cannot rule out that the use of several data collectors may have caused biases in the data. On the other hand, we used well-established assessment tools that have been found to be reliable and valid. We used a long and extensive case report form (CRF) with several questionnaires. Some of the questionnaires included many questions. The participants may have become tired, especially those with impaired cognitive function, which might have influenced the data quality. The participants were given the opportunity to answer the questionnaires at their own pace and could take breaks if needed. In the end, we found that the data collected were of excellent quality, with limited missing data.

We recruited participants from only 7 municipalities in a rural region in South-Eastern Norway, with a lower education level than that generally in Norway. This fact, in addition to the fact that the participants were recruited from among those receiving home care services, may reduce the generalizability of the study. The READHY instrument should be tested in home care settings in other regions of Norway and in other countries to increase generalizability. The results from future studies and our study could be extrapolated to inform stakeholders in home care services about the need for support when introducing digital health services in their populations. The results may not be generalizable to countries without home care services or with other access to digital devices and IT. On the other hand, the participants in the study represent people who are particularly in need of digital home monitoring because of the travel distances in rural areas, and the results may be important for stakeholders and leaders of health care services in Norway and internationally. Moreover, 62 people did not consent to participate. These people were older and a larger proportion were women when compared with the cohort of participants.

Conclusion

To our knowledge, this is the first study on eHealth literacy in people receiving home care, a population that currently is being offered and in the future will be offered digital technology. Understanding the eHealth literacy knowledge of this population is important to take advantage of digital technology. The technology readiness level varied in the cohort of Norwegian participants receiving home care, and not all people receiving home care services can be expected to benefit from digital health services. Participants in cluster 4 (n=16) had the lowest score in the eHLQ scales in the READHY instrument and should be offered nondigital services or would need extensive management support. The demographic differences between the 4 clusters may inform stakeholders about which older people need the most training and support to be able to take advantage of digital health care services. This study contributes to this important area with information about technology readiness in a population of older adults and with insights into how this is related to their perceived health and digital behaviors. We were not able to report the psychometric properties of the Norwegian version of the READHY instrument, and a larger validation study should be performed.

Abstract

Background: Older patients with serious mental illnesses such as cognitive disorders often rely on family members or spouses (care partners [CPs]) to meet their health care needs. CPs frequently lack essential information to fully understand the patients' illnesses and effectively support their treatment. Open Notes provide patients with digital access to their health care professionals' clinical notes and are associated with many positive outcomes, such as increased adherence and empowerment. However, older patients who use Open Notes may encounter use barriers such as limited digital literacy. Recent developments allow CPs to access Open Notes (proxy access) and receive valuable information, which holds significant potential for improving the care of older patients.

Objective: This study explored the experiences, barriers, and opportunities of older mental health patients and their CPs related to using Open Notes. Furthermore, influencing factors and interdependencies were identified.

Methods: Older patients (n=10) and their CPs (n=10) were provided with web-based proxy access to clinical documentation through a web-based patient portal. In-depth qualitative interviews (N=20) were conducted to explore experiences with this access. Data analysis was conducted in accordance with the constructivist grounded theory approach.

Results: The prerequisites for using Open Notes with proxy access were sufficient digital literacy on the part of the patient or CP, as well as the establishment of a trusting relationship between patients and CPs. Access to Open Notes enabled patients and CPs to gain a deeper understanding of the illness and its treatment while also facilitating enhanced contact with health care professionals. This resulted in greater involvement in the treatment process but may also prompt changes in relationship dynamics—CPs are better equipped to support patients in their health care but may also tend to monitor or control them through Open Notes. As a result, the introduction of Open Notes was accompanied by mixed feelings.

Conclusions: It is of utmost importance to provide older patients with comprehensive access to Open Notes to preserve their health autonomy. However, the involvement of CPs through proxy access is of great value in improving the care of older patients, especially those with cognitive impairments.

Introduction

Background

The ongoing digitalization throughout society, coupled with demographic transformations, presents both opportunities and challenges for the health care sector. The global population is living longer, and in particular in industrialized countries, fertility rates are declining, which is significantly altering the age composition of the population [1]. Concurrently, digitalization is gradually permeating all areas of society, including the mental health care sector, thereby providing patients with new opportunities to participate in their treatments [2]. The European Health Data Space proposal follows this development and aims to improve patients' access and control over their personal electronic health data [3]. One such opportunity for patient participation is through online record access (ORA), which enables patients to view their electronic health records (EHRs) via web-based patient portals. When patients are able to also access their health care professionals' (HCPs) notes via ORA, this is referred to as Open Notes [4-6]. In the United States and some Scandinavian countries, Open Notes are already an established practice in health care [3,7]. Patients in the United Kingdom have the option of accessing the clinical notes of their general practitioners [8]. In contrast, in other countries such as Germany, Open Notes have yet to be integrated into the health care system [9,10]. However, current legislation requires all hospitals in Germany to implement patient portals. Therefore, in the near future, it will be technically possible to offer Open Notes [11]. Access to clinical notes and the associated transparency can enhance patient empowerment and engagement, improve medication adherence, and bolster disease management and awareness [12-15]. Studies indicate that vulnerable groups, including older patients, particularly benefit from Open Notes [16]. Furthermore, it can enhance communication between (older) patients and their HCPs, thereby strengthening trust in the treatment process [17,18]. While many older patients express interest in and intent to use digital health technologies, few actually use them [19]. Because older patients are not considered digital natives, they often face several challenges when using digital health technologies, including limited digital health literacy, usability issues, and heightened concerns about data security [19-21]. In addition, older patients are increasingly affected by cognitive deficits (eg, dementia), which further complicates the development of digital health literacy [22]. These barriers lead to a decrease in the use of web-based health services such as ORA with advancing age, especially without (human) guidance [23]. Therefore, it is imperative that digital health literacy is taken into account in the design of patient portals and EHRs to ensure their accessibility and inclusivity for older users [24,25].

In general, a significant proportion of older patients rely on relatives such as family members, partners, or friends (referred to as care partners [CPs]) to meet their health care needs [24]. This is also true for digital health services [26]. Receiving support from CPs has a positive impact on patients' quality of life, quality of care, and health resource use. In addition, patients and CPs would like to have greater involvement in medical care, but this has not been adequately supported by the health care system [24,27]. CPs often lack essential information about the health status and treatment planning of older patients, which can significantly complicate care [24]. With proxy access, Open Notes allow relatives to read medical treatment documentation with the patient's consent [28]. Giving CPs access to Open Notes provides them with important information and facilitates their care. In addition, studies show that the involvement of CPs can also increase engagement in the treatment of (older) patients using ORA [29]. Current research confirms that such access is desired by CPs [22,30] but acceptance is still limited [26]. ORA and Open Notes will become increasingly important in health care, and the associated opportunities should be available to all patients [22,24]. Therefore, it is essential to gain a deeper understanding of the use patterns of older patients, the role of CPs, and the barriers and opportunities associated with them.

Objectives

To date, only a limited number of studies have examined the use of ORA by older patients in the context of proxy access [24,31,32]. Specifically, in the area of mental health, the authors are currently unaware of any studies on this topic [33,34]. In light of the current state of research, the purpose of this study was to explore the experiences, preferences, and needs of older mental health patients and their CPs, as well as the barriers and opportunities related to using Open Notes. In addition, this study aimed to provide recommendations for best practice in this area and sought to identify the factors influencing the impact of CP access to Open Notes.

Methods

Study Design

The *Piloting and evaluation of a participatory patient-accessible electronic health record for geriatric psychiatric patients and their care partners* (PEP.AGE) study is part of the *Piloting and evaluation of a participatory patient-accessible electronic health record in Psychiatry and Somatics* (PEPPPSY) project (2021-2026) [35,36]. In the PEPPPSY project, patients are provided with access to their HCPs' treatment and progress

notes via a dedicated patient portal [37]. Furthermore, the development and implementation of the patient portal are being examined from the dual perspectives of both patients and HCPs. The PEP.AGE study broadens the scope of the PEPPPSY target population by including not only the perspective of older patients but also that of their CPs. Given the exploratory nature of this study, a qualitative design was chosen to ensure a comprehensive and thorough examination of the use of Open Notes by older patients and their CPs.

Ethical Considerations

This study was approved by the ethics committee of Brandenburg Medical School Theodor Fontane (E-01-20210727) and registered with the German Clinical Trials Register (DRKS00030188). Participants were informed of the study content and procedures both verbally and in writing. Informed written consent was then obtained from all participants. All participants had the right to withdraw from the study at any time without any adverse consequences. All data were anonymized. Participants received a compensation of €40 (US $41.39) for their participation.

PEPPPSY App

The patient portal pilot, called PEPPPSY, was initiated as part of a research collaboration between the Norwegian University of Science and Technology and Brandenburg Medical School Theodor Fontane. The portal was developed through an ongoing iterative and participatory process [35,36]. In addition to accessing clinical notes, patients and CPs can respond to HCPs' entries with comments. HCPs are then notified of these comments and can respond to patients (or CPs) within the same thread. In the current second phase of the project, the pilot has been expanded to include access for CPs (proxy access), which will increase the accessibility and utility of the portal for a broader patient population.

Study Setting

This study was conducted in 2 psychiatric outpatient clinics (Rüdersdorf and Strausberg) of the Immanuel Hospital Rüdersdorf in the state of Brandenburg, Germany. Psychiatric outpatient clinics are specialized facilities that provide psychiatric care to patients with severe mental illness. These patients typically require comprehensive and multidisciplinary psychiatric treatment and often lack access to adequate care in other outpatient settings (such as psychiatric or general medical practices) due to the severity or chronicity of their psychiatric conditions.

Recruitment

Eligible participants were enrolled in the PEP.AGE study from June 2023 to January 2024. Participating patients had to be aged ≥60 years, receive treatment at 1 of the 2 designated sites, and be able to provide informed consent. Patients with risk factors such as self-harm or harm to others and severe cognitive impairment were excluded from the study. Participating CPs had to be adults (aged ≥18 years) and able to provide informed consent.

Data Collection

At enrollment, sociodemographic data were collected from both patients and their CPs. Patients and CPs were then introduced to the use of the patient portal by their HCP or a member of the study team. They were provided with a comprehensive, user-friendly manual and the option of one-on-one assistance to set up their accounts and learn how to use Open Notes step by step. Subsequently, the older patients and their CPs (with patient consent) were given access to the patient portal and the HCPs' clinical notes. At the beginning of the intervention phase, participants were randomly contacted to identify and address any barriers to use. At the end of the 3-month intervention phase, semistructured interviews were conducted with patients and CPs using previously developed interview guides to gain deeper insights into their actual experiences with Open Notes (Multimedia Appendix 1). The interviews lasted between 20 and 30 minutes each. Throughout the study (onboarding phase, intervention phase, and interview phase), the study team kept field notes documenting observations and contextual information [38].

Data Analysis

The qualitative interviews were audio recorded, pseudonymized, transcribed, and analyzed by 2 researchers with the computer-assisted analysis software MAXQDA (VERBI GmbH) using the constructivist grounded theory by Charmaz [39]. The selected analytical approach was appropriate to the research subject as this exploratory study aimed to iteratively develop theoretical concepts from the data. In accordance with the approach by Charmaz [39], the data analysis was conducted continuously, commencing with the earliest data gathering (initial interview). The interviews were initially coded line by line to facilitate the conceptualization of ideas and the development of preliminary codes. Subsequently, focused coding was conducted, whereby the most significant and frequent codes were identified, sorted, and synthesized into overarching categories. Following this, relationships between the categories were identified and connected into coherent theoretical concepts (theoretical coding). On the basis of the developed concepts and emerging theory, the research team returned to the field and gathered additional data on specific themes until theoretical saturation was achieved. For quality assurance purposes, the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist was used (Multimedia Appendix 2).

Results

Sociodemographic Data

A total of 10 patients and 10 CPs were interviewed via telephone (by EMD or MW), and their complete sociodemographic data are shown in Table 1. In total, 5 dyads (each consisting of a patient and their respective CP), as well as 5 independent patients and 5 independent CPs, were interviewed. All participants self-identified as White individuals, were born in Germany, and spoke German as their native language. The age of the patients ranged from 62 to 81 years, with a mean of 71.60 (SD 6.43) years. A total of 70% (7/10) of the patients identified as female, and 30% (3/10) identified as male. Most patients

(8/10, 80%) were retired, whereas a minority (2/10, 20%) were still employed. All CPs (10/10, 100%) were family members of the patients (mainly spouses or children). The ages of the CPs were more diverse, ranging from 45 to 81 (mean 61.20, SD 11.02) years. This was due to the participation of spouses (5/10, 50%), children (4/10, 40%), and other family members (1/10, 10%) of the patients as CPs. In total, 40% (4/10) of the CPs were already retired, whereas 60% (6/10) were still employed part time or full time. Before the start of the PEP.AGE study, the vast majority (8/10, 80%) of the older patients had already given their relatives access to their health information. Patients reported medical discussions with their HCPs to their CPs, shared medical correspondence and medication schedules with them, or were accompanied by CPs to medical appointments.

Table 1. Characteristics of the patient–care partner dyads.

Dyad number	Patients			Care partners		
	Age (y)	Sex	Diagnosis (*ICD-10*[a] code)	Age (y)	Relationship to patient	Employment status
1	67	Female	Mild cognitive disorder (F06.7)	62	Spouse	Part time
2	75	Female	Dementia in Alzheimer disease with late onset (F00.1)	51	Child	Full time
3	80	Male	Dementia in Alzheimer disease with late onset (F00.1)	69	Spouse	Retired
4	81	Female	Severe depressive episode without psychotic symptoms (F32.2)	45	Child	Full time
5	67	Female	Social phobias (F40.1)	69	Spouse	Retired
6[b]	69	Female	Recurrent depressive disorder, current episode severe without psychotic symptoms (F33.2)	52	Child	Retired
7[b]	62	Male	Generalized anxiety disorder (F41.1)	53	Child	Full time
8[b]	68	Male	Recurrent depressive disorder, current episode severe without psychotic symptoms (F33.2)	81	Spouse	Retired
9[b]	78	Female	Bipolar affective disorder, current episode mild or moderate depression (F31.3)	69	Spouse	Retired
10[b]	69	Female	Recurrent depressive disorder, current episode severe without psychotic symptoms (F33.2)	61	Other family member	Full time

[a]ICD-10: International Classification of Diseases, 10th Revision.

[b]No dyad; independent care partners and patients.

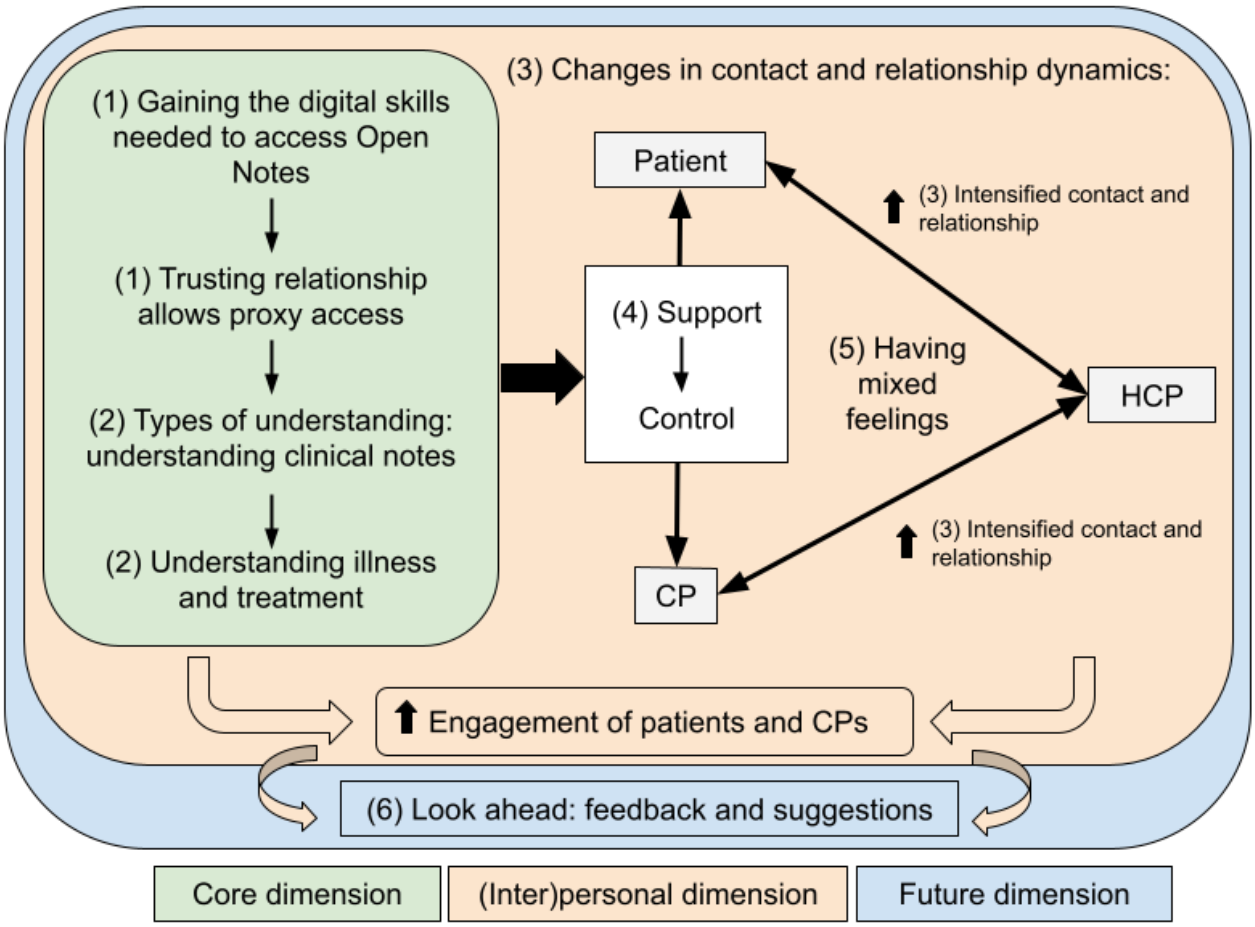
The patients supported by the independent CPs (CPs 6-10) were aged between 71 and 86 (mean 80.8, SD 6.099) years and retired, and they self-identified as White individuals. Patients were being treated for the following main diagnoses: dementia in Alzheimer disease with late onset (*International Classification of Diseases, 10th Revision* [*ICD-10*], code F00.1); mild cognitive disorder (*ICD-10* code F06.7); recurrent depressive disorder, current episode severe without psychotic symptoms (*ICD-10* code F33.2); and mixed anxiety and depressive disorder (*ICD-10* code F41.2).

Qualitative Findings

Overview

The results revealed 3 (partially interrelated) dimensions associated with Open Notes with proxy access when used by older patients and their CPs. These dimensions and their interactions are summarized in Figure 1 and described in detail in the following sections. The green core dimension in Figure 1 provides the foundation for the use of Open Notes and proxy access (eg, digital skills and literacy, trust, and understanding of note content). The red (inter)personal dimension encompasses the impact that Open Notes can have on the relationships among patients, CPs, and HCPs. Finally, the blue future dimension offers ideas and recommendations for the further development of Open Notes. Quotations from CPs and patients are identified using the IDs *CP* and *PAT*, respectively.

Figure 1. Interrelations of the qualitative categories and dimensions related to the use of Open Notes with proxy access by older patients and their care partners (CPs). Arrows pointing upward indicate increase or enhancement. HCP: health care professional.



Gaining the Digital Skills Needed to Access Open Notes

The interviews and field observations revealed that the digital health literacy of the older patients and their CPs varied widely—both between dyads (patient-care-partner pairs) and across participant groups. While some dyads required direct assistance from study team members to activate, log into, and use the patient portal, others required no assistance at all. Younger CPs generally found it much easier to navigate the patient portal than older patients. This variability was also evident in the interviews, with approximately half (4/10, 40%) of the patients and most of the CPs (6/10, 60%) reporting that using Open Notes was challenging or even beyond the digital literacy of the patients, as illustrated by the following statements:

> *It [technical difficulties] could very well be because I'm no longer able to do things like that. [I had] Two strokes and then the nerve disease.* [PAT_0420]

> *New technologies are often a challenge for older people. It takes a lot of patience and support from us younger ones, but it's doable if you stick with it and show them they can do it.* [CP_0213]

As the previous quotes illustrate, a significant number of patients (5/10, 50%) relied on the assistance of their CPs to use the patient portal and Open Notes. At the same time, 20% (2/10) of the CPs themselves indicated that using digital health technologies posed a (manageable) challenge to their digital literacy:

> *I had to overcome a few technical hurdles, but with time and some support, I managed to use the application.* [CP_0213]

The 2-factor authentication log-in process proved to be particularly challenging, if not insurmountable, for some patients and CPs. Some participants were able to overcome this barrier on their own or with assistance (from CPs or the study team). However, others became so frustrated that they stopped using the patient portal altogether. CPs reported the following:

> *Well, there's this two-step login process, where you need the SMS PIN, and then—since I mostly used it on mobile—you have to fiddle around a bit to find where the access to the records is, but ultimately it was okay.* [CP_0209]

> *I had a question once because the access didn't work at the beginning, but it was resolved relatively quickly. They sent me a new one, and I was able to use it. Okay, but I don't know exactly if it was my fault or if it was just issues with the program.* [CP_0409]

Although most participants reported using and perceiving benefits from the patient portal, 30% (3/10) of the CPs and 10% (1/10) of the patients indicated that they did not access the patient portal in their daily lives. This was due to a lack of

perceived need to review the information given their regular contact with the HCP and the absence of a crisis situation that would have made accessing the records more relevant:

> *For us, it [Open Notes] doesn't have any everyday use. The idea that there's the possibility to look up and comment on disputed questions is great. But in the six months we've been participating, there hasn't been a situation that required us to intervene or do anything.* [CP_0211]

Most patients (8/10, 80%) agreed that a solid foundation of trust is a prerequisite for disclosing sensitive clinical information to family members. Some CPs (3/10, 30%) expressed a similar view. An open and honest conversation about the advantages and disadvantages regarding the patients' privacy seemed to be particularly important before using Open Notes with a proxy access, as the following quote shows:

> *We had discussed beforehand what this is and what it means. Otherwise, I don't think she [CP] would have agreed to it. When everything is disclosed, you have to be willing to accept that. Some might say, "Oh no, I don't want that, it's too private," depending on who it is and the relationship involved.* [PAT_0419]

Types of Understanding

Overview

The implementation of Open Notes involves several types of understanding. First, it is essential for patients and CPs to comprehend the content of the clinical note, which requires that the notes be written in patient-friendly language. In addition, by reading the clinical notes, older patients and their CPs were able to gain a better understanding of the illness and its treatment. This allowed them to adequately prepare for medical appointments, reducing anxiety and facilitating understanding during treatment sessions.

Understanding Clinical Notes

Most interviewed patients (8/10, 80%) and half (5/10, 50%) of the CPs agreed that the documentation was particularly understandable when it was composed in a manner accessible to patients without a lot of medical or technical jargon:

> *It [Open Notes] was understandable. Without any medical jargon, everything was fine. The way I described it, he [the HCP] wrote it down, more or less in my own words. It was expressed a bit better, but still in normal, understandable terms, I would say.* [PAT_0411]

> *Yes, it was understandable. Of course, there are always medical terms that might be unfamiliar to a layperson at first. But then you remember the conversation and can figure out what it was about and what was meant. So far, I can't say that I didn't understand anything. It was all very understandable.* [CP_0201]

The previous quotes show that, for some users, the information in the Open Notes alone is not sufficient; rather, understanding is built by combining the knowledge gained from the conversation with HCPs during in-person medical appointments and the information provided in the Open Notes.

Some CPs accompanied patients to their medical appointments and were able to recall the content of the conversations. However, for CPs who were unable to attend appointments, the clinical notes seemed to be easy to understand, as the following quote illustrates:

> *Yes, those were his notes. Brief and to the point. Of course, he didn't write long texts, but at least he documented briefly what was discussed, how the medications are, and what the plan is going forward. He wrote it down in a way that was understandable for everyone.* [CP_0416]

Understanding the Illness and Its Treatment

Some patients (3/10, 30%), but especially CPs (6/10, 60%), reported that access to patient-friendly clinical notes provided them with a more complete understanding and awareness of the patient's illness and treatment:

> *I now have a much better overview of the entire treatment process and my mother's current health condition. This makes it easier to make informed decisions and plan the next steps.* [CP_210]

This improved understanding of the illness appeared to serve as a foundation for subsequent developments, including the increased involvement of CPs in the treatment process and the provision of support. Because treatment appointments often leave little time for questions or repetition, patients (5/10, 50%) and CPs (3/10, 30%) found open-ended notes to be a valuable reminder, allowing them to prepare for and follow up on appointments more easily. Participants found it beneficial to have a written record of what was discussed that they could review at their own pace, allowing them to process the information in a way that best met their individual needs:

> *Remembering and understanding important details and conversation points better. This was especially useful for preparing for appointments and following up on recommendations.* [CP_0213]

> *Because for me, it's easier when I see something in writing, read it, and then respond or share my own experiences. This back-and-forth, this exchange with the doctors and staff, it's easier for me in writing than sitting in front of the doctor who might not have much time.* [PAT_0402]

> *If we have an appointment, we review the last one together, summarize the key points, and build the new medical appointment on that.* [CP_0201]

As the preceding quotes illustrate, one patient noted that reviewing the documentation allowed her to better assess and understand her own treatment progress. Another patient reported that he used the clinical notes to confirm that his HCP had understood him correctly during the visit. This gave him the opportunity to address any potential misunderstandings:

> *Exactly, it allows you to see for yourself that everything was conveyed clearly. When you only attend the doctor's visit and then leave, you forget*

> *half of it anyway. It was much better for me to be able to read it again and confirm that I was truly understood.* [PAT_0204]

Changes in Contact and Relationship Dynamics

Nevertheless, many patients (7/10, 70%) and CPs (5/10, 50%) described Open Notes as facilitating communication with HCPs in a variety of ways. Open Notes, with the opportunity to comment on notes and send messages back and forth, made contact with HCPs faster, more direct, more efficient, more accessible, and more frequent. As a result, participants reported an increased sense of involvement in the treatment process and improved collaboration with HCPs:

> *You can communicate quickly. That is important. It's nice, it's accessible.* [CP_0409]

> *Yes, the contact became more frequent, and I felt more involved in the treatment. It was a very positive effect that improved collaboration.* [CP_0210]

In addition, Open Notes allowed participants to contact HCPs outside of office hours, which was particularly convenient for full-time CPs. All participants were aware that this was asynchronous communication and that responses would only be made during the HCPs' working hours. One patient said the following:

> *You can exchange messages, even on the quick...So having a direct line to the doctor [through Open Notes], without having to call during office hours, is relatively quick. You get a prompt response from the doctor to what you write.* [PAT_0204]

In some cases, communication via Open Notes even replaced telephone contact. This was seen as a relief by some participants (1/10, 10% of patients and 4/10, 40% of CPs) as HCPs were often difficult to reach by phone. In this context, one CP highlighted the portal's communication and commenting function as a valuable tool for patients with mental health conditions who may find phone calls challenging:

> *Interviewer: Okay. And compared to calling, did you feel that you could reach your healthcare provider better or faster through the patient portal than by phone or other means?...Patient: Definitely much better, because calling is always tricky. If they're in treatment, you can't reach them. But this way, they responded when they had time, and everything was handled very quickly, so it was totally fine.* [PAT_0204]

> *As I would say, when patients use it themselves, and I am not a patient, but patients generally have underlying issues, often psychological, which make it difficult for them to communicate. Yes, reaching for the phone is challenging, going to the doctor is difficult. But maybe writing is somewhat less personal and might be easier. And it can be done at night or at an inconvenient time without feeling guilty, so I can imagine this is definitely a good option that could continue to be used.* [CP_0409]

Moreover, a slight shift in the relationship dynamics between patients and their CPs was noted with the implementation of Open Notes with proxy access. Now that CPs had access to the clinical notes, some patients (4/10, 40%) felt that their CPs were more understanding of their mental illness. This suggests a developmental process on the part of the CPs initiated by reading the shared notes:

> *Well, my stepson initially had problems because he couldn't imagine it when I said that it's still hard for me to take the bus alone. I get such a racing heart...But as I said, my stepson couldn't really understand it. Maybe you can't fully understand if you are healthy. But he has learned to understand it.* [PAT_0224]

From Support to Control

There was considerable variability in the level of digital health literacy among the older patients (see the *Gaining the Digital Skills Needed to Access Open Notes* section). In particular, patients in the oldest age group and those with cognitive impairments relied heavily on their CPs to help them navigate the digital patient portal. Some patients delegated responsibility for managing their health information in the portal to their CPs alone, whereas others sought to collaborate with their CPs in reading and understanding clinical notes:

> *My mother is now 82, and at that age, she's not likely to engage with apps or registration issues. If anything, I managed it for her or we discussed it.* [CP_0419]

> *I can open this page and then we can read it together. Or I explain to him what my concerns were. But independently, no longer.* [CP_0201]

In contrast, a younger and more digitally literate patient reported that she was able to access her Open Notes independently and only sought assistance from her CP when she encountered issues:

> *Well, I would first read it [Open Notes] on my own because I only have my daughter as a relative. And she has her own problems at the moment, so I don't really need her help unless I have issues. I'll handle it myself first.* [PAT_0402]

The ability to access clinical notes enabled many CPs (6/10, 60%) to gain a deeper understanding of the illness and treatment of the family member with a severe mental health issue. This increased their confidence in providing effective care and managing the illness, allowing them to better support the treatment (such as preparing for medical appointments and adhering to medication plans):

> *It [Open Notes] significantly improved my understanding. I could better follow the treatment processes and medical decisions. This helped me support my mother better and make informed decisions.* [CP_210]

> *It [Open Notes] was sometimes difficult, especially when the reports were not positive. But it helped me be better prepared and respond quickly if something was wrong.* [CP_0213]

As previously indicated (see the *Changes in Contact and Relationship Dynamics* section), this heightened level of involvement and responsibility, in addition to the improved information flow, was partially attributable to more intensive contact with HCPs, as evidenced by the following quote:

> *Yes, the contact became more intense, and I felt more included in the treatment. It was a very positive effect that improved the collaboration.* [CP_0210]

A few CPs (3/10, 30%) reported that Open Notes enabled them to provide more effective support from a greater distance (eg, from another city or country). Furthermore, CPs observed that reading the clinical notes reduced the need to accompany patients to medical appointments, thereby enhancing autonomy for both CPs and patients:

> *This allowed me to monitor their health data and ensure they received the right care even when I couldn't be with her. It gave me a sense of security to always be informed.* [CP_0210]

In addition to increased involvement, responsibility, and support, some CPs (3/10, 30%) also demonstrated a tendency to monitor or control patients through Open Notes. They compared the patient-reported information from medical appointments with the written information to assess the veracity of the reports and identify any potential omissions. This monitoring held the potential for conflict, but in one case, it also led to a more open and honest exchange between a patient and a CP regarding their inner motivations (eg, the withholding of information due to feelings of embarrassment, fear of disempowerment, or memory issues) and, thereby, enhanced mutual understanding:

> *It [Open Notes] allowed me to access all relevant information and better monitor my mother's health. It helped us be better informed and respond more quickly to changes.* [CP_0210]
>
> *There was a moment of surprise when she didn't mention something or had forgotten, but it was actually helpful because it led to a discussion where I could address it. She was honest, and we could discuss things in more detail or I could suggest she pay more attention to certain aspects. So, it wasn't a bad thing; it facilitated further discussion.* [CP_0416]

Having Mixed Feelings

Both CPs (7/10, 70%) and patients (5/10, 50%) provided insights into their emotional perceptions of the Open Notes. Notably, both patients and CPs reported a similar range of emotional experiences, including both positive and negative feelings. Both groups reported feelings of emotional distress associated with reading about deteriorating health or lack of treatment success. One patient even described experiencing persistent worrying thoughts. Some patients (4/10, 40%) also expressed concern that their CPs might experience distress as a result of reading the notes:

> *Well, it's a bit burdensome, I would say, maybe. When something new comes up and then the success doesn't happen.* [PAT_0402]
>
> *It was a mix of relief and concern. Relief because I was informed, and concern when the information wasn't positive. But overall, it helped me to be better prepared.* [CP_0210]
>
> *I am concerned that my relative may be emotionally distressed by reading the entries [Open Notes].* [PAT_0207]

Both CPs and patients noted that Open Notes provided a sense of security regarding the illness and its treatment. This sense of security was derived from 2 sources: first, the ability to access treatment information and, second, the knowledge that this information has been validated by experts:

> *No, for me it's more like the lack of knowledge is stressful. When you have an informed status, you can handle it better.* [CP_0211]
>
> *Yes, actually good, because I know it comes from a competent source and not just from random internet readings where every third person says something different, and so on. So, for me, it's reliable information. Definitely, knowing without having to worry about whether it's true or not or maybe or something, so that's more reassuring for me.* [PAT_0402]

One patient found it motivating and encouraging to read her HCP's notes. In addition, this patient was particularly motivated by proxy access and the fact that her CP also read the notes, which led her to engage in more self-care. This particular finding suggests that access to clinical notes by CPs may also impact treatment outcomes or patient recovery on a personal level beyond the increased involvement of well-informed CPs in the patients' health management:

> *But when you read the family's comments, like, "Hey, you've been letting yourself go lately," or "You seem unmotivated," it motivates you. You realize they are right; there's no reason to just hang around or whatever.* [PAT_0411]

In contrast, for other patients (2/10, 20%) and CPs (2/10, 20%), the clinical notes were less emotionally significant and were perceived more neutrally, as illustrated by the following quote:

> *You perceive it relatively neutrally. You don't get super happy or deeply depressed.* [PAT_0204]

Looking Ahead: Suggestions and Feedback

Several patients and CPs provided feedback on potential modifications to the patient portal that could improve its usability. Typically, suggestions focused on modifying or enhancing existing features within the portal. For instance, 4 participants (n=3, 30% patients and n=1, 10% CPs) expressed a desire for a read receipt feature to confirm when HCPs had received and read their messages. In addition, 20% (2/10) of the patients proposed that they be notified when a response from their HCP had been submitted. This notification feature had already been incorporated into the system and could be enabled by the user, yet these patients were unaware of its availability:

> *Something like that, just like with emails where you can send a confirmation of receipt or read receipt,*

> *so you know it's been received and opened. Sometimes, that's all you need.* [CP_0416]
>
> *And if the HCP has written something, it would be nice to get an email notification so that I know there's a message there. If it's out of the ordinary and you don't check it every day, you might not see it for a few days.* [PAT_0204]

Moreover, one patient expressed a desire for the portal's features to be more appealing and engaging for older patients, with the goal of tailoring the portal's design to the needs of this patient group (eg, by encouraging them to write comments). Both improved guidance and an optimized design were requested by the participants and could facilitate greater accessibility and appeal for the target audience:

> *A little guidance, maybe. Okay, that we start here, with a specific topic being set. I need to know, what should I write?* [CP_0402]
>
> *But the commenting function should be designed in a way that makes you want to use it, that makes you feel like speaking up.* [PAT_0420]

Other participants expressed a preference for integrating additional features into the patient portal beyond simply reading clinical documentation. In total, 10% (1/10) of the patients and 20% (2/10) of the CPs suggested enriching the patient portal with more psychoeducational information about the illness and integrating some type of psychoeducational lexicon or psychiatric frequently asked questions into the patient portal:

> *And I would certainly wish for a way to learn more about the illness, about behavioral strategies, options for the CP, but also for the patient. So you don't have to Google and look for information elsewhere. If you're already in the psychiatric system, maybe you could listen to more. Do you understand? That on this platform, on this level, you could already have specific questions answered.* [CP_0201]

In fact, one CP expanded the original scope of Open Notes by using the commenting feature to document important developments in her mother's health. She used this primarily as a personal reminder while also indirectly facilitating transparency and understanding of progress for HCPs by posting it on the patient portal:

> *At the beginning, I would write down things that I noticed in my daily life with my mom, as a personal reminder. It was helpful to have these notes ready for the next appointment as preparatory points. I definitely find it useful for that.* [CP_0409]

Discussion

Synthesis of the Findings

The results highlight both opportunities and challenges associated with using Open Notes for older patients and their CPs. In addition, the key drivers of proxy access were identified, and their interdependencies were highlighted. Our results show that older patients and their (sometimes older) CPs must first gain (proxy) access to the patient portal to use and benefit from Open Notes. This requires sufficient digital literacy and mutual trust between patients and CPs. In our study, many older patients needed support from their CPs to navigate digital health services. Once access to open records was established, both parties reported feeling more informed about the illness and its treatment and more in touch with HCPs. These 2 factors led to increased health literacy, engagement, and involvement for both patients and CPs. In line with this, our results suggest that access to Open Notes enables CPs to better support patients in their (digital) health management. However, there was also evidence that CPs used Open Notes to control patients, which could lead to conflicts. Finally, recommendations for further developments and feedback emerged.

Our findings show that it is particularly valuable to allow patients, CPs, and HCPs to digitally engage with Open Notes via a comment function, allowing the stakeholders to directly communicate by sending asynchronous messages. This interactivity of the test environment (*PEPPPSY*) in which our study was conducted was frequently used and highly valued by patients and CPs. In particular, it appeared to contribute to the health literacy of patients and CPs by allowing them to ask questions about the content of the notes or the treatment in general. Communication via Open Notes is not a classic feature of Open Notes, nor is it simply a secure messaging function as the digital interaction is not separate from the Open Note itself. This demonstrates that Open Notes serve multiple purposes (such as providing information, facilitating contact, and offering reassurance) depending on the level of interactivity available [40].

Ensuring Accessibility for Older Patients

As evidenced by previous research and observed in our study as well, older patients (and their CPs) predominantly use Open Notes as a memory aid, benefiting from this tool to prepare for or recap medical appointments. This provides both patients and CPs with an increased sense of security in their treatment processes. The positive effects of the implementation of Open Notes with a proxy access shown in this study—such as enhanced patient empowerment and engagement, increased CP involvement, and improved health management—align with those found in previous research [30,41,42]. Nevertheless, for these advantages to be fully realized, the initial challenge must be addressed: ensuring that older patients and their occasionally also older CPs have convenient access to the patient portal. This seems particularly relevant as older adults show interest in using patient portals yet the existence of numerous barriers hinders their ability to do so [19]. While CPs can indeed play a crucial role in compensating for the patients' lack of digital health literacy—as observed in our study—it is equally important to encourage and enable older patients (with sufficient cognitive abilities) to independently access their health information. Older adults are often apprehensive or skeptical about digital health tools, so addressing these concerns is essential [43]. Furthermore, it is important to ensure that older patients are able to comprehend the content of the Open Notes. Consequently, the clinical documentation must be written in patient-friendly language, which is not always the case in clinical practice [6].

On the basis of the study results, it seems important to provide older patients and their CPs with a clear and detailed explanation of the available features (such as the commenting feature and the opt-in notification feature) before they use the patient portal and Open Notes. It is imperative that patient portal interfaces are designed in a manner that is accessible to all age groups and that the technical requirements are kept as user-friendly as possible. For instance, alternative methods of 2-factor authentication should be explored as requiring users to use 2 devices (eg, a phone and a computer) simultaneously can be overwhelming and frustrating and may, ultimately, result in older patients giving up on using the patient portal and Open Notes. At the same time, increased usability must be compatible with high-level data security requirements. Furthermore, the design of patient portal interfaces should adhere to fundamental age-specific design principles, including the use of appropriate fonts, color choices, and audio alternatives and the minimization of text entry requirements [44]. Providing users with the option to select either a *standard* or *older age–accessible* interface design when accessing the patient portal could prove advantageous as it would enable users to customize their experience to align with their specific requirements. Nevertheless, it seems unlikely that merely modifying the interface will be sufficient to significantly increase the adoption of patient portals and Open Notes among older patients, and therefore, a more comprehensive approach is needed.

First, older patients must be made aware of the availability of patient portals (and the possibility of setting up a proxy access) through comprehensive and targeted informational campaigns [45]. Second, older patients need to be encouraged to use patient portals through the aforementioned campaigns and, more importantly, through their general practitioners and other HCPs [46]. As highlighted in the interviews and supported by findings of other studies, human guidance is essential for older patients to use the full range of features available on patient portals [47]. This responsibility should not be borne solely by CPs, particularly given that not all older patients have access to a digitally literate CP [48].

In light of the ongoing digitalization of the health care system, it may be worthwhile to consider the introduction of an institutionalized role dedicated to this task. In the United States, the role of digital navigator is currently being investigated and defined [49]. Digital navigators are HCPs who have undergone specialized training in the area of digital mental health applications. They provide consultative assistance to health care providers and offer continuous guidance to patients in using these applications [50]. To date, this role has been primarily concerned with the use of digital health applications. However, in light of the increasing international adoption and promotion of EHRs and ORA, it may be beneficial to consider expanding the role of digital navigators to encompass these additional tools and consider the integration of artificial intelligence–assisted support—as proposed by Wunderlich et al [48] with the concept of digital case managers. Nevertheless, artificial intelligence solutions should not replace human guidance as one of the primary concerns of older patients is that digital services could potentially supplant personal contact with HCPs [43].

Preserving the Autonomy of Older Patients

In addition to the aforementioned fundamental requirements for adapting patient portals to ensure accessibility for older adults, other aspects must be considered when involving CPs through proxy access. In the course of our study, the themes of trust, support, and control emerged as particularly salient, a finding that is also corroborated by other studies [30]. Despite the fact that CPs are only granted proxy access with the informed consent of the older patients, there is a risk that they may use Open Notes as a tool for control. This issue has significant ethical and practical implications [51]. Patients with dementia are especially reliant on the assistance of CPs in the management of their health [52], which also applies to the use of digital patient portals [53,54]. It could be argued that, particularly in cases in which patients are experiencing significant cognitive decline, such as with dementia, a certain level of control may be necessary and appropriate within the context of their care. Moreover, all participating older patients consented to the involvement of their relatives (and may revoke this consent at any time), thereby indicating their general assent to the sharing of information (and, thus, also to the potential for control). Nevertheless, this controlling behavior represents a substantial limitation of the patients' autonomy and may potentially give rise to conflict in the relationship between patients and CPs. Furthermore, in accordance with the systemic *concept of a good reason*, it can be assumed that all behaviors, including the deliberate withholding of information by patients, are motivated by a good inner reason and represent a more or less constructive coping mechanism in the face of challenges and difficulties (eg, to avoid shame or to maintain independence) [55].

At this point, it is pertinent to re-examine whether these considerations are applicable to patients with age-related cognitive impairments. These reflections could likely be extended indefinitely, leading to a vicious circle. However, it is possible to diverge from this loop and conclude that it is essential to preserve the dignity of older patients (with and without dementia) while using ORA and Open Notes [56]. Therefore, it is crucial to consider how the experience of (controlling and) being controlled can develop into a trusting dependence on the support of CPs [57]. Caine et al [58] and Latulipe et al [30] suggest that patients should be informed precisely about which information CPs can access in the patient portal. It seems particularly important to provide patients with the option of fine-grained access settings, allowing them to decide which information should be shared and which should not [59]. Such fine-grained functionality was available in early versions of the Swedish national patient portal [3,60]. In addition, a *break-glass* access control protocol can be implemented whereby patients can define which information should be released in an emergency (eg, in the event of a significant deterioration in cognitive health or an unexpected hospitalization) [30,61]. Careful attention must be paid to defining the end points meticulously and distinctly (eg, establishing clear criteria for what constitutes significant cognitive decline).

Implications

Older patients can benefit significantly from Open Notes with proxy access in their health care. However, to realize these benefits, older patients (and their CPs) must first be empowered to access the patient portal and understand clinical documentation. This requires adapting the design of patient portals to the needs of the older patient population and supporting the digital literacy of older patients through tailored individual and structural interventions. Enabling patients and CPs to interact with their HCPs through Open Notes seems to be a particularly important new feature. Many older patients rely on the support of CPs to manage their health care, especially when using digital health services. However, to ensure that older patients maintain their autonomy and dignity when using digital health services such as Open Notes, it is crucial to prevent these tools from becoming instruments of control for CPs. Older patients should be able to make granular decisions about what information they want to share with their CPs and what they want to keep private. For emergencies, a *break-glass* access protocol should be established in advance.

Limitations

This study was based on a small number of participants, which limits the generalizability of the results. Furthermore, the group of participants was highly homogeneous with regard to the categories of race and migration status. To obtain generalizable results, larger studies with a more diverse selection of participants are required in the future. Similarly, older patients and their CPs represent a relatively specific participant group, which further limits the generalizability of the results. Younger patients and their CPs (eg, children or adolescents) may have differing user experiences and encounter completely different barriers and opportunities while using Open Notes. It is also necessary to consider the potential influence of social desirability bias. It can be assumed that older patients might have occasionally embellished their statements regarding their own digital literacy and the usability of the patient portal. For instance, a greater number of CPs than patients indicated that the patients experienced difficulties when using the portal. It is difficult to acknowledge one's own shortcomings and limitations. Furthermore, it is particularly challenging to do so in the presence of others, such as CPs and interviewers, as this could lead to embarrassment and perceived loss of status. It should also be noted that the interviews were conducted via telephone. Although the participants were asked to find a quiet and secure place, it cannot be guaranteed that they were undisturbed throughout the interview. However, the telephone interviews allowed the older patients to remain in their homes (ie, they did not have to travel long distances) and have quick access to support from their CPs in case of difficulties (eg, technical problems or comprehension problems due to cognitive deficits). Thus, telephone interviews allowed older patients with physical or cognitive impairments, as well as CPs living in other cities or countries, to take part in the study and reduced barriers to study participation.

Conclusions

Our study suggests that access to Open Notes can facilitate understanding and engagement between patients and their CPs and is associated with improved communication with HCPs. This may influence the dynamics of the triadic relationship among patients, CPs, and HCPs, with potential implications for power dynamics. In summary, no single patient portal can be expected to meet the needs of all patients—one size does not fit all. Individual solutions and adaptations of ORA are clearly needed to ensure acceptance and meaningful use by older patients and their HCPs.

Acknowledgments

This study was funded by the Brandenburg Medical School Theodor Fontane publication fund supported by the Ministry of Science, Research, and Culture of the State of Brandenburg.

Authors' Contributions

All authors contributed to planning, analysis, and the critical interpretation of the findings. JS and EMD contributed to the study design, and JS supervised the study. EMD and MW contributed to data collection. EMD conducted the data analysis. EMD wrote the first draft of the manuscript. EMD, VD, and JS modified successive drafts. JS edited and approved the final version.

Abstract

Background: Caregiver-friendly workplace policies (CFWPs) are rare in Hong Kong. With Hong Kong facing a "silver tsunami" in the near future, it is important to understand the need for such policies and the views of employers for future facilitation.

Objective: This study aimed to identify the support that is currently provided or that could be provided to caregiver-employees (CEs) caring for older adults in Hong Kong and assess the challenge and facilitative support for employers to adopt CFWPs in the specific context of Hong Kong.

Methods: A qualitative research design with semistructured individual in-depth interviews with employers from Hong Kong was adopted for this study. A purposive snowball sampling method was used to recruit participants from the 7 primary industries mentioned in the Hong Kong census and from all 3 employer types (private, public, and nongovernmental organizations), which allowed the inclusion of participants sensitized to the idea and potential of CFWPs. Thematic framework analysis was used to evaluate the data collected during the interviews.

Results: We interviewed 17 employers and managers from 7 major industries in Hong Kong (2.5 to 120,000 employees). There were 4 (24%) male and 13 (76%) female participants, and the participant age ranged from 30 to 50 years. All participants held managerial positions at the time of the interview. Of the 17 participants, 13 were from private companies, 2 were from public institutions, and 2 were from nongovernmental organizations. Four of the companies had a global presence. Four main themes were identified: (1) current support and potential support for CEs (which was limited to discretionary annual leave and unpaid leave when annual leave was exhausted), (2) challenges in adopting CFWPs, (3) facilitating support for adopting CFWPs, and (4) incentives for adopting CFWPs. The participants rated information and resources for CEs (mean 8.56, SD 0.37), bereavement leave (mean 8.47, SD 0.63), flexible working hours (mean 8.32, SD 0.48), and caregiver-inclusive corporate culture (mean 8.32, SD 0.48) as essential CFWPs for CEs in Hong Kong.

Conclusions: While several studies have reported the types of CFWPs and their impacts on CEs, stakeholders' perspectives on CFWPs have been rarely investigated. This study found that although employers consider CFWPs as necessary and see them as a catalyst for a long-term win-win situation, the current support for CEs is discretionary and industry-specific. Government leadership is critical for formulating, piloting, and implementing CFWPs to create a friendly environment that encourages disclosure with trust and respect across industrial sectors in Hong Kong. This study identified the current unmet needs and demands of CEs

from the employer's perspective, the barriers to large-scale adoption of CFWPs, and the path forward to inform further discourse and policy formulation in Hong Kong.

Introduction

Filial piety has strong cultural roots in Confucian ideology and is especially prominent in Eastern countries in contrast to children-centered societies, which are more prevalent in Western countries [1-3]. However, there is some evidence of the reduction of the influence of classical Confucian ethos in Asian societies, especially in highly urbanized cities like Beijing [4,5], although the extent of this change is currently unknown. Similarly, the cultural reconfiguration of familial values and expectations has been noted among immigrant Asian families in Western countries [6].

Moreover, emerging research indicates that authoritarian filial piety, which prioritizes social obligations toward parents over one's own needs, varies, but reciprocal filial piety, characterized by genuine gratitude for parents' efforts or sacrifices and voluntary support for them, remains consistent across Eastern and Western cultures [3,7,8]. For instance, a study comparing filial piety among Asian Singaporean and non-Asian Australian adults showed a significantly higher mean score for authoritarian filial piety (mean 21.6, SD 5.9 vs mean 19.4, SD 6.0) on the standardized dual filial piety scale among Singaporean adults, but reciprocal filial piety (mean 34.4, SD 4.8 vs mean 34.2, SD 4.4) was comparable in the 2 populations [8].

Important differences have also been noted in patterns of filial piety within Asian cultures. For example, young adults in Taiwan endorsed strong beliefs in reciprocal and authoritarian filial piety, with both beliefs positively impacting life satisfaction, while young adults in Macau endorsed strong beliefs in reciprocal filial piety and those in Hong Kong endorsed strong beliefs in authoritarian filial piety, with positive impacts on life satisfaction [9]. Interestingly, collectivism and not ethnicity has been identified as a predictor of both forms of filial piety and positive attitudes toward caring for aging parents [7]. Hence, filial piety may be more cross-cultural than previously believed, albeit with regional nuances [7,8]. Indeed, 74% of older adults in the United States National Health and Aging Trends Study (NHATS 2011-2017) reported receiving support from one child caregiver, and 41% of children provided care to aging parents [10].

The rapid increase in the aging population has also increased the caregiving burden of family caregivers, with both being reported across cultures and countries [11,12]. Although several studies have identified caregiver burden as a significant risk factor for burnout and poor mental health outcomes among family caregivers [11,13,14], stronger filial piety may lead to lower caregiver burden [15,16]. A systematic review of 12 studies showed a significant negative correlation (r=–0.23) and association (β=–0.27) between filial piety and caregiver burden among adult children [15]. However, although filial piety is a prominent determinant of caregiver burden, it is not the sole determinant even in Asian societies [17].

While noting mild-to-moderate burden among Asian caregivers of older adults with chronic illnesses, a systematic review observed that specific characteristics of the care recipients (functional dependency, comorbidities, memory, and sleep impairments) and caregivers (advancing age, male gender, spouse as a care recipient, longer care duration, and lack of support/assistance) were associated with higher caregiver burden [16]. However, Asia has a lower old age dependency ratio (population aged ≥65 years to working age population) and health-adjusted dependency ratio (population with the same or higher disease burden to population with a lower disease burden as an average global 65-year-old person) than Europe, North America, or Oceania [18].

East Asia, in particular, has the highest employment-to-population ratio globally (63; for comparison, the corresponding numbers for the Euro area and North America are 58 and 60, respectively) [19], and thus, a substantially large proportion of caregivers in this region likely have a dual role of carer-employee (CE). Studies have shown that those with elderly or child caregiving responsibilities are less favorably viewed by employers in terms of competency (F_2=10.99; P<.001; η^2p=0.092), agency (F_2=15.00; P<.001; η^2p=0.121), commitment (F_2=164.83; P<.001; η^2p=0.602), and availability (F_2=69.01; P<.001; η^2p=0.388) [20]. Hence, CEs were less likely to be hired (F_2=13.65; P<.001; η^2p=0.111) and, if hired, were offered lower salaries (F_2=13.08; P<.001; η^2p=0.107) than nonprimary caregivers [20]. Moreover, the dual role adds extra strain, negatively impacting the mental and physical health of CEs [21,22] and their performance in both roles, which aligns with the role accumulation theory [14,23].

Therefore, the strain of the dual role of CEs will likely offset the low caregiver burden associated with filial piety in Asian populations [8,16,17]. Moreover, the low dependency ratio among Asian populations is likely to be mitigated by the rapid aging of many East Asian populations by 2030, as shown by the China Health and Retirement Longitudinal Study [24]. Thus, several studies have investigated the impact of caregiver-friendly workplace policies (CFWPs) on CEs, which have been associated with the improved overall health of CEs by reducing occupational and overall stress, minimizing work interruptions, and improving performance [22,25-29]. There are also direct economic benefits accruing from adopting CFWPs. For example, educating CEs about their caregiving activities generates a net benefit ranging from US $48,010 to US $675,657 for CEs and employers [30].

CFWPs that help employees manage multiple roles and improve their work-life balance [31] are increasingly being adopted to mitigate some of the caregiving burden of CEs, especially in developed economies [32]. For instance, most employers in the United States and Canada have adopted measures to create a caregiver-friendly workplace environment, such as support services, flexible working hours, financial support, and paid/unpaid leave [33,34]. Similarly, the UK government has set up programs and nongovernmental organizations (NGOs) to help the private sector become more CE friendly [33]. In the specific context of Hong Kong, official caregiver support has not yet been observed, although some private companies provide generic support [35].

Moreover, while several studies have reported the types and impacts of CFWPs [29,33], there is a paucity of studies reporting stakeholders' perspectives on CFWPs. We could identify only 1 study that explored the perspectives of stakeholders (managers working in the Canadian health care sector) on CFWPs [36]. Therefore, this study explored the views and experiences of employers regarding CFWPs for CEs caring for older adults in Hong Kong with the objectives of identifying (1) the support that is currently provided and that could be provided to CEs by employers and (2) the challenge and facilitative support for employers to adopt CFWPs in the specific context of Hong Kong.

Methods

Setting

In Hong Kong, authoritative filial piety emphasizes caring for elderly parents [37]. However, the shift in parental expectations from tangible to emotional support poses challenges for caregiver mental health [38]. Sole children of aging parents face intense burdens, especially in nuclear families, which comprise 64% of households in Hong Kong [39]. One-third of households have at least one elderly member [39], and only 2.3% of the elderly population is entitled to full subsidization [40]. Additionally, given the 56% increase in children with special educational needs in the last half decade [41], support for people in the "sandwich generation" who are caring for both young children and old parents becomes important [28].

The number of CEs, defined as family members (spouse, parents, or siblings) who are employed with monetary rewards and at the same time provide care to another family member [42], in Hong Kong remains undocumented, as general informal caregiver support has only recently started to pick up in Hong Kong. Nevertheless, Hong Kong's highly engaged workforce (50.87% of the overall population) [43] faces additional challenges due to chronic diseases among older adults. Over 65% of the older population in Hong Kong have at least one chronic disease, while one-third have ≥2 chronic diseases [44].

Design

A qualitative research design with semistructured individual in-depth interviews involving employers and company management in Hong Kong was adopted for this study. Independent interviews helped build critical rapport between the researcher and the participants, with minimized privacy issues compared to focus groups, so that respondents would be as open and honest as possible. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist (Multimedia Appendix 1) was used as the reporting framework [45].

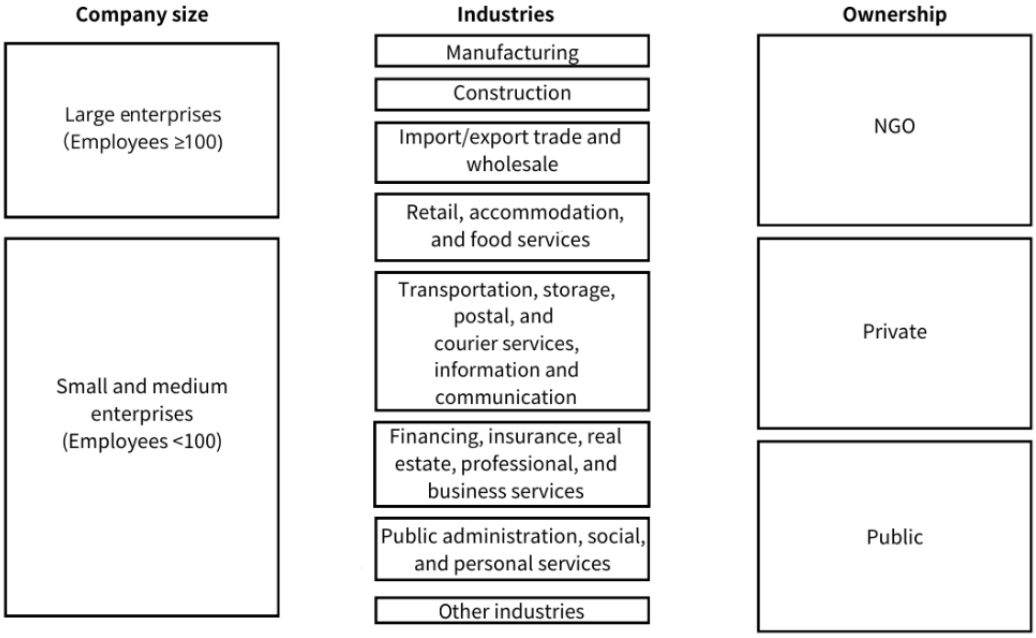
Participants

Purposive sampling was used to recruit participants, which allowed the inclusion of participants sensitized to the idea and potential of CFWPs. The list of potential participants or the sampling frame included individuals who had participated in ESG (environmental, social, and governance) policy consultations, and the information was sourced from a local NGO that advocates for working caregivers. Participants were also identified through the snowballing technique via referrals during interviews. Interviews were arranged until data saturation was achieved.

We started recruitment based on the 7 main industries in the Hong Kong census [39] and recruited from all 3 employer types (private, public, and NGO) (Figure 1). We then expanded the list to ensure a good proportion of large enterprises, small- and medium-sized enterprises, NGOs, and public institutions until data saturation was reached. Data saturation was assumed when no new themes emerged during interviews.

Participants were deemed eligible for inclusion if they had served in a managerial role for at least one staff member at a company, had experience working with CEs in a professional or personal context, and were proficient in English or Chinese (Cantonese or Mandarin). Those serving as third-party consultants for a company were excluded.

Figure 1. Map of employers and management recruited in this study. NGO: nongovernmental organization.



Data Collection

The semistructured interviews were conducted using a discussion guide consisting of 17 questions related to four aspects: (1) respondents' personal experiences with caregiver employees, (2) their attitudes and preferences for policies, (3) their perceptions of a caregiver-friendly workplace, and (4) the rating of 10 policies (Multimedia Appendix 2). The discussion guide was developed based on a thorough literature review, the first author's previous Master's thesis [35], and the opinions of 2 expert panels of researchers specializing in the field of caregiving (Professor E Wong, Professor D Dong, and Dr C Chan from the School of Public Health and Primary Care, The Chinese University of Hong Kong).

The first author (MMSL; PhD candidate at the Chinese University of Hong Kong) conducted all interviews in Cantonese face-to-face at the participants' offices or through videoconferencing, with each lasting 60 to 90 minutes. Participants' written consent and demographic data (age, gender, working position, and marital status) were obtained after the interviewer's self-introduction (comprising qualifications, current and past research focus, and experience) and an explanation of the purpose of conducting the research. Conversation starters were used to open up the participants, so they would feel more at ease and provide the most candid answers. Prompts were also used for specific and related questions during the interview to fully explore their experiences and perceptions [46,47].

At the end of the interview, participants were invited to vote for specific CFWPs based on the degree of importance (0 to 10) from the perspective of employers and managers. The list of CFWPs developed from the global literature review included caregiver-inclusive corporate culture; paid caregiver leave; unpaid caregiver leave; bereavement leave; flexible working hours; flexible work locations; switch to part-time work; unpaid leave; medical needs/insurance of employees' parents; and caregiving information, carer skills, and guide to community care resources. No nonparticipants were present during the interviews.

Analysis

Thematic framework analysis in applied policy research was adopted for data analysis. A 5-stage analytical process described by Ritchie and Spencer [48] was used, which comprised (1) familiarization, (2) identifying a thematic framework, (3) indexing, (4) charting, and (5) mapping and interpretation (Figure 2) [48,49].

Audio recordings of all interviews were transcribed and coded using NVivo software (version 12, Lumivero) independently by 2 researchers (MMSL and EW) to ensure all interpretations were agreeable and to enhance the reliability of the study. The transcripts or the findings were not returned to participants for comment or corrections. Any discrepancy in coding was resolved by discussion with supervisors.

The rating of the 10 policies by importance was reported as mean and SD. Inapplicable policies for specific industries were removed during the calculation. For example, there were no flexible work locations for the retail, food, and construction industries. A coding hierarchy chart (Figure 3) was generated to show the visual patterns of the coding.

Figure 2. The 5-stage analytical process used in this study.

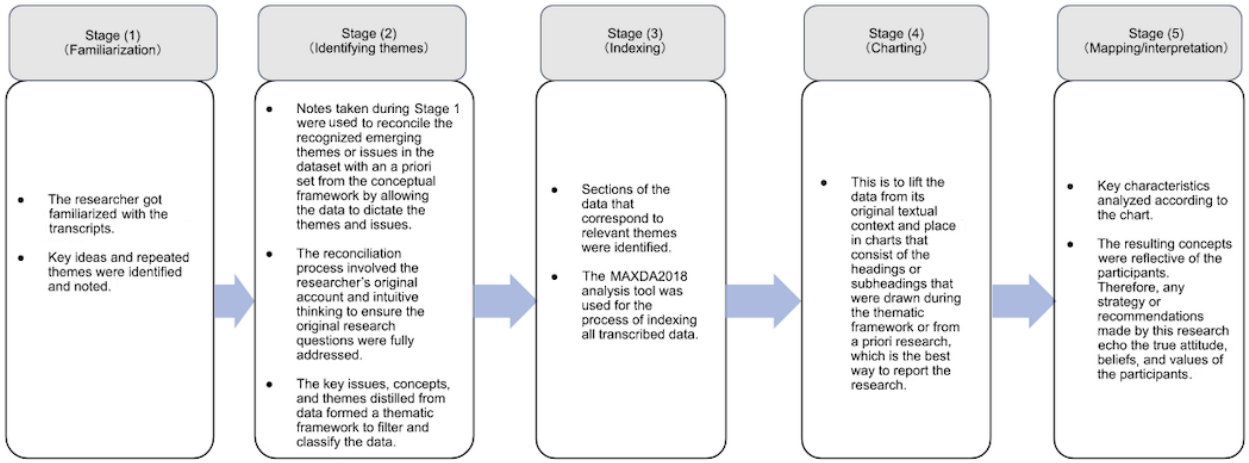


Figure 3. Coding hierarchy chart. CE: caregiver-employee; CFWP: caregiver-friendly workplace policy.

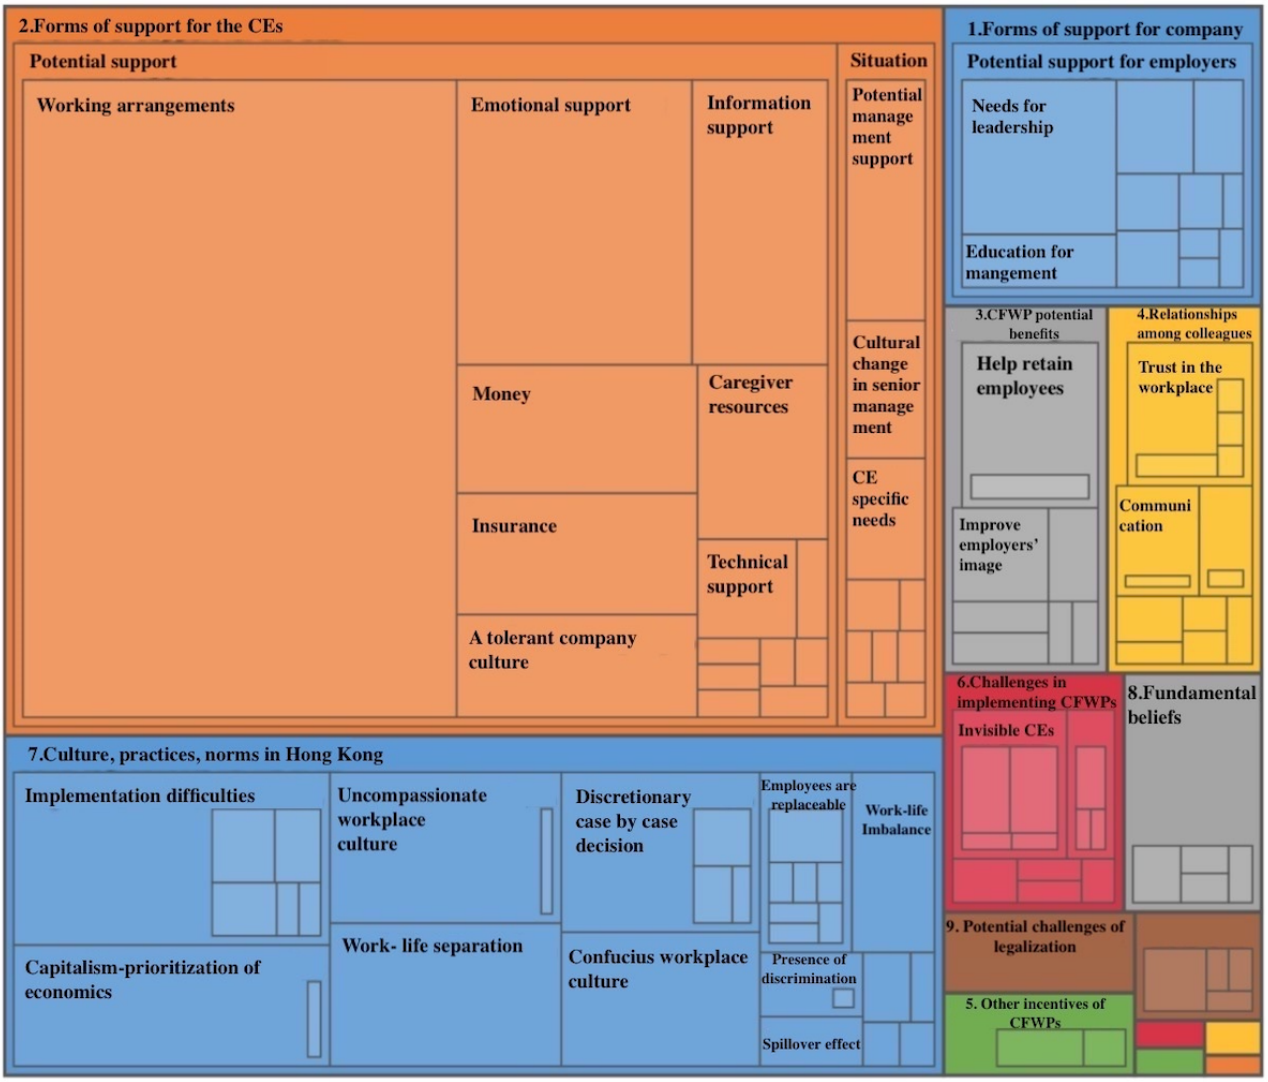

Ethical Considerations

Research ethics approval was granted by The Chinese University of HK Survey and Behavioral Research Ethics Committee (reference number: SBRE(R)-21-011). Written consent was obtained from interview participants, and they were assured of their rights and freedom to withdraw from the study at any time. The information and responses of the participants were treated confidentially. All project data were anonymized and kept in

password-protected folders that were only accessible to the project researchers and supervisors.

Results

Overview

Interviews with 17 participants comprising 4 (24%) male and 13 (76%) female participants were conducted in November 2021, and additional participants were not recruited as data saturation was achieved. Details of the participants are presented in Table 1. The age of the participants ranged from 30 to 50 years, and all held managerial positions at the time of the interview. Of the 17 participants, 13 were from private companies, 2 were from public institutions, and 2 were from NGOs. Given that the proportion of workers employed in public institutions and NGOs is less than 25% of the total workforce in Hong Kong [39], the ratio of 13:2:2 is justified.

The companies and institutions encompassed the 7 major industries in Hong Kong (ranging from 2.5 to 120,000 employees). Four of the companies had a global presence. Data saturation was achieved for NGOs and public institutions with 4 participants, all of whom viewed their industries' organizational policies and culture similarly.

Most participants (16/17) expressed that the concepts of CFWPs had been unheard of before the interviews. However, they all supported the core ideas of CFWPs (enabling the dual roles of CEs as a caregiver and a productive member of the institution) and agreed on the fact that CFWPs were needed, subject to the specific needs of the business, for the betterment of the venture and Hong Kong's future. The participants rated (1) information, caregiving skills, and guide to community care resources for CEs; (2) bereavement leave; (3) flexible working hours; and (4) caregiver-inclusive corporate culture as the most important policies (Table 2).

Despite the unanimity in supporting CFWPs, the operational practicality of CFWPs was of concern to all the participants. Four overarching themes were identified as outcomes of the thematic framework method in the analysis: (1) current support and potential support for CEs, (2) challenges in adopting CFWPs, (3) facilitating support for adopting CFWPs, and (4) incentives for adopting CFWPs (Table 3).

Table 1. Detailed demographics of the participants.

Number	Organization				Position	Age (years)/sex	Marital status[a]
	Industry	Type	Size	Presence			
1	Public administration, social, and personal services	Public	100 (LE[b])	Regional	Chief/director of a primary school	47/male	Married; #2
2	Public administration, social, and personal services	Private	8-10 (SME[c])	Regional	Executive director of a beauty company	60/female	Married; #1
3	Transport, storage, postal, and courier services; information and communication	Private	8-10 (SME)	Regional	Director of an e-platform building firm	40-50/female	Separated; #0
4	Import/export and wholesale	Private	8-10 (SME)	Regional	Director of an import/export company	30-40/female	Married; #1
5	Financing, insurance, real estate, professional, and business services	Private	200-300 (LE)	Regional	Managing director of a financial company	36/female	Single; #0
6	Public administration, social, and personal services	Private	9000 (LE)	Global	Senior marketing director of a music label corporation	48/female	Married; #2
7	Public administration, social, and personal services	Private	2.5 (SME)	Regional	Director of an individual psychiatric clinic	40/male	Married; #1
8	Retail, accommodation, and food services	Private	32 (SME)	Regional	Sales and marketing director	32/female	Single; #0
9	Public administration, social, and personal services	NGO[d]	15 (SME)	Regional	Project manager	35/female	Married; #0
10	Financing, insurance, real estate, professional, and business services	Private	20,000 (LE)	Global	District director	60/male	Married; #2
11	Public administration, social, and personal services	Public	1300 (LE)	Regional	Head of department at a financial regulatory institution	47/female	Married; #2
12	Public administration, social, and personal services	NGO	40 (SME)	Regional	Manager of a district health center	30-40/female	Married; #0
13	Financing, insurance, real estate, professional, and business services	Private	100 (LE)	Regional	Senior marketing manager of a marketing company	32/female	Single; #0
14	Public administration, social, and personal services	Private	120,000 (LE)	Global	Market access manager of a pharmaceutical company	30-40/female	Single; #0
15	Manufacturing	Private	100 (LE)	Global	CEO[e]	30-40/male	Married; #2
16	Construction	Private	10 (SME)	Regional	Owner of a construction company	31/female	Married; #1
17	Retail, accommodation, and food services	Private	11 (SME)	Regional	Owner of a restaurant	31/female	Married; #0

[a]# denotes the number of children.

[b]LE: large enterprise.

[c]SME: small and medium enterprise.

[d]NGO: nongovernmental organization.

[e]CEO: chief executive officer.

Table 2. Participant rating of the importance of the policies.

Rank	Policy	Score, mean (SD)
1	Information/caregiving skills/guide to community care resources	8.56 (0.37)
2	Bereavement leave	8.50 (0.55)
3	Flexible working hours	8.47 (0.63)
4	Caregiver-inclusive corporate culture	8.32 (0.48)
5	Flexible work locations	7.80 (0.61)
6	Paid caregiver leave (especially for those caring for elderly people with chronic diseases, excluding counting maternity leave)	7.72 (0.54)
7	Unpaid caregiver leave	7.60 (0.62)
8	Aiding medical needs/insurance of employees' parents	7.56 (0.75)
9	Switch to part-time work	7.03 (0.44)
10	Unpaid leave	6.78 (0.68)

Table 3. Themes and subthemes.

Main theme	Subthemes
Current support and potential support for CEs[a]	• Leave • Nonfinancial support • Emotional support • Information support • Technical support • Industry-specific support
Challenges in adopting CFWPs[b]	• Invisibility of CEs • Hard to adopt a fair policy for the duration of leave • Concerns about standardization
Facilitating support for adopting CFWPs	• Establishment of a government compensation fund and legal framework for caregiver leave • Government leadership
Incentives for adopting CFWPs	• Build a positive organizational culture • Recruitment of talent and extension of the worldwide network

[a]CE: carer-employee.

[b]CFWP: caregiver-friendly workplace policy.

Theme 1: Current Support and Potential Support for CEs

Six subthemes were identified based on the participants' current and potential support needs.

Leave

All participants had access to discretionary annual leave and unpaid leave when annual leave was exhausted, except participants 16 and 17, who were from the construction and food industries, which grant pay on a daily or hourly basis. All participants stated that they had the flexibility of taking a few hours of leave during working hours at their discretion for an emergency, for instance, a medical emergency related to an older family member at home. However, none of the participants reported specific caregiver policies in their workplaces.

There was bereavement leave in the participants' companies, but as noted by participant 1, such leave "is only for immediate family members." Participant 1 further noted the rigidity of bereavement leave as follows:

> *Like my wife's father, whom she also cared for, was paralyzed for a while and then passed away. I could not take leave for his funeral.*

Nonfinancial Support

Unresolved age-related care challenges created pessimism about the future among 10 participants: rising health care costs and longer life expectancy strain lower- and middle-class families, and single-child families bear immense burdens when caring for elderly people and young people. Without the financial means to hire a helper or buy insurance policies, the quality of life of CEs and their families would drastically drop in the face of immense economic, physical, mental, and emotional strains. Employers recognized the resource-based challenges CEs face, emphasized the need for nonfinancial support, and deemed direct financial support too expensive to be on the agenda for the time being. Participant 4 specifically pointed to the

importance of time as an example of nonfinancial support for working caregivers:

> *I think the most important thing is time. There are different degrees of illness; maybe he (i.e., the care recipient) has a stroke, or he has terminal cancer, a case like mine has only a few months left. And if you have to keep working and cannot spend time with your family. I think that's a great pity.*

Emotional Support

Seven participants pointed to the importance of emotional support for CEs. Participants pointed to the heavy role burdens of CEs, who need to fulfill their roles as parents, team members in the workplace, and caregivers of older adults. For instance, participant 8 witnessed severe psychological distress, possibly an emotional breakdown, during one of the work trips when her colleague was struggling with poor support from her marriage and was struggling in her career while caring for her children and an ailing elderly person. Participant 4 considered that emotional support should apply to all employees (not only CEs):

> *Emotional support should not only apply to CEs. I think the emotions of all employees are important as long as they are in the workforce. Emotional distress is like a cold, very common.*

Participant 12, an occupational therapist specializing in mental health, noted that work stress in Hong Kong is so severe that depression in young workers is often due to work stress. Long working hours and the stigma and discrimination against mental illness would further discourage Hong Kong CEs from taking care of their mental well-being. A sudden imposition of the caregiver role would further challenge the coping skills of the workers themselves and jeopardize their well-being.

Information Support

Four participants pointed out the need for a hotline for CEs to receive information and counseling services. Participant 14, who worked for a multinational pharmaceutical company, reported that they had already set up an international hotline to support employees in potentially all life-related aspects:

> *You can call there to find out about the best schools for children in your neighborhood. Since the hotline is run by a third party, anonymity is maintained to protect privacy, which makes the service even more attractive.*

Technical Support

Four participants also pointed out the problem of time strain (high time demands and little control over timing), which applies to both work and unremitting care work. They therefore pointed to the importance of home-based care services that allow CEs some personal space and time. In this context, participant 6 mentioned that today's open-plan offices prevent CEs from taking personal calls when needed. Therefore, personal space in the workplace, such as a phone box, would support CEs in fulfilling both roles effectively and safely. Participant 6 elaborated as follows:

> *Open-plan offices are very popular today, which I object to because it lacks personal space. A phone box is a personal space where colleagues have to take their own personal calls. For example, if I were to have a conversation with my mother, who is also deaf. I yell, 'No, the diarrhea pill is upstairs.' That can be very embarrassing in an open-plan office. In fact, I think this concept is in line with the idea of work-life separation.*

Industry-Specific Support

Participant 1, one of the directors at a publicly funded primary school, pointed out that staff turnover could severely affect the quality of teaching and that CFWPs were crucial to the school context, given the overly protected privacy in the school's workplace culture. No personal matters were allowed to be revealed that could cause suspicion and doubt among colleagues and between teachers and parents. According to participant 1, in this specific sector, either flexible working hours and locations or a switch to part-time work was possible. Given the bureaucracy in applying for leave and extended working hours, a CFWP culture for school teachers was necessary. Participant 1 commented:

> *Changes should be made at the top policy level of school administration. Because at the moment, even if you are a headmaster, you act according to a set of rules that restrict what you can do and what you can use.*

How wages are paid is also a determinant of whether a policy of flexible working hours is needed. In construction (daily rates), insurance (piece rates), or creative industries (commission rates), the flexibility of working hours is built into the mode of payment. Therefore, there is no substantial need to include it in CFWPs. Flexible work location arrangements are not applicable in construction, retail, food, and personal services where the location of the staff is essential to the purpose of the employment.

Theme 2: Challenges in Adopting CFWPs

Invisibility of CEs

Many challenges of introducing CFWPs are closely linked to the nature of CEs. A key feature of CEs is their invisibility. Unlike maternity leave, which 11 participants said is easier to implement than caregiver leave, no identifiable physical features (such as a swollen and protruding belly) make CEs recognizable. Participant 14, for instance, made the following statement:

> *People are very visual, maternity leave, that the colleague just had a baby. But caregivers, not everyone can see their parents or the needs of their family.*

The invisibility of CEs has enormous implications for the adoption and implementation of CFWPs, as it becomes more difficult to convince everyone of the need to support CEs and make extra efforts to accommodate them, even if maternity, paternity, and caregiving leaves are all based on the same basic need to care for family members. Participant 17 elaborated as follows:

> *[regarding employees requiring maternity leave], we can see the belly sticking out. Also, there is a life in there; you are responsible if something happens to the mother or child. You do not feel so strong if the colleague has a sick parent, for example. If the pregnant colleague feels uncomfortable with her belly and lies down, you have to let her immediately. But if the colleague says that her father is in hospital because of stomach problems, you would not feel so strongly at that moment. Besides, I have experienced that myself—some people might doubt if it is even real.*

According to the participants, CEs disclose their status as caregivers directly to their supervisors when they need to take leave or use other forms of support.

Hard to Adopt a Fair Policy for the Duration of Leave

The ambiguous needs of CEs create many grey areas for institutional arrangements. To be fair to all employees, the rationale for the arrangements should be clear and relevant, but this poses a problem for participants when it is necessary to allocate a certain number of leave days depending on the nature, severity, and stage of medical conditions. On the other hand, participants lacked the medical expertise to assess the CE's situation for a case-by-case scenario, while adopting an all-caregiver-inclusive package for all CEs could be resource-intensive and disruptive to daily operations. Thus, there was no consensus among the participants regarding standardization. Participants 9 and 11, for example, felt that standardization would provide a reference point and guideline for companies, which would help combat discrimination against CEs and give the company an advantage in hiring workers. In contrast, others, such as participant 6, felt the standardization would lack the flexibility to be helpful. This complex and difficult-to-standardize situation of CEs contrasts with maternity and paternity leaves, which are standardized and predictable.

This ambiguous need of CEs further discourages companies from using CFWPs when they entail prohibitive costs in the long run. Participant 15 explained:

> *There is a predictable time frame for maternity and paternity leave... But sickness is a bit longer. For maternity or paternity leave, you would give birth to maybe only two to three children in this lifetime and then stop, so you would only take maternity/paternity leave two to three times; here, there is a fixed number of dates, you can predict it. But if you are taking care of chronically ill or dependent family members, it may take a long time; it may be 5 or 10 years. In between, you may have to take leave every time to accompany them to doctor's appointments, which may happen 10-20 times a year; that possibility actually exists. So, with that uncertainty, it becomes a bit more difficult to implement* [the CFWP policy]

Concerns About Standardization

Standardization also raises concerns that the mechanisms of CFWPs could be abused. Participant 16 pointed to the difficulty of proving caregiver status:

> *Can I just find any aunt or distant relative? That is, the moment I want to take a holiday, the moment I do not want to take this job, I can just find a random aunt. They give me a paper, I give it to the company, then I get the benefits. I feel that these grey areas can be abused very easily... If I introduce care leave as an employer, I may suddenly get them [these medical certificates]. The next day, I wake up and suddenly get a message that I can not go to work [because of a family member's condition]... The wheel would stop turning; we would not know what to do, so I think this thing is more difficult than paternity leave. With paternity leave, you can easily prove that you are the father. Due to the very ambiguous nature of CEs' needs, this can be a major trust issue for management to support CEs.*

Participants commonly expressed that it was difficult to justify the CFWPs giving priority exclusively to workers caring for older individuals, risking favoritism over other needs, such as workers raising their children. The heavy workload of CEs for ailing older individuals would not make caring for needy young individuals less stressful. The cultural preference for newborns in Hong Kong was pointed out by participant 4 as follows:

> *Everyone expects a happy baby, but not everyone would consider the possibility of having a sick parent.*

The comments make the different treatment of CEs with an ailing older relative even more challenging to accept.

Theme 3: Facilitating Support for Adopting CFWPs

Governmental Compensation Fund and Legal Framework for Caregiver Leave

Addressing paid/unpaid leave for caregivers involves considering financial costs, a central issue raised by all participants. Participants proposed government compensation funds for employers to cover the costs of CEs' time off, cashing out the mandatory provident fund (MPF) during a medical crisis, legal frameworks for eligibility, and compulsory employment insurance. Regarding the cash out from the MPF, participant 17 commented:

> *The original intention of the MPF was to maintain a certain quality of life in retirement. But if he (CE) can't get through the hardest time of his life (caring for ailing older family members), it doesn't matter how much money he'll receive in the future.*

Government Leadership

The practical challenges practicing doctors face include a lack of government guidance and reimbursement. Many participants felt that the government must take the initiative to support CEs. Many participants expressed the opinion that "if the government implements it first, we will follow;" however, there is currently no single, consistent CFWP in Hong Kong. Therefore, support for CEs has only been granted on a discretionary and case-by-case basis. If enacted, the policy and legislation supporting CEs would be mandatory for them to follow, and this government initiative would even trigger a shift in

companies and management thinking. Participant 2, for example, said the following:

> *I do not think there was anything like maternity leave before; it's even more similar with paternity, but we all have that now, so I would think, why not? [I am] also very, very supportive* [of CE leave]

Two participants also felt that with the introduction of maternity and paternity leaves, it would be easier to advocate for support for caregivers if the government takes the lead in implementing policies. Participant 2 commented as follows:

> *There is paternity leave now. Before, it was difficult, but now it is possible. If this was applied to CEs, maybe it would be quicker [to get support for them] because people have already taken a step forward.*

This was also affirmed by participants 3 and 8, showing some level of readiness for CFWPs in Hong Kong, but it is crucial for the government to take the lead in getting this process started.

In the context of introducing a legal framework to support the future implementation of CFWPs, participant 11, a department head of a financial regulatory institution, highlighted the earlier success of the pilot project on maternity leave before it was legalized for all companies:

> *The Government could test the leave program for CE and other CFWP in some selected departments to identify the need and the possibilities of implementation. After consultations with various sectors of the economy, I believe it would be readily adopted.*

All participants expressed willingness to introduce some forms of CFWPs if the government could first demonstrate the benefits of the measures and set the framework for practice. Participant 13 felt that a pilot phase within the government is a guarantee for the private sector and is one of the many conditions for local businesses to consider CFWPs.

Four participants were aware of the importance of the government communicating the needs of CFWPs to the business sector, particularly for management understanding, including recognition of the role of CEs, potential caregiver burnout, disease progression, management of older people, and stigma/discrimination against CEs. Participant 6, a director at a multinational company, emphasized that the human resources department could take the lead in advocating for CFWPs in the cultural and operational contexts to ensure sustainability and enforcement. Participants 4 and 6 recommended using case studies by the government or those in business to explore the positive changes associated with CFWPs and motivate other companies to create a caregiver-friendly workplace.

Theme 4: Incentives for Adopting CFWPs

Build a Positive Organizational Culture

The improvement in loyalty and sense of belonging that CFWPs bring in the long term was acknowledged. Participant 10, a district director of a financial institution, noted the following:

> *supporting CEs will result in productivity losses—as an immediate loss to the company, but in the long run, the benefits of improving loyalty and sense of belonging would outweigh the costs overall.*

Participants 2 and 5 noted positive spillover effects, specifically, work engagement improving the caregiving experience. CFWPs aim to facilitate a balance between the dual roles, allowing for healthier management of CEs' circumstances, which is an incentive for adoption. Participant 5 commented:

> *It's better to stay at work than to stop for caregiving because you still get to see what's going on in the world, and your brain keeps moving.*

Round-the-clock caregiving duties could be more stressful than taking on dual roles.

CFWPs could be seen as a confidence-building exercise between the management and employees. Management's effort to cultivate a caregiver-friendly workplace culture is a prerequisite for gaining CEs' trust before disclosing their status and asking for consideration for their individual needs. Participant 6 referred to her experience as follows:

> *When my employee came to my office and asked for a day off to take care of his parents, he must have trusted me that he was asking for help. I am very grateful for that trust.*

To strengthen trust, participant 4 suggested using a medical certificate (similar to a carer's passport scheme in the United Kingdom [50]) confirming the caregiving role of the employee, with constant updates on the care recipient's illness, and indications of possible commitments and the durations of such commitments. Participant 3 was aware of the guilt of CEs about not being able to fulfill the dual roles simultaneously. This sense of guilt could not only hinder productivity but also encourage the suppression of emotions and interfere with communication.

Recruitment of Talent and Extension of the Worldwide Network

Most participants explicitly expressed their belief that CFWPs could give companies an advantage in recruiting talent. Participants considered that CFWPs allow for the retention of highly qualified staff and thus more sustainable productivity, as well as a potential reduction in training and recruitment costs. However, participant 12 stressed that the attractiveness of CFWPs might be limited among younger workers.

Participant 14 emphasized that if nonfinancial reporting is considered, CFWPs could make a company a worthwhile investment for potential investors under ESG standards:

> *Impact investing is now becoming more popular. Many global companies have already included ESG in their reporting; we are already lagging behind a lot, although our company has already set up a hotline for general employee concerns.*

For Hong Kong, there are overall benefits of companies taking up CFWPs, namely keeping workers employable rather than out of the workforce for a significant duration, attracting foreign talent to Hong Kong, and reducing public health costs when CEs perform caregiving duties more efficiently and effectively.

Discussion

Principal Findings

Although support for CEs in Hong Kong is currently discretionary and depends on the context of industries, this study identified strong motivations for Hong Kong employers to adopt CFWPs. While improving mental well-being can lead to a direct improvement in productivity [51-54], the benefits of CFWPs may be more extensive than anticipated. Beyond indirect operational incentives, such as employee loyalty and talent retention, CFWPs could make a company an attractive investment for socially conscious investors under ESG standards [55]. Furthermore, CFWPs can have a positive spillover effect with a potentially significant impact on CEs' mental well-being, especially when caregiver-inclusive corporate culture is more explicit than making decisions on a case-by-case basis.

Although this study identified several gaps and barriers to the large-scale adoption of CFWPs in Hong Kong, there is ample precedence of organizational changes in Hong Kong's public and private sectors. For instance, the 8-step theory of change by Kotter [56], which involves the following steps: (1) create urgency, (2) build a guiding coalition, (3) form a strategic vision, (4) communicate the vision, (5) empower others to act on the vision, (6) generate quick wins, (7) sustain momentum, and (8) institutionalize new approaches, has been shown to be applicable across Hong Kong's monolithic civil service organizations [57], publicly listed corporations [58], and NGOs [59,60], which represent the 3 primary stakeholders for the large-scale adoption of CFWPs in Hong Kong.

In line with the theory by Kotter [56], employers and management participants in this study echoed the prerequisites for the government to take the leadership in raising awareness of the needs of CEs (step 1: create urgency) and advance the discussion on CFWPs among stakeholders (step 2: build a guiding coalition) to develop (step 3: form a strategic vision) and implement (step 4: communicate the vision) goal-oriented strategies. Government leadership is indispensable for small and medium enterprises as, unlike large enterprises, they lack the in-house resources and experiences to formulate relevant policies and account for more than 98% of businesses in Hong Kong [61] (step 5: empower others).

The piloting of CFWPs in the management of public institutions seems to be an appropriate starting point, as this is where the bureaucratic burden is most remarkable (step 6: generate quick wins). CFWPs could be better thought through in this complex environment before being rolled out to the private sector and NGOs. Notably, the government has recently launched a 2-year pilot program to subsidize caregivers from low-income families caring for older individuals with moderate and severe impairments (at least 3 hours of care per day) to the tune of HK $3000 (US $386) per care recipient [62]. However, the number of households benefiting from such high thresholds is questionable, and the policy does not extend to caregivers who continue to work and contribute to the economy.

Furthermore, our participants indicated the need for a general CFWP with some specific policies for certain industries (step 7: sustain momentum). For instance, information, caregiving skills, and guide to community care resources; bereavement leave; and caregiver-inclusive corporate culture can apply to all industries. With Hong Kong well-positioned as a knowledge-based economy [63], these CFWPs may be immediately relevant for human capital and knowledge-intensive industries, such as social and personal services, professional and business services, financing, insurance, and real estate. However, flexible working hours or locations depend on industry-specific payment arrangements and the individual requirements of the working environment. For instance, construction, retail, accommodation, and food service sectors may require special considerations due to their demographics (eg, relatively younger workers) and wage payment mode (eg, piecework in construction and hourly in food services).

According to the rated importance, providing information resources, cultivating a caregiver-inclusive corporate culture, and introducing flexible working hours and locations could be piloted within the government structure to provide feedback for future public implementation (step 8: institutionalize new approaches). In addition, legalizing paid or unpaid caregiver leave is necessary. While the government reimburses companies for maternity and paternity leaves, there are other options to facilitate the future legalization of caregiver leave, such as cashing out from the MPF and introducing a legal framework on the qualifications and durations of leaves for CEs. However, cashing out from the MPF could jeopardize the original intention of securing financial security in retirement. Thus, a greater government-industry engagement focused on CFWPs is essential.

Our study underscores the need for consensus among stakeholders on caregiver eligibility criteria, including the care recipient's age, care forms, employment conditions, relationships, and medical needs. Quantifiable parameters can ensure fairness and prevent policy misuse. For instance, the voluntary leave-sharing program in the United States allows workers to donate their unused annual leaves directly to another worker who is experiencing a personal or family medical emergency and has exhausted available paid leaves [64,65]. However, the program requires a significant income loss (at least 24 hours for full-time employees) due to illness after exhausting paid leaves [64,65]. Such a program with objective and fair parameters may be considered for Hong Kong's different industrial sectors. Furthermore, such programs may be instrumental in breaking the status quo that personal or family matters do not belong in the workplace and may enable generous interworker benefit transfers.

There is some international precedence in identifying the pathway to develop and implement CFWPs in Hong Kong. For instance, the advocacy of CFWPs is typically supported by NGOs working with governments and legislatures to inform and influence policy [66-68]. While such advocacy groups do not exist in Hong Kong yet, they can be a vital conduit for engaging with CEs and negotiating with the government to address their most pressing needs. Similarly, Canada offers caregivers the world's longest unpaid compassionate leave (26 weeks) [69,70]. Caregiver leave to attend to an ailing parent is covered by compulsory employment insurance, which is funded

by worker premiums, without burdening businesses directly [70]. Similarly, the Japanese government has subsidized 93 caregiver leave days for the business sector [71].

Notably, the legalization of caregiver leave in Taiwan and Japan was in response to an alarming number of caregivers committing suicide or murdering elderly members under overwhelming "caring fatigue" [72]. Hong Kong should urgently consider CFWPs before caring for the needs of the aging population takes too heavy a toll on the working population. Although successful precedents in other countries can be a good starting point, it is essential to consider the unique needs and expectations of CEs and their employers in Hong Kong. For instance, while unpaid caregiver leave is legalized for CEs in Taiwan and Japan [68,71], employers in this study emphasized the importance of paid leave over unpaid leave in line with maternity and paternity leaves in Hong Kong.

Limitations

Our study has several limitations that must be noted. First, our participants were predominantly recruited using the chain-referral method, which is known to introduce selection bias [73]. Thus, the findings may have lower generalizability, representativeness, or external validity than research conducted with a random sample [73]. However, our goal was to identify perceived barriers to CFWP implementation and galvanize further research in this domain, which may, in turn, identify additional barriers. Thus, in this type of research, the inherent risk of selection bias due to chain-referral sampling is not expected to skew the findings significantly. Second, some industries may be underrepresented in our study. For instance, while data saturation was achieved with at least two participants for each category by size (ie, small and medium enterprises and large corporations) and constitution (ie, NGOs, public institutions, and private companies), there was at least one participant from each of the main industrial sectors in Hong Kong. Third, there was no "third party" interviewer to reduce the impact of the researchers' biases and beliefs [74] about the phenomenon (ie, CFWPs) on the quality of the data collected. Finally, this research was conducted at the peak of the COVID-19 pandemic, which could have influenced the participants' perspectives and positions on CFWPs [75]. In addition, the pandemic conditions may have led to the unavailability of participants with diverse opinions [75].

Conclusion

Employers and management recognize the importance of CFWPs, but current support for caregivers is discretionary and industry-specific. Government leadership is crucial for the future implementation of CFWPs, and piloting such policies within the government can drive institutional change. Ongoing consultation with the business sector on the specific needs of particular industries is essential before legalizing unpaid or paid caregiver leave in Hong Kong.

Abstract

Background: Caregiver-assisted medication management plays a critical role in promoting medication adherence and quality of life for people living with Alzheimer disease or related dementias (ADRD). The current landscape of digital and nondigital interventions to support medication management does not meet caregivers' needs, contexts, and levels of technological proficiency. Intervention development can be facilitated using personas or data-driven archetypes that represent end users' traits relevant to solution design.

Objective: This study aims to understand the strategies and unmet needs of ADRD caregivers who manage medications and use this understanding to create personas that can inform customized caregiver interventions.

Methods: Participants were self-identified primary caregivers of people with ADRD living with or near the care recipient. Virtual contextual inquiry was completed in three stages: (1) enrollment interview, (2) virtual observation over a 1-week period, and (3) postobservation interview. Codebook thematic analysis of interview transcripts was used to identify dimensions of caregivers' approaches to medication management. A reflexive, team-based affinity diagramming approach was used to identify attributes within these dimensions and group attributes into personas.

Results: Participants (N=25) were aged 62.32 (SD 11.86) years on average, and 17 (68%) of them were female. Caregivers varied across 6 dimensions relevant to medication management: strategies for medication acquisition, medication storage and organization, medication administration, monitoring the care recipient for symptoms, communication with care network regarding

medication, and acquiring information about medication. Three personas were created to represent the observed strategies, unmet needs, and levels of technology use related to medication management: Checklist Cheryl, in Control; Social Sam, Keeps it Simple; and Responsive Rhonda, Stays Relaxed.

Conclusions: Caregivers in this study demonstrated a range of characteristics and values that informed their approach to medication management. They used a combination of technology-based strategies and strategies situated in their physical environments to manage medications. The personas created can be used to inform interventions, such as digital tools, that address caregivers' unmet needs.

Introduction

Overview

Every year, family and friends of people living with Alzheimer disease or related dementias (ADRD) around the globe provide 82 billion hours of care [1]. These family caregivers assist in promoting the health and safety of the persons living with ADRD, including helping them manage complex medication routines [2-5]. A US-based survey of family caregivers found that medication management is a challenging process due to the considerable time involved, the complexity of routines, fear of making a mistake, and care recipients' resistance to taking medication [6]. Caregivers of people living with ADRD may face unique challenges; for example, an Australian study of family caregivers found that people living with ADRD may not recognize their need for assistance with managing medication and may feel embarrassed to accept help [7]. International reviews of the literature further suggest that caregivers of people living with ADRD lack training and resources to support the breadth of activities associated with medication management [5,8]. Thus, ADRD caregivers would benefit from interventions that are tailored to their needs, contexts, and levels of technological proficiency to facilitate safe and successful medication management [9]. Intervention development can be facilitated using personas or data-driven archetypes that represent end users' traits relevant to solution design.

Background

Challenges With Caregiver-Assisted Medication Management

Medication management is a complex, multifaceted process [10]. One aspect of caregiver-assisted medication management (henceforth, medication management) is maintaining a constant supply of medications, which is made more complicated by differences in prescription pack sizes, delays in prescription refill, receiving incomplete prescriptions, and return visits to the pharmacy when concerns or errors are detected [10]. Administering medications is complicated by the intricacies of many medication routines, frequent changes to these routines (including the dose, number, and form of medications), and both caregivers' and care recipients' forgetfulness to take medications [5,10]. Caregivers are also responsible for making judgments, such as when to withhold, increase, decrease, or discontinue medication, which involves monitoring the care recipient's symptoms, medication side effects, and whether medications are having their intended effect [10]. Finally, communication with the care team is a key but ambiguous component of medication management; caregivers may struggle to know when to reach out to prescribers or to feel comfortable reaching out and may receive incomplete information about medications from health care providers (eg, side effects to look out for or changes to a prescription) [10,11]. Thus, medication management can represent significant and taxing work for family caregivers.

Caregiver-Assisted Medication Management and Well-Being

Medication management has implications for the health and well-being of both the care recipient and caregiver. For the care recipient, international research spanning the United States, Europe, Canada, Japan, and Australia has linked suboptimal medication management with poorer health [12], poorer management of comorbid conditions [13], costly hospitalizations [14], and premature institutional placement [15]. With assistance from caregivers, medication adherence rates among those with ADRD can match those of their peers without cognitive impairment [3]. Among caregivers, performing medical tasks has been associated with positive outcomes, such as gaining new skills and feeling closer to and less worried about the care recipient [6]. However, medication management has also been associated with greater caregiver burden and stress in international research [7,16-18]. In the United States, nearly 20% of family caregivers who perform medical tasks for the care recipient describe fear of making a mistake, 32% report continuously monitoring for something to go wrong, and 40% report feeling "down, depressed, or hopeless" as an outcome of performing these tasks [6]. Therefore, it is critical to understand the unmet needs of caregivers managing medications as the first step in maximizing the positive and mitigating the negative outcomes for care recipients and caregivers alike.

Limitations of Existing Medication Management Tools

Many tools already exist to support medication management, from low-tech tools (eg, plastic cups and sandwich bags) to high-tech tools (eg, electronic pillboxes) [9]. Some caregivers' needs are met by their existing approaches, and, for them, no intervention may be needed [9]. However, other caregivers report that current low-tech tools, such as pillboxes and reminder notes, do not meet their needs [19]. Pillboxes may not accommodate more complex medication routines, and reminder notes may be ignored over time [19]. While digital interventions

abound, a recent systematic review of mobile apps available in Google Play or iTunes intended to assist with medication management suggested that these, too, may not meet users' needs [20]. The reviewed apps were largely low quality and missing desirable features, such as refill reminders and information about adherence [20]. In a US-based study of family caregivers, participants perceived existing digital interventions for medication management as too elaborate or overwhelming [9]. Thus, it is evident that current interventions to support medication management do not meet the full range of needs, contexts, and interests in technology of the current population of ADRD caregivers. By examining the strategies currently used by caregivers to manage medication, we can better understand the features of interventions that would support medication management [21].

A Call for Customized Solutions

Each caregiver's medication management needs and contexts are different [22]. Needs may vary based on the nature of the routine [23-25], qualities of the care recipient [6,8,26,27], and caregiver characteristics [28,29]. The routine itself is shaped by the variety of medications prescribed, the number of prescribers, and the use of multiple pharmacies [23-25]. Qualities of the care recipient include the stage and symptoms of dementia [8] and any co-occurring medical conditions [6], both of which may change over time, in turn, prompting changes to their medication routine [26,27]. Caregivers vary in their health literacy, access to information, commitment to self-care, and valuing of the care recipient's independence [28], all of which may affect how they manage medication. Caregivers also differ on the degree to which they receive support from others with caregiving, including medication management [8]. One analysis that identified typologies of caregiver support networks found that male caregivers and low-income caregivers in the United States were more likely to be in low support caregiving networks, that is, networks in which caregivers receive less support for themselves (eg, emotional support and support with housework) or for the care recipient (eg, personal care and transportation) [29]. In summary, the intricacies of medication management intersect with the characteristics of caregivers and care recipients to yield distinct requirements of supportive interventions.

Translating Unique Needs Into Solution Design

There is an outstanding need to understand the variable needs of caregivers managing medication on behalf of people living with ADRD and design solutions to meet those needs. Furthermore, in the design of solutions to address these caregiving challenges, it is critical to involve caregivers themselves [30]. User-centered design (UCD) is an internationally recognized approach for integrating future end users into the design of interventions that aim to meet their unique and complex needs [31]. UCD is defined as "an approach to interactive systems development that aims to make systems usable and useful by focusing on the users, their needs and requirements" [31]. UCD engages representatives of the user population in the design of interventions, resulting in interventions that are usable, useful, relevant, and adaptable to caregivers' needs [21,32]. UCD has proven valuable to the design of solutions in the health care domain across the globe to meet diverse patient population needs [30,33-35].

Within the field of UCD, persona design is a specific method in which real participant data are analyzed and distilled into archetypal end-user representations or personas [36]. Personas can be used to represent the range of key user dimensions regarding a certain process (eg, medication management), including relevant demographic characteristics, strategies they use to do their work, and any unmet needs they encounter [37]. In the context of intervention development, personas have certain advantages over other products of qualitative inquiry, such as theory, themes, or concept maps; they offer concise, data-driven representations of end users, allowing designers to ask and answer the question, *What do our end users need?* [36]. Personas may be particularly helpful for informing digital caregiving designs, including home monitoring systems, automated support with caregiving tasks, social robots that provide comfort to care recipients, and social networks that provide support to caregivers [38]. Persona development is a life cycle; initial personas are somewhat crudely defined by their distinguishing features (conception), enriched with storytelling and stakeholder feedback (gestation), and iteratively refined as they are applied (adulthood) [36]. Previous studies in the United States [39,40], Singapore [41], and Germany [42] have used personas to depict important variations among the target populations of interventions and to infer the necessary intervention features to meet users' unique needs.

Study Purpose

This study aimed to answer the following research questions (RQs):

- RQ1—What are the strategies used by caregivers of people living with ADRD who manage medication?
- RQ2—What are the unmet needs of caregivers of people living with ADRD related to medication management?
- RQ3—How can the answers to RQs 1 and 2 be represented as personas to inform intervention development?

Methods

Ethical Considerations

This study was subject to an expedited ethics review and received approval from the University of Wisconsin–Madison Institutional Review Board (2021-0339). Participants provided verbal consent to participate and were told that they could withdraw consent at any time. All data were deidentified before analysis. Participants received US $25 for completing the enrollment interview and another US $25 for completing the postobservation interview.

Study Design

To identify the approaches and unmet needs related to the daily work of medication management for caregivers of people living with ADRD, we adapted a design research method, contextual inquiry, to a virtual form, which we have termed virtual contextual inquiry (VCI) [43,44]. Traditional contextual inquiry combines principles of ethnography with cognitive task analysis, seeking to understand how tasks are completed in naturalistic

environments, including the implicit and tacit knowledge obtained from repeatedly performing contextualized work [45]. In traditional contextual inquiry, researchers observe people in their natural environments while they perform tasks of interest (eg, medication management) as they normally would. Interview probes are inserted unobtrusively before, during, and after observation. In VCI, participants send the research team multimedia messages (eg, photos and textual descriptions of work) during or soon after completing the work [43]. These multimedia messages allow for nearly real-time observation of tasks and serve as a cognitive aid during the postobservation interview [46,47]. As with in-person contextual inquiry, in VCI, data collection is structured across 3 phases: before, during, and after observation.

In this study, VCI was selected over traditional contextual inquiry for myriad reasons. First, medication management takes place in various physical spaces and may vary depending on the day [10]. In order to gain a more accurate picture of the work, observation must be close and sustained. However, to observe participants in person over multiple days would be costly and time consuming for the researcher as well as inconvenient and even uncomfortable for participants [48]. Virtual observation thus strikes a balance between practicality and comprehensiveness [46,49]. Virtual observation may also improve the accuracy of data; participants who are less conscious of being observed may be less likely to alter their typical behaviors [50,51]. Furthermore, virtual observation inherently creates artifacts that can be repeatedly referenced throughout analysis, meaning researchers are less dependent upon memory or written notes. Finally, VCI allows for widespread recruitment, rather than recruiting solely from areas within geographic proximity to the research institution, and permits scholarship to continue in the face of circumstances that prevent in-person observation (eg, the COVID-19 pandemic) [48].

Conceptual Framework

Our conceptual framework for medication management, which influenced the enrollment and postobservation interview process, was based on the findings of Smith et al [10] related to contexts in which medication-related problems can occur for family caregivers managing medications. We were also guided by previous research on crafting personas for intervention design and thus inquired about participants' unmet needs and technology use [36,52].

Study Sample

This study used 2 different methods to enroll a convenience sample of caregivers of people living with ADRD. In the first method, participants were recruited from the Wisconsin Alzheimer's Disease Research Center's registry of self-identified primary caregivers and in the second method from the research team's ADRD caregiver registry. The eligibility criteria included (1) self-identifying as a primary caregiver for a person living with ADRD; (2) aged ≥18 years; (3) managing medication for a person living with ADRD, as defined by our conceptual framework; (4) currently living with or close to a person living with ADRD; (5) having access to a cellphone during the study period; and (6) speaking English.

Study Procedure

Recruitment

Participants who were recruited from the Wisconsin Alzheimer's Disease Research Center emailed the study team if they were interested in participating. The study information sheet was then shared with the participant, and a phone screening was scheduled. Members of the study team's caregiver registry were first contacted by phone, as they had previously indicated a willingness to be contacted regarding research opportunities. For both recruitment methods, after the screening call was complete and participants provided verbal consent to participate, the enrollment interview was scheduled. Those eligible and willing to participate completed the VCI process, which consisted of three stages: (1) enrollment interview, (2) virtual observation over a 1-week period, and (3) postobservation interview. The interviewer (PL) and participants were unknown to each other before recruitment, and participants knew only the interviewer's professional status as a doctoral student.

Enrollment Interview

The enrollment interview was a 1-hour audio-recorded session that took place over a secure videoconferencing software. During the interview, participants were introduced to the text messaging procedure to be performed during the observation period. Participants were provided with examples of multimedia text messages that would meet study criteria, invited to add the study team's phone number as a contact in their phone, and practiced submitting a message to the study phone. Participants were also provided with an instructional video that detailed how to submit a message. The interviewer (PL) cautioned participants against submitting messages that contained identifying information. Following this, participants indicated 2 times in the morning and evening at which they would like to receive prompts to submit a message from the study team. The interviewer scheduled a final interview that would occur after the observation period and approximately 8 to 10 days from the enrollment interview. Finally, participants completed a demographic survey and were asked to describe their daily, weekly, and monthly medication management activities. On the basis of this information, the interviewer created an initial list of potential persona dimensions (eg, *medication administration*), which were brought to the research team for discussion and refinement.

Observation Period

During the observation period, participants sent multimedia text messages (eg, textual descriptions, still photos, videos, and audio files) that described their medication management to a secure phone dedicated exclusively to study-related communication. Participants were asked to send at least 2 multimedia text messages daily for 7 days, capturing the medication management activities they performed. At the beginning and end of each day, participants received a text message reminding them to send messages. All messages were deidentified to protect the identity of the participants and uploaded to a shared and secure cloud-based drive. After each participant's observation period, the research team met to review their observation data and made notes of any multimedia

messages that needed more clarification in the postobservation interview (eg, if the tasks pictured were not clear or if any essential context was missing). In this meeting, the research team also used the caregivers' messages to summarize their approach to medication management, which would later be presented to the caregiver for feedback in the postobservation interview.

Postobservation Interview

We conducted a 1-hour postobservation interview via videoconferencing software within 8 to 10 days after the enrollment visit. During the interview, an interviewer trained in contextual inquiry reviewed the participant's multimedia messages and probed for detail. The interview followed the standard procedure for contextual inquiry in that questions did not follow a predetermined interview guide but instead were specific to the data supplied by participants [53]. For example, one participant (P15) shared an image of the spreadsheet they used to track medications. The interviewer asked, "Can you talk a little bit about how you started using that [spreadsheet] or how you came up with that?" Another caregiver (P33) shared over text that the care recipient had missed a dose of their medication, which meant that the caregiver had to remind them to take it. The interviewer asked, "How did you know he missed his medication, and then how did you go about reminding him?" Finally, the interviewer presented the participant with their summarized approach to medication management for reflection and refinement. The interview was audio recorded and transcribed for analysis.

Analysis

Overview

There is no single, standardized approach to persona development [39-42,53,54]. Our approach combined positivist and nonpositivist approaches [55]. We first used a structured, positivist approach to identify dimensions of medication management. We used this approach under the assumption that there were a finite number of medication management activities in which caregivers could engage, many of which could have been anticipated before analyses. It was reasonable to assume that 2 coders could identify the same activities, regardless of their perspectives.

With that in mind, we first used Microsoft Excel to conduct a codebook thematic analysis of postobservation interview transcripts to identify dimensions of medication management [55]. Initial dimensions were those generated by the interviewer in the enrollment interview. Four coders (PL, AL, JRL, and Mengwei Tang) coded the first 2 postobservation interview transcripts as a team. During that process, the coders refined the initial codebook, adding or modifying dimensions, definitions, and examples. The initial codebook was then brought to the entire research team and refined through consensus-based discussion. The codebook was then applied separately to the remaining transcripts by the 4 coders, such that each transcript was coded by 2 coders. To promote reliability, coders met weekly to discuss their coding and resolve any discrepancies through consensus-based discussion [56]. The coding team also met regularly with the full research team to discuss coding and resolve any discrepancies [56]. Any emergent codes or proposed changes to the codebook were brought to the entire research team for discussion and approval. The resulting final codebook represented an enumeration of the initial persona dimensions.

We then adopted a nonpositivist approach to move from dimensions to interpretive stories, in this case, toward personas and their attributes. This shift was consistent with a philosophical assumption held by the research team that, while it is possible to identify objective and discrete dimensions of medication management (eg, *medication acquisition*), we were unlikely to identify discrete types of people through our analysis. The enumeration of attributes within these dimensions and the assignment of attributes to personas were assumed to be subjective and interpretive, a product of the minds that performed the work [55].

To move from dimensions to attributes, we identified passages coded to a specific dimension and created a sentence-length paraphrase of each passage. These paraphrases were transferred to virtual sticky notes, color-coded by participant ID, and grouped by perceived similarity in an iterative team-based affinity diagramming process. For example, within the dimension *approach to medication acquisition*, sticky notes perceived as describing a proactive approach to medication acquisition were grouped together to form an attribute. If it was perceived that participants with this proactive approach to medication acquisition tended to use a strategic approach to storing medications, these attributes were spatially positioned near each other on the virtual sticky board. Each participant was assigned a distinct color sticky note. If, for example, three distinct colors appeared in the same regions of the whiteboard, it practically meant that those three participants shared an attribute. When multiple participants seemed to share multiple attributes, it warranted the creation of a persona. A process of crystallization was used to add depth and nuance to the final personas [57]. Transcripts were critically reviewed by a research team member (PL) to look for information that could add detail to the developed personas, ensure all perceived attributes had been represented by a persona, and check that no persona too closely resembled any one participant. The cowriting of this manuscript allowed the multidisciplinary research team to compare understandings of how attributes fit or did not fit within each persona. Member reflections (a Big Q alternative to member checking) were also used to refine personas [58]. The research team shared drafts of personas with 7 ADRD caregivers who were not involved in the study and augmented the personas based on their feedback. This approach was not intended to *verify* personas but rather add further depth and nuance to the research team's interpretations.

Research Team Positioning

Members of the research team held professional positions that inevitably influenced their perceptions of attributes and the creation of personas. Four members of the research team were faculty (RJH and NEW) or doctoral students (PL and AL) in the field of human factors engineering, which meant that attributes likely to shape or pose a barrier to work performance were naturally emphasized, along with attributes with

implications for product design. The lead author of this paper (AJ) was a licensed mental health counselor with training in theories of personality and thus brought assumptions about the likelihood that certain attributes would or would not co-occur. The collaboration of a pharmacist (NC), geriatrician (MB), and a research health scientist specializing in human-computer interaction (HP) added depth of understanding to topics relevant to the RQ.

Results

Overview

We reached out to 40 caregivers, and 25 (62%) of them enrolled in the study.

Caregivers who chose not to enroll largely did not respond to our outreach; of those who did respond, 10% (4/40) were ineligible, 3% (1/40) were unable to find time to schedule the enrollment interview, and 3% (1/40) were not interested in sending multimedia messages.

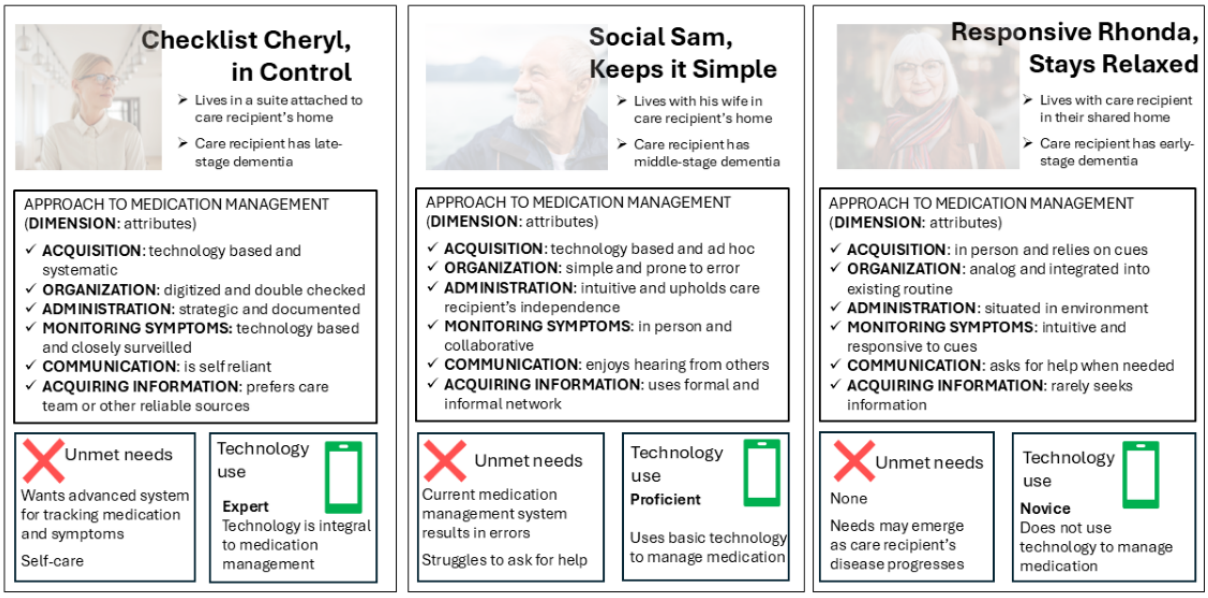
On average, participants were aged 62.3 (SD 11.9) years; 68% (17/25) of the participants were female, and all (25/25, 100%) identified as White and not of Hispanic or Latino origin. The care recipients, on average, were aged 76.7 (SD 11.1) years, and 12% (3/25) were aged <65 years. Among care recipients, 48% (12/25) were female, 92% (23/25) were White, 4% (1/25) were Black or African American, and 4% (1/25) were of Hispanic or Latino origin. All (25/25, 100%) participants demonstrated multiple medication management activities over the course of the 7-day observation period, and 96% (24/25) of the participants submitted messages on at least 5 of the 7 days. Participant characteristics are summarized in Table 1.

Table 1. Participant demographics (N=25).

Characteristics	Values
Sex, n (%)	
Female	17 (68)
Male	8 (32)
Age (y), mean (SD)	62.3 (11.9)
Race, n (%)	
Black or African American	0 (0)
White	25 (100)
Ethnicity, n (%)	
Hispanic or Latino	0 (0)
Non-Hispanic or Latino	25 (100)
Highest educational attainment, n (%)	
High school diploma or equivalent	1 (4)
Technical school, vocational training, or community college	5 (20)
4-year college	8 (32)
Postcollege education	11 (44)
Employment status, n (%)	
Full time	4 (16)
Part time	3 (12)
Not working	4 (16)
Retired	14 (56)
Annual income (US $), n (%)	
<20,000	1 (4)
20,000-39,999	3 (12)
40,000-$59,999	5 (20)
60,000-79,999	6 (24)
80,000-99,999	5 (20)
>100,000	2 (8)
Undisclosed	3 (12)
Length of time managing medications for care recipient (y), mean (SD)	5.0 (3.1)
State of residence, n (%)	
Wisconsin	16 (64)
California	5 (20)
Other	3 (12)
Undisclosed	1 (4)
Care partner's relationship to the care recipient, n (%)	
Adult child or child-in-law	8 (32)
Spouse or significant other	16 (64)
Other (mother and father)	1 (4)
Care recipient's living arrangement, n (%)	
Lives in the primary caregiver's home	20 (80)
Lives in the care recipient's own home	4 (16)
Other (independent living facility)	1 (4)

We derived 3 personas: Checklist Cheryl, in Control; Social Sam, Keeps it Simple; and Responsive Rhonda, Stays Relaxed. These personas varied across 6 dimensions relevant to medication management: approach to medication acquisition and organization, medication administration, monitoring the care recipient for symptoms, communication with the care network regarding medication, and acquiring information about medication. The presentation of the personas given subsequently is organized by their approach to each dimension of medication management, with illustrative examples and quotations from real study participants. Persona profiles are presented in Figure 1.

Figure 1. Three persona profiles representing caregivers' medication management for patients with Alzheimer disease or related dementias.



Checklist Cheryl, in Control

Overview

Checklist Cheryl, in Control, is characterized by her desire to do things on her own, be in control, and create reliable and precise systems and regimens. Cheryl lives in a suite that is separate from but connected to the home of the care recipient, who has late-stage dementia.

Approach to Acquiring and Organizing Medication

Checklist Cheryl has an organized, technology-based system for acquiring and maintaining a constant supply of medications. She sets up automated refills and mail-based delivery for all medications. She organizes medication in an automated medication dispenser, which she fills every 2 weeks. When filling the dispenser, she verifies the dosage in a notebook that describes each medication as well as a large, printed list of the medications with pictures and a description of each that she keeps on the wall for her reference.

Approach to Administering Medication

Checklist Cheryl continuously improved upon her strategies for medication administration and documents the effectiveness of these strategies in a journal. One participant described iterative strategizing to encourage the care recipient to take her medication:

> *[The care recipient] didn't like [taking medication], and she made bad faces. So, I thought, one day I'll just give her something extra. It started, I mean, we've done like Pringles and different types of chips and crackers and all that kind of stuff.* [P1]

Approach to Monitoring for Symptoms

Checklist Cheryl closely monitors the care recipient for symptoms and writes down her observations in a journal to track changes in behavior. She installs a video surveillance system in the care recipient's home to better monitor any symptoms or changes in the care recipient's behavior:

> *If someone goes in the laundry room, it just brings up my cam and app, and then I can just click on the laundry room, and I can quickly look and see who went in there and what they're doing.* [P1]

Approach to Acquiring Medication Information

Checklist Cheryl seeks formal advice about medications. She contacts the care recipient's health care team with medication questions:

> *The medications he's getting now are from the neurologist. So if I see something is wrong, I call the neurologist for changes or advice.* [P7]

Alternatively, Cheryl may do her own research online. Cheryl does not rely on support groups, friends, or family for medication information.

Approach to Communicating With Care Network

Checklist Cheryl was unlikely to ask her formal care team or network of family and friends for help with medication management:

> *I do all of it. And I order [the medications] myself. Hospice said they would order [the care recipient's medications], but I order [the care recipient's medications] at the same time I order my husband's,*

> *so I might as well do it all. I'm kind of a control freak.* [P40]

Technology Use

Checklist Cheryl is a technology expert. Technology is integral to her medication refill system, medication dispenser, information-seeking approach, and the surveillance system she uses to monitor the care recipient's behavior.

Unmet Needs

Checklist Cheryl wants a better system for tracking the care recipient's changing symptoms and side effects over time. She is also unsure when to communicate symptoms or questions to the formal care team versus relying on the answers she can find through her own research. Finally, she finds that medication management is all consuming and leaves little time for self-care, which often leads to stress.

Social Sam, Keeps It Simple

Overview

Social Sam, Keeps it Simple, is characterized by his attributes of being collaborative, seeking efficiency, and valuing the care recipient's independence. Sam and his wife live in the home of the care recipient, who has middle-stage dementia.

Approach to Acquiring and Organizing Medication

Social Sam has a simple system for monitoring and restocking the medication supply. When he sees a pill bottle running low, he places it near his office computer:

> *[The medication bottles] will be right in front of me on top of the, my desk where my computer is...I'll just get on the website and put in the order right then and there.* [P8]

Sam refills an analog medication organizer on the same evening each week. When possible, Sam incorporates the storage of medication into the care recipient's existing routine. For example, one participant described storing inhalers in the care recipient's backpack:

> *When [the care recipient] used to work, he had that backpack with him 100% of the time, and so that's where the inhalers were. And that, I don't want to change that for him.* [P10]

Approach to Administering Medication

Social Sam's routine for administering medication is so consistent that it has become second nature:

> *It's the first thing that I do when I get up...the first thing I do is grab the pill. I also have medication I'm giving the cats, so I grab that at the same time and put it all out on the coffee table, where I keep it during the day.* [P8]

Because Sam values the care recipient's independence, he is subtle when checking whether medication has been taken:

> *I just pretend I'm doing something else and watch [him take the medication].* [P10]

Approach to Monitoring for Symptoms

Social Sam collaborates with his wife, who is also a member of his care network, to monitor the care recipient for symptoms or changes in behavior:

> *One of the things that's happened is [the care recipient] has gotten GERD, probably from all the medication that she's taking, upsetting her stomach. So she's belching more...And so [my wife] and I talk all the time...There's a constant that we check in, how is she? Is that medication bothering her?* [P25]

To monitor the care recipient's pain symptoms, Sam takes weekly glances at the as-needed pain medication bottle to see if there are fewer pills than there were the previous week.

Approach to Acquiring Medication Information and Communication With the Care Network

Social Sam enjoys receiving information and help from others, both clinicians and nonclinicians. For example, he prefers to pick up medications in person so he can ask the pharmacist questions. Sam uses informal sources of medication information, such as support groups and Facebook:

> *I try to draw on everyone and try to get the best information possible to make the right decision.* [P2]

Technology Use

Social Sam is technology proficient. He uses text messaging to communicate with his wife regarding medication management and uses phone reminders to prompt himself to do medication-related tasks.

Unmet Needs

Social Sam finds his current medication refill reminder system to be too simplistic, not accounting for medications with different refill dates. This insufficiently nuanced system results in Sam occasionally forgetting to refill medications and, consequently, missing doses. Though Sam is naturally collaborative, he finds coordinating medication management activities with other family members and formal care team members to be challenging, as he does not like to bother people.

Responsive Rhonda, Stays Relaxed

Overview

Responsive Rhonda, Stays Relaxed, is characterized by the attributes of being laid-back, nonintrusive, and responding to (rather than preparing for) challenges with medication management as they arise. Rhonda lives with the care recipient, who has early-stage dementia.

Approach to Acquiring Medication

Responsive Rhonda responds to overt reminders and alerts to order medication. For example, she may see the medication supply and notice it is low, or she may look into refilling medications when at the pharmacy for other reasons:

> *Like if I'm going in to pick something up in, at the pharmacy, I will just show them his number, his medical number also and just say, hey, is there anything that's available for pickup?* [P10]

Approach to Organizing and Administering Medication

Responsive Rhonda relies on nontechnological cues to remind herself to organize and administer medications. She stores pills where she regularly performs her nighttime routine:

> *The pill is just part of the setup that I do every night, so it's actually not too hard to remember to put that out.* [P9]

As part of existing daytime routine of Rhonda, she walks past the medication she set out and notices if the care recipient has taken the medications or if they need to be reminded.

Approach to Monitoring for Symptoms

Responsive Rhonda does not have a formal system to monitor the care recipient for symptoms, instead relying on intuition:

> *And if I feel like, this is more intuitive, is if I feel like he's [using Tylenol] much more than normal, then that will trigger me to go check on, you know, to ask, dig in a little more about his pain.* [P1]

Rhonda also relies on the care recipient to report symptoms to her.

Approach to Acquiring Medication Information and Communication With the Care Network

Responsive Rhonda is comfortable relying on others in the care network for help, although at this stage in the care recipient's disease, she rarely needs help. When Rhonda is away, she asks other family members to put the medications out for the care recipient and ensure that they take them. Rhonda seldom sees the need for medication information or advice, but when she does have questions, she is comfortable asking the care recipient's care team.

Technology Use

Responsive Rhonda is a technology novice. Although proficient with mobile phone calls, she does not think of incorporating technology into medication management.

Unmet Needs

Responsive Rhonda does not currently perceive any unmet needs related to medication management.

Discussion

Principal Findings

In this study, we leveraged the UCD method of VCI to understand ADRD caregivers' approaches to and needs for medication management. Caregivers exhibited a range of characteristics and values that informed their approach to medication management.

In addition, caregivers used a combination of technology-based strategies and strategies situated in their physical environments to manage medications. However, these personas must be understood with awareness of the relatively homogenous sample, which may limit generalizability. The average caregiver in this study was a retired or unemployed White woman in her 60s, with college or postcollege education, caring for someone in their 70s who lived in her home in the United States. These personas can be used to inform the UCD of interventions for caregivers with similar attributes by enabling designers to build empathy with future users, remain focused on users' needs, and maintain an empirical foundation for design decisions [36,41,42,54]. Specific implications of designing medication management interventions for the described personas are presented in Table 2.

Table 2. Design implications for Checklist Cheryl, Social Sam, and Responsive Rhonda.

Persona	Unmet needs	Example design implications
Checklist Cheryl, In Control	• No system for tracking changing symptoms and side effects over time • Lacks certainty about when to communicate symptoms and side effects to health care professionals • Medication management is all consuming and leaves little time for self-care	• Adaptive tools to track data (symptoms, side-effects, and strategies) and display trends • AIa-powered database that summarizes academic research • Smartphone apps that combine medication management with self-care for caregivers • Bridge to state and federal caregiver grants
Social Sam, Keeps it Simple	• The current reminder system too simplistic, not accounting for different refill dates • Wants more help and advice from family or friends in his care network	• Text- or email-based reminder systems for reordering different medications • Collaborative platforms for distributing medication management across the care network • Social media platforms, virtual support groups, and online forums for obtaining practical and emotional support from caregiver peers
Responsive Rhonda, Stays Relaxed	• No unmet needs perceived, but may emerge as the care recipient's disease progresses	• Printed educational materials about ADRDb and its progression • Analog tools or infographics that she can situate in her environment • A technology broker who can introduce her to digital medication management supports • Bridge to local aging and disability resource centers

[a]AI: artificial intelligence.

[b]ADRD: Alzheimer disease and related dementias.

The specific attributes of each persona build on the existing literature and extend knowledge in the domain of medication management. In a US-based sample of older adults with chronic heart failure, Holden et al [40] identified the rule-following persona, who has the tendency to respond to uncertainty by seeking reliable rules and clinical expertise. In this study, Checklist Cheryl demonstrates how this tendency extends to medication management processes; Cheryl painstakingly triple checks her medication organization, performs elaborate documentation, and does not trust family or friends to assist in medication management, meaning much of the workload falls on her. Caregivers such as Checklist Cheryl would greatly benefit from state or federal grant programs that pay for respite care or in-home nursing [59]. Such programs require support from the policy makers who set funding priorities and establish budgets. Programs such as these would allow Cheryl to construct a formal support network that she can trust to offset her personal workload.

There are few digital health interventions to support medication management for caregivers, such as Checklist Cheryl, in Control, with some exceptions found internationally [60-62]. As a technology expert, Cheryl may benefit from a multicomponent smartphone app that allows her to, first, view medications and their doses and verify if they have been administered correctly. Second, such an app could enable Checklist Cheryl to document and visualize trends over time, including trends in the care recipient's symptoms, medication side effects, and the effectiveness of strategies [63]. Third, because Cheryl is independent and prefers learning from experts over peers, she may benefit from a feature that uses artificial intelligence to answer medication- and dementia-related questions by synthesizing academic literature [64]. Fourth, Checklist Cheryl needs digital assistance with self-care. A recent international systematic review of mobile apps for family caregivers found only 1 app with a self-care feature [65]. Another systematic review of mobile apps with a caregiver and patient focus found that only 15% of apps included a focus on caregiver self-care [66]. Apps that target self-care needs of other types of busy caregivers (eg, new mothers) could be adapted to fit the self-care needs of caregivers of people living with ADRD [67]. While the typical participant in this study was in their early 60s, younger caregivers are more likely to access the internet and use smartphones and thus may be as interested as Cheryl in digital tools for medication management [68]. Digital tools are also likely to have international applications, as over half of the global population owns a smartphone and about one-third of global smartphone owners have used their phone to access health services [69].

Caregivers such as Social Sam, Keeps it Simple, differ from Checklist Cheryl in that they want simple, rather than complex, medication management systems; deemphasize surveillance in favor of promoting the care recipient's independence; and desire collaboration with other network members as opposed to working alone. While Social Sam's current system is designed for efficiency, it is not sufficiently sophisticated to accommodate polypharmacy, which is increasingly common as the disease progresses [26,70]. Caregivers such as Sam are less technology proficient than those such as Cheryl; he has incorporated the web version of the pharmacy website into his medication acquisition process, but has not used smartphone apps. This may be consistent with other caregivers of Sam's age; research affirms that, though only 61% of those who are aged >65 years own a smartphone, 75% of people in this age range use the internet. Technologically proficient caregivers such as Social

Sam may benefit from websites that support reordering and administering medications, for example, through text- or email-based reminders [71,72].

Social Sam finds his network of family and friends to be helpful, leveraging them to monitor side effects and make clinical judgments. However, similar to other caregivers, those represented by Sam find it challenging to ask others for help [73]. Similar to other male caregivers, in particular, the support network of Sam is small [29]. The current landscape of digital tools for caregivers that support peer interaction is limited [66]. Social Sam would benefit from web-based tools that support distributing caregiving work, and specifically medication management, across a caregiving team [74,75]. Furthermore, Sam would benefit from interventions (eg, virtual support groups and social media platforms) that enable caregivers to connect with peers beyond their geographic area. In the United States, technologies that connect caregivers may have even greater uptake among members of racial and ethnic minority groups, who use social media such as Instagram, Reddit, Snapchat, WhatsApp, and TikTok at higher rates [76]. Reliance on caregiving support from family and friends is also greater among ethnic minority caregivers [77]. More broadly, technologies that connect support networks are needed in low- and middle-income countries, where reliance on unpaid support for dementia caregiving is more common [78].

Caregivers in this study who are represented by Responsive Rhonda, Stays Relaxed, differ from both Checklist Cheryl and Social Sam in that they adopt a fundamentally laid-back management style with little systemization. These caregivers await and respond to medication issues rather than proactively anticipating and addressing them. Similar to the disengaging persona by Holden et al [40], Rhonda does not actively seek out medication information or experiment to improve processes. Responsive Rhonda may represent those caregivers of people in the early stages of dementia, who tend to take fewer medications than those in the later stages [26,27]. As the care recipient's disease progresses, Rhonda would likely benefit from caregiver education and training. Those who are caring for someone in the earlier stages of dementia may be relatively disconnected, with healthcare providers as their sole brokers of support; therefore, health care systems can use personas to create tailored discharge instructions for caregivers such as Responsive Rhonda [79].

While she does not currently report unmet needs related to medication management, as the care recipient's medication regimen becomes more complex, Responsive Rhonda may require a more sophisticated system for medication management. The design of such a system should leverage the tendency of Rhonda to distribute cognition to her physical, rather than digital, environment [80-82]. Rhonda represents caregivers who are novice technology users; therefore, suggestions for Rhonda may also apply to less educated caregivers, who may be less likely and less willing to use digital devices (eg, websites and smartphone apps) to support health, according to a sample of Australian adults [83]. Later in the caregiving journey, caregivers such as Rhonda may benefit from printed materials as well as analog tools (eg, medication organizers) that can be placed as convenient cues throughout the home [80,84]. Rhonda may also benefit from a technology broker who can provide training on using technology to support medication management, for example, by introducing her to specific, informative websites or the mobile app of her preferred pharmacy [85]. This recommendation extends to the 38% of the global population who live in areas in which mobile internet is accessible but who do not currently use it [69].

Limitations and Future Directions

Our study had limitations. While our average participant mirrored the typical US caregiver in many ways [86] and the average care recipient's age matched that of many living with ADRD internationally [87], other sociodemographic characteristics were less representative of caregivers. Our participants had, on average, higher educational attainment, which may result in greater health literacy and enhanced medication management as a result [88]. Furthermore, our sample of caregivers was entirely of White individuals. An analysis of Latino caregivers, for example, would have yielded different personas, as Latino caregivers are more likely to be younger, adult children of care recipients and are less likely to live with the care recipient [86]. One US-based systematic review found that Mexican American, African American, and Korean American caregivers are more committed to keeping care recipients at home rather than long-term care facilities, which may result over time in greater caregiver workload [28]. Moreover, our personas reflect only caregivers who have access to and are willing to participate in research projects, and this group may have unique characteristics (eg, connectedness to academic centers and time to participate in research) [40]. Our personas should not be considered representative of all caregivers managing medication but rather a basis on which future investigations may build [89].

These personas are situated between the conception and gestation stages [36]. That is, while our personas reflect important aspects of our data, have been enriched with storytelling, and deepened through stakeholder involvement, they need further refinement before their full implications can be realized. One limitation of these data is that they reflect only 1 week of caregivers' medication management. A next step in deepening these personas is to collect data about medication management over the course of years, rather than 1 week, to reflect how caregivers' needs change with disease progression. Future work could also incorporate caregivers of people whose cognitive status had been objectively assessed rather than reported by caregivers. While research suggests that family member reports of dementia are often accurate and, when inaccurate, err on the side of underreporting dementia [90,91], it would be important to understand any differences in medication management associated with objectively confirmed dementia diagnoses. Finally, this analysis focused on process- and strategy-related differences in medication management among caregivers. Personas could be further deepened by analyses focused on cognitive, social, or clinical dimensions of medication management [39].

Both our data collection method and the use of personas carry a risk of forgoing the nuance in participant experiences. Our data consist of messages submitted by caregivers and

researchers' follow-up inquiries regarding these messages. When data are collected virtually and participants are asked to provide explanations in retrospect, some degree of detail may be lost (though this is curtailed using messages to aid recall) [92]. Furthermore, in VCI, participants are unlikely to submit messages in inopportune moments, meaning there is a delay not seen in traditional contextual inquiry between performing the task and reporting upon it [46]. While virtual observation may curtail observer effects, it is also possible that participants curate a more flattering self-presentation when communicating digitally versus in person [22]. Last, persona creation inherently emphasizes points of distinction rather than similarities across participants [40]. It is likely that many real caregivers possess qualities of more than one of the personas identified in this study or resemble different personas at different points in their caregiving journey.

Conclusions

This study used a novel methodology, VCI, to understand in rich detail how caregivers manage medications on behalf of those living with ADRD. These data were synthesized into user personas that have direct implications for intervention development. For example, smartphone apps that use artificial intelligence to synthesize information about medication management or meaningfully connect caregivers with others who manage medications could support caregivers who value expertise, such as Checklist Cheryl, or collaboration, such as Social Sam. Before the benefit of medication management personas can be fully realized, these personas must be deepened to reflect nuance and expanded to reflect a more diverse group of caregivers and caregiving experiences. These are vital directions for future research. Once personas have matured in this way, they represent a powerful user-centered strategy to test, evaluate, and disseminate technologies that support medication management among ADRD caregivers.

Abstract

Background: In order to address fall underestimation by the *International Classification of Diseases* (*ICD*) in clinical settings, information from clinical notes could be incorporated via natural language processing (NLP) as a possible solution. However, its application to inpatient notes has not been fully investigated.

Objective: This study aims to develop and validate a rule-based NLP algorithm to identify falls based on inpatient admission notes from older patients.

Methods: This retrospective study used 12-year electronic inpatient records of patients aged ≥65 years from public hospitals in Hong Kong. A random sample of 1000 patients was drawn to develop the NLP algorithm. Manual review was the gold standard for assessing the algorithm's performance, with sensitivity, specificity, precision, and F_1-score calculated at the record, episode, and patient levels. In addition, the study compared the number of falls identified by *ICD* codes and clinical notes independently and combined.

Results: Our rule-based NLP algorithm showed excellent performance, with a sensitivity, specificity, precision, and F_1-score of 93.3%, 99.0%, 87.5%, and 0.903 at the record and episode levels, and 92.9%, 98.3%, 89.7%, and 0.912 at the patient level. The combined identification strategy using *ICD* codes and the NLP method provided the most comprehensive capture of fall-related episodes and fallers.

Conclusions: The NLP method proved efficient and accurate in detecting falls from clinical notes in inpatient episodes. For comprehensive capture of fall episodes and fallers, we recommend the combined use of the NLP algorithm and *ICD* codes, which should be applied in future fall epidemiology studies and clinical practice for identifying high-risk groups of fall interventions.

Introduction

Falls are a global public concern and impose considerable health care and economic burdens on the older population [1]. The Decade of Healthy Aging Report from World Health Organization (WHO) highlights fall prevention as an urgent health priority [2]. Fall risk screening is inevitable when identifying vulnerable older individuals for assessment and preventive intervention [3,4]. The history of falls has been widely recognized as a vital component in risk screening [3], given that it doubles the fall risk for older adults [5,6].

In the longitudinal studies on the older population, falls were mainly identified through medical (electronic and nonelectronic) or nonmedical records (eg, retrospective telephone or face-to-face interviews and prospective fall diary or calendar) [6,7]. Compared to nonmedical methods, which are subject to withdrawal or loss of follow-up from participants, medical records are more efficient and cost-saving. Hence, hospitals that provide care for fall-related injuries become the ideal sites to identify and track fallers for interventions. Most studies conducted in clinical settings used the *International Classification of Diseases* (*ICD*) codes to detect falls in the electronic medical records (EMRs) of older adults [6]. Nevertheless, the identification based on the *ICD* codes alone may not completely capture the reported falls. Published studies found that the *International Classification of Diseases, Ninth Revision, Clinical Modification* (*ICD-9-CM*) codes missed 8%

to 20% of falls in patients [8,9]. Involving supplemental records could increase accuracy for fall identification, in which the clinical note review captures the greatest number of events [10]. The traditional manual note review that requires health care professionals as the reviewer is labor-intensive and time-consuming due to the large volume of records. While a relatively expedient and cost-effective approach is searching for the keyword "fall" in the clinical notes, it is important to note that a simple keyword search alone is insufficient to accurately distinguish between fall-related notes and those that do not. This is because notes without actual falls may also contain the term "fall", such as "references to high fall risk," "fall precaution," or "falling asleep," which can result in false positives. To enhance accuracy and overcome this limitation, a novel computer-based approach named natural language processing (NLP) has been applied as an effective solution [11].

NLP algorithms are generally categorized into two approaches: rule based and machine learning (ML) based [11]. While both have their merits, rule-based NLP is selected for this study for several reasons. First, rule-based systems rely on explicitly defined linguistic rules, making them highly interpretable and transparent [12]. This allows developers and users to easily understand and modify the rules, ensuring precise performance. Second, rule-based NLP does not require large annotated datasets, unlike ML-based approaches, which demand extensive training data and computational resource [13]. This makes rule-based systems practical for real-time applications or low-resource environments. Third, rule-based systems efficiently handle edge cases and specific linguistic nuances by directly tailoring rules to unique exceptions—such as distinguishing between actual falls and terms like "falling asleep" in clinical notes—without extensive data or training [12]. While ML-based NLP excels with large-scale datasets and broad contexts [13], it often requires more effort to match the precision and domain-specific adaptability of rule-based systems. In recent years, transformer-based pretrained models have emerged as a powerful ML approach, advancing NLP by capturing long-range dependencies and contextual information in text, even with limited annotated data [14]. Due to their ability to model complex linguistic patterns and contextual relationships, transformer-based models may outperform rule-based systems. Nevertheless, these models still require substantial computational resources, which can be mitigated through cloud-based application programming interfaces (APIs) [15]. In health care systems where patient data confidentiality is strictly restricted, the reliance on internet connectivity to use such models poses a significant challenge. Therefore, for local applications, rule-based approaches remain a pragmatic choice.

However, research on rule-based NLP algorithms for fall identification in clinical notes remains limited. Previous studies have developed rule-based NLP algorithms for inpatient, emergency department (ED), and homecare visit notes [16-18], with the inpatient study specifically focusing on Japanese clinical notes [16]. Although the English-language NLP algorithms for ED and homecare visit notes demonstrated satisfactory performance compared to manual review [17,18], these methods may not be directly transferable to inpatient settings. Hence, more studies are warranted to develop specialized rule-based NLP methods for accurate fall identification in inpatient clinical notes. Furthermore, existing studies primarily compared identification strategies based on single record sources of *ICD* codes or clinical notes [8,9]. There is a lack of studies investigating how the combination of these strategies can enhance fall identification. Therefore, to address these gaps, this study aimed to (1) develop and validate a rule-based NLP algorithm to identify falls based on inpatient admission notes and (2) compare the number of falls identified by independent or combined strategies of *ICD* codes and the NLP method.

Methods

Study Design and Data Source

We performed a retrospective, territory-wide, cohort study using the 12-year (2007-2018) electronic inpatient records of older adults. The dataset used in this study encompasses admissions from all 43 public hospitals of the Hospital Authority (HA), which manage approximately 80% of hospital admissions in Hong Kong and account for nearly 90% of total bed-days [19]. The data were extracted from the Hospital Authority Data Collaboration Lab (HADCL), and the details were described elsewhere [20]. The clinical records were written in English.

Sampling

The sampling frame was a cohort of older adults who (1) resided in Hong Kong, (2) were discharged as an inpatient from public hospitals between January 2007 and December 2017, (3) were aged ≥65 years at admission, (4) had a hospital stay of at least one day for their first inpatient episode, (5) were discharged alive, (6) did not have a hospital discharge from public hospitals 365 days before the first inpatient episode, and (7) were not admitted from the nursing home at their first inpatient episode. More details of the criteria are described elsewhere [20].

To ensure adequate statistical power for developing an NLP algorithm, a sample size of at least 500 is recommended [21]. In this study, a sample of 1000 patients was drawn by random sampling. The electronic clinical notes and diagnosis codes of all inpatient admission episodes from selected patients were extracted for analysis. The dataset contains two types of notes: clinical notes and discharge notes. Only the clinical notes, comprising all textual records associated with linked episodes, were used in this study.

Manual Review

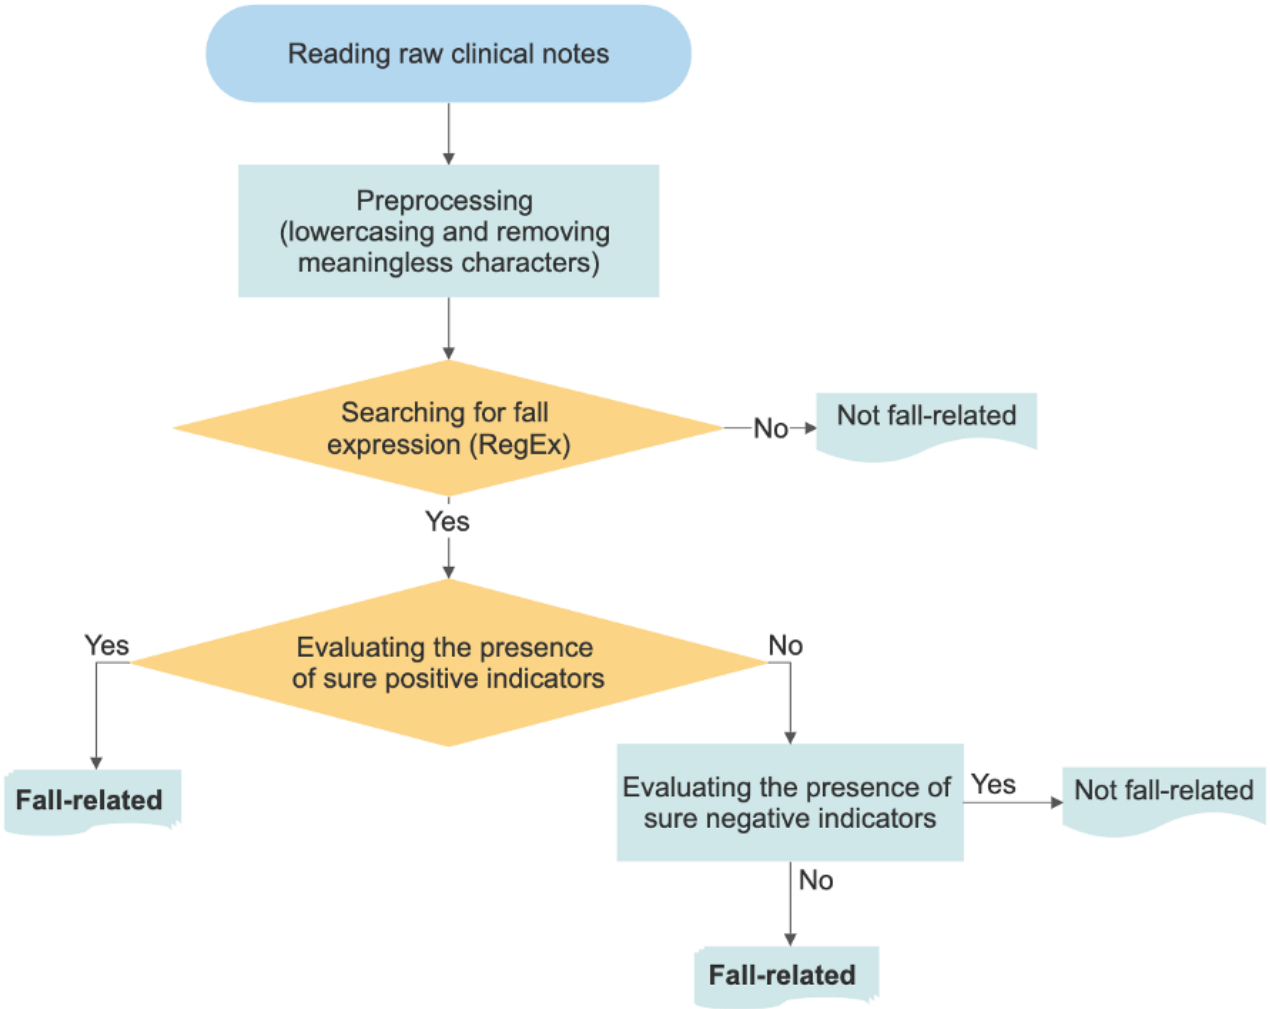
The manual review was considered a gold standard, as consistent with previous studies [16-18]. A total of 2 reviewers independently reviewed each extracted clinical note and determined the corresponding record as being fall related or not, using binary classification. According to the WHO, a fall is defined as an event in which a person unintentionally comes to rest on the ground, floor, or another lower level [1]. An individual who has experienced at least one fall episode is classified as a faller. Reviewers were trained to annotate the clinical notes as fall related if the scenario presented in the notes meet the WHO definition of falls or have specific indicators (eg, "admitted for fall," "presented with fall," "fell onto ground," "slipped and fell," or "fell when..."). Reviewers relied on these

predefined indicators to ensure consistency in their assessments. Any disagreement was resolved by a joint evaluation involving the 2 reviewers and a senior investigator. As each patient could have multiple inpatient admission episodes during the study period and each episode could include multiple records, fall identification was performed at levels of record, episode, and patient. Patients were classified as fallers and episodes were designated as fall related if any associated episodes or records contained falls.

Development and Validation of the Rule-Based NLP Algorithm

Patients were randomly split into the training set for NLP algorithm development and the testing set for validation at a ratio of 80:20 [22]. The development process in the training set included 5 steps (Figure 1). First, clinical notes were preprocessed by lowercasing characters and removing meaningless "Newline Characters" (indicates starting from the next line). Second, the fall expression within the clinical notes was searched by the Regular Expression (RegEx; Section S1 in Multimedia Appendix 1). After filtering out clinical notes with fall expression, the third step evaluated the presence of sure positive indicators (Section S1 in Multimedia Appendix 2) that a fall occurred within the filtered notes. Similarly, the fourth step was evaluating the presence of sure negative indicators (Section S1 in Multimedia Appendix 2) that a fall had not occurred. The sure positive and sure negative indicators were iteratively refined through performance evaluation and rule adjustment. At each cycle, common areas of false positives and negatives were addressed to extend the criteria until the value of sensitivity, specificity, and precision exceeded 90%, and the value of F_1-score exceeded 0.9 at one of the levels for record, episode, or patient [17]. Finally, as fall expression can appear more than once within the same clinical note, the sure positive and negative indicators could coexist in one note. Therefore, clinical notes that (1) had fall expression and (2) had sure positive indicator or did not have sure negative indicator were marked as fall related. Subsequently, the rule-based NLP algorithm was applied to identify falls in clinical notes from the testing set for validation.

Figure 1. Process of the rule-based natural language processing algorithm development. RegEx: Regular Expression.



Comparison of Different Identification Strategies

The number of falls identified by the following methods were compared: (1) manual review of clinical notes, (2) NLP algorithm for clinical notes, (3) *ICD* codes, (4) manual review and *ICD* codes, and (5) NLP algorithm and *ICD* codes. Regarding the strategy of *ICD* codes, a fall was identified by the *ICD-9-CM* E880-E888 for accidental falls or 800 - 909.2,

909.4, 909.9, 910 - 924, 950 - 957, 959 for injury (excluding E000, E800-807, E810-838, E840-858, E860-879, E890-999 for specific external causes of injury) [23,24]. Since not all episodes contain both *ICD* codes and clinical notes—some may lack notes while others may lack *ICD* codes, comprehensive fall identification should consider both data sources. Therefore, the combined strategy, incorporating manual notes review and *ICD* codes, was considered the identification standard to compare the remaining strategies. For combined strategies (4) and (5), the record was identified as fall related when either strategy captured a fall. The comparison was restricted to these 1000 patients, as one of the involved strategies was manual review, which could be time-consuming and labor-intensive if extended to the whole dataset.

Statistical Analysis

The mean and SD values were used to describe the length of clinical notes (number of characters). The falls identified by the developed NLP algorithm were compared with the manual review by confusion matrix to generate standard performance measures of sensitivity, specificity, precision, and F_1-score at the levels of record, episode, and patient in the training and testing sets [25]. Sensitivity refers to the proportion of correctly labeled falls by the NLP algorithm to all falls identified by manual review. Specificity computes the proportion of correctly labeled nonfalls by the NLP algorithm to all nonfalls identified by manual review. Precision reflects the proportion of the correctly labeled falls by the NLP algorithm to all labeled falls by NLP algorithm. F_1-score is the harmonic mean of the precision and sensitivity, with the best value being 1 and the worst being 0. An adequate performance is considered when the value exceeds 90% for sensitivity, specificity, and precision and 0.9 for F_1-score [17]. All data analyses were performed using Python 3.7.6 (CreateSpace).

Ethical Considerations

This study was approved by the Institutional Review Board of the University of Hong Kong and the Hong Kong Hospital Authority West Cluster (approval UW 23 - 046). Informed consent was waived by the Institutional Review Board due to the retrospective, observational nature of the study and the exclusive use of deidentified participant data. Participants were not compensated for their involvement in this study.

Results

In total, 2153 clinical notes (records) of 2095 inpatient admission episodes from 1000 sampled patients were included in the analysis. The mean length of notes was 1072 characters, with an SD of 916. To develop the NLP algorithm, 800 patients (1720 records and 1672 episodes) were randomly assigned to the training set and the remaining 200 patients (433 records and 423 episodes) were assigned to the testing set.

Regarding the training set for development, the manual review identified 140 fall-related records, 135 fall-related episodes, and 127 fallers. In comparison, the NLP algorithm identified 145 fall-related records, 140 fall-related episodes, and 124 fallers. In the testing set for validation, the manual review identified 30 fall-related records, 30 fall-related episodes, and 28 fallers, while the NLP algorithm identified 32 fall-related records, 32 fall-related episodes, and 29 fallers. As shown in Table 1, falls identified by the NLP algorithm were largely concordant with those identified by manual review at record, episode, and patient levels. Performance metrics of the NLP algorithm were satisfactory for both training and testing sets at all 3 levels (Table 2). In the testing set, the NLP algorithm achieved a sensitivity of 93.3%, a specificity of 99.0%, a precision of 87.5%, and an F_1-score of 0.903 at both the record and episode levels. These measures at patient level were 92.9% for sensitivity, 98.3% for specificity, 89.7% for precision, and 0.912 for F_1-score.

Table 3 presents the comparison of different fall identification strategies, with regards to the number of falls identified at the record, episode, and patient levels. Overall, as compared to identification standard of manual notes review combined with *ICD* codes, the NLP algorithm combined with *ICD* codes identified the highest number of falls across all 3 levels (99.4%-104.3%), followed by the NLP algorithm alone (91.1%-93.5%). Specifically, compared to the identification standard, the NLP algorithm combined with *ICD* codes slightly overestimated the numbers of fall-related records and episodes (~4%) yet underestimated the number of fallers (~1%). In contrast, *ICD* codes alone identified the least number of falls (58.7%-60.7%), as 44 inpatient records did not have *ICD-9-CM* codes.

Table . Comparison of fall identification by manual review and the rule-based NLP[a] algorithm.

NLP algorithm and level	Manual review			
	Training set		Testing set	
	Fall, n	Without fall, n	Fall, n	Without fall, n
Record				
Fall	129	16	28	4
Without fall	11	1564	2	399
Episode				
Fall	124	16	28	4
Without fall	11	1521	2	389
Patient				
Fall	116	8	26	3
Without fall	11	665	2	169

[d]In the whole set, 44 records were without *ICD* codes.

Discussion

Principal Findings

This study developed a rule-based NLP algorithm to identify falls in clinical notes of inpatient admission episodes based on a random, territory-wide sample of older patients, which achieved excellent performance when compared with manual notes review in the testing set. We also compared different fall identification strategies, including the use of *ICD* codes or clinical notes alone or in combination. Our findings provide a feasible and efficient solution for fall screening and shed light on future research and practice related to this field in the clinical setting.

Using NLP algorithms to identify falls can significantly reduce the time and human resources required for the manual notes review. Previous studies have developed NLP methods for fall identification in clinical notes of inpatient wards [16,26,27], and the performance of NLP methods varied. Toyabe [16] derived a rule-based NLP algorithm to detect falls in Japanese progress notes and achieved a sensitivity of 100.0% and a specificity of 98.4%, but with a low precision (6.2%) and an F_1-score of 0.118 at the record level. Shiner et al [26] developed

an ML-based NLP method to capture falls in English progress notes, achieving a relatively low sensitivity of 44.1%, a specificity of 97.0%, a precision of 67.2%, and an F_1-score of 0.533 at the record level. Nakatani et al [27] also developed an ML-based NLP algorithm to differentiate fallers and nonfallers in Japanese nursing notes, with a moderate sensitivity of 76.9% and a specificity of 78.5% at the patient level. In this study's testing set, the sensitivity, specificity, precision, and F_1-score of the rule-based NLP algorithm were 93.3%, 99.0%, 87.5%, and 0.903 at the record level and 92.9%, 98.3%, 89.7%, and 0.912 at the patient level, respectively. The values of these measures were generally higher than previous studies, indicating the promising performance of our rule-based NLP algorithm. Notably, our NLP method was rule based and could be easily applied by researchers or health care professionals with limited programming knowledge to facilitate fall identification in inpatient settings. The rule-based NLP algorithm is also flexible for adjustment based on the different patterns of clinical notes and could be generalized to different systems, such as the ED clinical notes. In addition, future studies may explore the extended application of the NLP method in extracting other fall-related information, such as the circumstance of falls, the mechanism of falls, and resulting injuries, which are important in informing the prognosis and required interventions for patients who have experienced falls [3].

In the epidemiological studies for falls in older adults, the number of fall episodes and fallers are typically the outcomes of interest in estimating the risk (eg, incidence and proportions) and associations. Our findings suggest that the fall identification strategy involving *ICD* codes and clinical notes provides the most comprehensive capture of fall-related episodes and fallers. Identification of falls based on *ICD* codes alone is known to underestimate the number of falls [8,9,28]. Incorporating information from clinical notes is especially beneficial in addressing this issue. Given the limitations of manual review, the NLP algorithm offers an efficient way for applying the combined strategies of clinical notes and *ICD* codes in fall identification on a large scale. Our study found that compared with the combination of manual review and *ICD* codes, the combination of NLP algorithm and *ICD* codes slightly overestimated the number of fall-related episodes (~4%) but not the number of fallers. Therefore, the fall identification strategy combining NLP algorithm and *ICD* codes with feasibility and accuracy has promising application value in risk screening and patient tracking.

The health care workforce shortage is a global problem. Identification of efficient methods to enhance the quality of patient care and safety is a priority agenda in health care field. In terms of implications to practice, there are posthospital health care services or fall prevention programs designed to improve functions and reduce falls for patients recently discharged from hospitals. Fall history is a dominant risk factor for posthospital falls in older patients [6]. Since hospitals are ideal sites for identifying and tracking patients with a history of falls, this combined strategy of NLP method and *ICD* codes is expected to benefit posthospital fall interventions both at baseline and during follow-up. The combined strategy allows for standardized and consistent screening across an extensive EMR dataset, and it can be integrated into existing EMR systems to conduct real-time screening and identification of fall events within minutes. For instance, upon discharge, health care professionals can use it to screen older patients with a history of falls to be recruited in posthospital fall prevention programs. After discharge, patients' fall-related readmission can be tracked and identified timely by this strategy in the EMR system. To establish a more comprehensive surveillance procedure, supplementing nonmedical methods to collect fall incidents that do not present hospitals can be considered. Meanwhile, posthospital health care services, such as the Nurse and Allied Health Clinic (NAHC) for Falls, are designed specifically to prevent falls for patients. Especially for a resource-limited setting, such services can better target patients with a fall history.

The strengths of this study include using 12-year medical records from a territory-wide older population across multiple hospitals, which enhances the reliability and generalizability of the developed NLP algorithm. In addition, we compared the performance of independent and combined fall identification strategies based on *ICD* codes and clinical notes to determine the optimal method in practice. However, several limitations should be acknowledged. First, direct comparison of our NLP algorithm with existing rule-based and ML-based NLP algorithms, including transformer-based pretrained models, was not conducted in this study. Future research should compare the performance of these approaches on the same set of inpatient notes and evaluate their strengths and limitations. Second, a comprehensive analysis of false positives and negatives pattern could not be presented due to data sharing restrictions. Third, due to data availability, this study was limited by the inability to incorporate clinical notes from patients admitted to the ED to derive and compare NLP algorithms for different health care utilizations. Future studies are warranted to compare NLP methods generated from different settings and evaluate their contribution to fall identification. In addition, since the data in this study were drawn from 12-year medical records, it is uncertain whether the writing style of doctors or nurses changed over time. The lack of interrater reliability testing represents another limitation of this study. While the analysis of performance metrics for *ICD* codes would provide a more comprehensive comparison, this analysis was not conducted in this study and remains an important direction for future research. Finally, this study used a cohort developed for another study, which excluded older patients who had hospitalizations within the past year or were admitted from nursing homes, leading to a relatively healthier sample with lower fall risk. Investigations on the performance of our rule-based NLP algorithm in a more general older population are required.

Conclusions

To conclude, this study has demonstrated that the rule-based NLP algorithm could efficiently and accurately detect falls in clinical notes from inpatient admission episodes with excellent performance. The combined identification strategy that incorporates the NLP algorithm and *ICD* codes could be applied to comprehensively capture fall episodes and fallers in future research of fall epidemiology, as well as in clinical practice to facilitate the identification of high-risk groups for fall interventions.

Abstract

Background: Falls are the leading cause of injury among older adults, with vision impairment recognized as a significant risk factor. However, many existing studies have been limited by small sample sizes, retrospective designs, or insufficient adjustment for confounding factors. To overcome these limitations, we used data from the University of Michigan's Health and Retirement Study (HRS) to analyze the association between self-reported vision and fall risk among older adults in a large, nationally representative sample.

Objective: The objective of this study was to investigate the association between vision impairment and falls and assess whether subjective vision impairment predicts future falls in older adults.

Methods: This cross-sectional and longitudinal analysis used data from the HRS (1996 - 2020) to assess the relationship between self-reported vision, glaucoma history, and falls among US adults aged 65 years and older. HRS uses a biennial, multistage area probability sample survey design, collecting data with community-dwelling individuals followed up every 2 years until death, tracking health, economic, and social outcomes. Multivariate logistic regression was used to analyze associations between self-reported vision and self-reported falls in the past 2 years.

Results: A total of 38,835 respondents contributed 117,834 observations. The weighted proportion of participants reporting falls was 37.9% (95% CI 37.7% - 40.1%). Significant risk factors for falls included overall eyesight impairment (adjusted odds ratio [aOR] 1.36, 95% CI 1.20 - 1.56), distance vision impairment (aOR 1.37, 95% CI 1.32 - 1.42), near vision impairment (aOR 1.33, 95% CI 1.27 - 1.37), and glaucoma (aOR 1.15, 95% CI 1.07 - 1.24). A similar association was observed for serious falls, where overall eyesight impairment (aOR 1.20, 95% CI 1.03 - 1.44), distance vision impairment (aOR 1.14, 95% CI 1.07 - 1.22), near vision impairment (aOR 1.12, 95% CI 1.05 - 1.18), and glaucoma (aOR 1.15, 95% CI 1.05 - 1.26) were significant. In longitudinal analyses, overall vision impairment (aOR 1.23, 95% CI 1.16 - 1.29), distance vision impairment (aOR 1.27, 95% CI 1.20 - 1.38), near vision impairment (aOR 1.23, 95% CI 1.19 - 1.32), and glaucoma (aOR 1.25, 95% CI 1.13 - 1.37) increased the risk of future falls. Reported overall vision was significantly associated with the number of falls in both the same (P<.001) and subsequent (P<.001) survey cycles.

Conclusions: Both distance and near vision impairment, as well as glaucoma, are associated with a higher risk of falls in older adults and present possible areas for intervention and prevention.

elderly; falls; glaucoma; Health and Retirement Study; vision impairment

Introduction

Falls are the leading cause of injury among adults ages 65 years or older [1]. Nearly 30% of older adults fall each year, and 10% report injury from a fall [2]. In the United States in 2018, there were 36 million reported falls, resulting in 3 million emergency department visits, nearly 1 million hospitalizations, and 32,000 deaths [3]. Approximately 1 in 10 falls in older adults results in serious injury, such as hip fracture or traumatic brain injury, and the annual cost of falls in the United States is more than US $50 billion [4-6]. Globally, falls are the 13th leading cause of death, and the prevalence of falls is increasing as the

population gets older [7]. Fortunately, multifactorial intervention strategies such as medical staff and patient education, providing supplies for hip protection, and sensory optimization by providing hearing aids have all been able to successfully reduce the risk of falling [5,7,8]. Home modifications to improve safety, such as changing floor coverings, removing loose carpets, fitting handrails, maintaining steps and ramps, and improving lighting, can reduce falling hazards in homes.

Falls are significant, life-altering health events with modifiable risk factors such as impaired balance, polypharmacy, and poor vision [9-11]. Impaired vision has been shown to be a risk factor for falls in older adults. In 1998, the Beaver Dam Eye Study showed that impaired visual acuity was associated with an increased risk of falling, and older adults in the worst visual acuity group were significantly more likely to have fallen 2 or more times in the past year [12]. The Blue Mountains Eye Study similarly found a significant relationship between low visual acuity and falls. In addition, they reported that decreased contrast sensitivity and reduced visual field (VF) increased the risk of falls and proposed that the presence of a cataract may explain this association [13]. In the Salisbury Eye Evaluation study, only reduced peripheral VF was associated with the risk of falling, while visual acuity, contrast sensitivity, and stereo acuity were not after adjusting for potential confounders [14]. Other studies support a relationship between impaired vision and falls but differ as to which components of visual function increase fall risk [5,9,15-17].

These studies provided valuable information that broadly supports impaired vision as a modifiable risk factor for falls; however, many of these studies had limitations due to small sample sizes, retrospective analyses, or the inability to adjust for confounders. Even the most extensive studies to date have data spanning only 1 - 2 years and are generally limited to local communities or geographic regions [12-14].

To address these limitations, we used the University of Michigan Health and Retirement Study (HRS) data. The HRS is a diverse, nationally representative longitudinal panel study of US adults ages 50 years and older, followed every 2 years for over 20 years [18]. Data on fall incidence and self-reported vision impairment were collected from over 25,000 respondents over a period of two decades. [7]. Self-reported vision has been established as a practical proxy measure for visual function, demonstrating a strong relationship with various objective visual function assessments [19,20]. This indicates that self-reported vision can serve as a reliable indicator of visual acuity. Furthermore, self-reported vision assessments offer a valuable advantage in under-resourced areas, where accessible and convenient tools for vision evaluation are scarce. By leveraging self-reported vision data, researchers and health care professionals can overcome logistical barriers and better understand vision-related needs in these communities. A better understanding of what aspects of vision impairment increase fall risk will help clarify promising vision interventions to decrease the rate of falls among older adults.

The objective of this study was to investigate the relationship between various aspects of self-reported vision impairment and falls and prospectively assess whether subjective vision impairment is predictive of future falls in a large and diverse longitudinal population-based study of older adults.

Methods

Data Collection

Data were from the HRS database, a longitudinal panel study that surveys a nationally representative sample of Americans aged 50 years and older every two years, with follow-up continuing until death. The HRS uses a biennial, multistage area probability sample survey design, using a combination of in-person and telephone interviews to collect data. The survey focuses on community-dwelling individuals. This longitudinal design enables the tracking of participants' health, economic, and social outcomes over time, providing a comprehensive understanding of aging and retirement in America. The HRS is supported by the National Institute on Aging (NIA U01AG009740) and the Social Security Administration. For this study, we used data from 14 waves of the HRS (1996 - 2020).

The analytic subsample for this study comprises community-dwelling respondents aged 65 years and older from the 1996 - 2020 HRS survey rounds, as the falls questionnaire was only administered to participants at or older than this age threshold, with all included variables having item nonresponse rates below 10%.

Ethical Considerations

Since the HRS database is deidentified and publicly accessible, this study was exempt from the Mass General Brigham institutional review board approval and patient permission was waived. The study adhered to the tenets of the Declaration of Helsinki.

Primary Outcomes and Definitions of Variables

The primary outcome measures included self-reported falls, serious injury falls, and the number of falls. Participants were asked if they had fallen in the past two years. If they answered "yes," they were then asked how many times they had fallen and whether any of the falls were serious. Serious injury falls were defined as those requiring medical treatment.

Ophthalmic parameters were acquired from the HRS survey assessments and included overall eyesight, distance vision, and near vision (see Multimedia Appendix 1), each rated on a scale from 1 to 5, with scores of 4 (fair) and 5 (poor) considered indicative of impaired vision. For overall eyesight, a score of 6 could be assigned for patients with legal blindness. The history of glaucoma was based on whether participants reported ever being treated for glaucoma.

The HRS also collected information on age, gender, race, level of education, marital status, self-reported diagnoses of hypertension, diabetes, stroke, heart conditions (including heart attack, coronary heart disease, angina, congestive heart failure, or other heart problems), arthritis or rheumatism, smoking and alcohol consumption status, psychiatric medication use, exercise activities, and household income.

Study Timepoints of Data Analysis

The data were analyzed cross-sectionally and longitudinally to confirm the correlations between ophthalmic parameters and falls. Each participant observation was analyzed as individual encounters in both analyses. In the cross-sectional analysis, self-reported ophthalmic parameters and falls were ascertained from the same 2-year interview cycle. Each completed survey was counted as 1 entry. In the longitudinal analysis, the self-reported ophthalmic parameters were obtained during the survey and analyzed with the reported falls recorded in the patient's survey 2 years later.

Statistical Analysis

Data are presented as base-year weighted proportions, accounting for the Health and Retirement Study adjustments for attrition and sampling error. Descriptive statistics were used to summarize participant data on falls outcomes, including falls, no falls, serious falls, and nonserious falls. We used *t* tests for continuous variables and χ^2 tests for categorical variables to evaluate differences between outcomes. We used univariable and multivariable logistic regression models to determine the cross-sectional and longitudinal association between ophthalmic parameters and falls, adjusting for age and other potential confounders by calculating the odds ratio (OR) and their corresponding 95% CI. For the cross-sectional model, we assessed the association between vision status and reported falls in the same 2-year survey cycle, while for the longitudinal model, we considered falls reported in the subsequent 2-year survey cycle.

All variables with a *P* value of <.05 in the univariable analyses (including age, sex, Hispanic ethnicity, race, education, marital status, hypertension, diabetes, heart disease, stroke, arthritis, smoking, alcohol status, psychiatric medications, degree of exercise, and household income) were included in multivariable logistic regression models. Separate multivariable regression models were used to determine the relationship between each ophthalmic parameter and falls and serious falls. In addition, the association between the degree of vision impairment and the number of falls was assessed using a 1-way analysis of variance. All models were analyzed using generalized estimating equations for multiple observations from the same participant and multiple imputation techniques to replace the missing data. Data analysis was done with IBM SPSS Statistics 22.0 for Microsoft Windows and *P* values <.05 were considered statistically significant.

Results

Demographics of Study Sample

A total of 38,835 respondents contributed to 117,834 participant-observations (see Tables 1 and 2). The total number of observations in which participants reported a total of 40,477 falls and 13,471 serious falls. The weighted proportion of participants who reported any falls was OR 37.9% (95% CI 37.7% - 40.1%), while the proportion reporting serious falls was OR 30.9% (95% CI 30.7% - 31.1%). Furthermore, the weighted proportion of participants who experienced falls in the future was OR 36.5% (95% CI 35.8% - 37.2%), and OR 32.5% (95% CI 32.2% - 32.9%) for future serious falls. Falls increased with older age, and over half of those aged 90 years and older reported falling. The proportion of falls qualifying as serious also increased with age. White people had the highest fall rate, and a higher proportion of falls and serious falls was observed in females and individuals with lower levels of education. In total, 50% of patients with a history of stroke reported falling, with one-third of the falls being serious falls.

Ophthalmic Parameters and Falls

Higher rates of any type of falls and serious falls were observed with worse eyesight (see Tables 3 and 4). Approximately half of the participants who reported poor vision or blindness also reported falling, while 42.8% (95% CI 38.3% - 46.7%) of those with blindness had serious injuries associated with the fall. Of the participants with poor distant and near vision, 53.2% (95% CI 52.7% - 54.1%) and 50.2% (95% CI 49.9% - 50.6%) reported falls, respectively, and over a third of the falls were serious. In addition, falls were reported by 39.6% (95% CI 38.8% - 40.5%) of those who stated they had glaucoma.

Cross-Sectional Analysis

Cross-sectionally, vision impairment was associated with higher odds of falls: impaired overall eyesight (aOR 1.36, 95% CI 1.20 - 1.56; *P*<.001), impaired distance vision (aOR 1.37, 95% CI 1.32 - 1.42; *P*<.001), and impaired near vision (aOR 1.33, 95% CI 1.27 - 1.37; *P*<.001) all conferred significantly increased odds of falls after adjusting for confounding factors (see Table 5 and Figure 1). The odds of serious falls increased in impaired overall eyesight with adjusted ORs of 1.20 (95% CI 1.03 - 1.44; *P*<.001), while having overall eyesight qualifying as legal blindness increased the odds of falls (aOR 1.32, 95% CI 1.26 - 1.37; *P*<.001) and serious falls (aOR 1.16, 95% CI 1.03 - 1.21; *P*<.001) compared to not having impaired vision. Self-reported glaucoma increased the adjusted odds of falls (aOR 1.15, 95% CI 1.07 - 1.24; *P*<.001) and serious falls (aOR 1.15, 95% CI 1.05 - 1.26; *P*<.001).

Longitudinal Analysis

In the longitudinal analysis of the association between ophthalmic parameters with falls and serious falls, impaired overall eyesight, impaired distance vision, impaired near vision, and self-reported glaucoma all increased the odds of future falls with an OR of 1.23 (95% CI 1.16 - 1.29; *P*<.001), 1.27 (95% CI 1.20 - 1.38; *P*<.001), 1.23 (95% CI 1.19 - 1.32; *P*<.001), and 1.25 (95% CI 1.13 - 1.37; *P*<.001), respectively (see Table 6 and Figure 2). Impaired overall eyesight, distance vision, and near vision also increased the risk of serious falls in the subsequent 2 years with an OR of 1.18 (95% CI 1.05 - 1.23; *P*<.001), 1.13 (95% CI 1.04 - 1.21; *P*<.001), and 1.15 (95% CI 1.07 - 1.22; *P*<.001), respectively. There was no association between self-reported glaucoma and the odds of future serious falls (*P*=.32).

Analysis Between Mean Number of Falls and Eyesight

The mean number of falls was associated with the degree of self-reported vision impairment (see Table 7). The level of eyesight reported in the questionnaire was associated with the reported number of falls in the same survey cycle as well as the subsequent cycle (P<.001 for both). Approximately 2.57 (SD 4.58) falls per person who fell were observed in the group with excellent current eyesight compared to 3.70 (SD 5.33) for those with poor reported vision. Similarly, self-reported excellent overall eyesight had an average of 2.78 (SD 4.17) falls per person while poor overall eyesight had approximately 3.65 (SD 5.40) falls per person in the subsequent cycle.

Table . The association of the degree of visual impairment and mean number of falls.

Degree of impairment	Excellent	Very good	Good	Fair	Poor	*P* value
Cross-sectional, mean (SD)						
Overall eyesight	2.57 (4.58)	2.58 (3.84)	2.74 (4.05)	3.15 (4.59)	3.70 (5.33)	<.001
Distal eyesight	2.66 (4.16)	2.70 (4.04)	2.79 (4.05)	3.34 (4.94)	3.73 (5.26)	<.001
Near eyesight	2.59 (3.86)	2.65 (4.23)	2.77 (4.04)	3.2 (4.52)	3.88 (5.79)	<.001
Longitudinal, mean (SD)						
Overall eyesight	2.78 (4.17)	2.71 (4.10)	2.84 (4.18)	3.19 (4.72)	3.65 (5.40)	<.001
Distal eyesight	2.74 (4.13)	2.75 (3.95)	2.93 (4.40)	3.27 (4.89)	3.59 (5.08)	<.001
Near eyesight	2.66 (3.92)	2.72 (4.01)	2.91 (4.37)	3.28 (4.92)	3.62 (5.10)	<.001

Discussion

Principal Findings

In this large and diverse longitudinal population-based study of older adults, poor vision, including both distance and near vision, increased the odds of falling, and more severe vision loss was related to the number of falls. We additionally found that the presence of self-reported glaucoma was associated with falls.

Comparison With Previous Studies

Many population-based studies have found associations between self-reported vision impairment and falls. The Survey of Health, Ageing, and Retirement in Europe (SHARE) study found that self-reported distance and near vision impairment were cross-sectionally and longitudinally associated with increased risk of falls [21]. The Beaver Dam Eye Study reported that people with worse binocular acuity had higher odds of 2 or more falls [12], while the EPIC-Norfolk eye study found significant associations between poor self-reported distance vision and falls

independent of visual acuity [20]. Similarly, we demonstrate here that the presence of visual impairment, including overall eyesight, near vision, and distance vision, is all associated with significantly increased odds for falls and severe falls in both our cross-sectional and longitudinal analyses. Our results suggest that self-reported visual status is predictive of falls and serious falls.

Importantly, the degree of self-reported visual impairment was associated with the number of falls even after adjusting for potential confounders. When looking at the mean number of falls that occur per person for each level of reported vision, we found that though people with excellent vision had falls, the number increased significantly as vision worsened, with those with blindness having the highest risk of falls. This is true for both falls that occurred 2 years before and those that occurred in the following 2 years of the reported vision and does not take into account the fact that blindness likely reduces the number of steps taken.

This study also subclassified falls as serious based on whether a fall had any associated injuries requiring medical treatment. The incidence of serious falls increased with age and deterioration of eyesight, and we found the risk factors for falls and serious falls to be similar. Other studies, including a Finnish population-based study, have examined risk factors of major injurious falls and similarly found poor distant visual acuity to be a risk factor for major falls among disabled elder adults [22].

Visual input plays a critical role in coordinating and planning movement, as well as maintaining balance [23]. Individuals with poor vision are more likely to lose stability, alter their gait to avoid obstacles, and ultimately increase their risk of slips, trips, and falls [24]. Our study differs from previous research in this area, which has largely relied on data from previous falls and visual function assessments. By using self-reported data, our research offers a fresh perspective and highlights the potential of self-reported visual function data as a predictive tool for falls risk.

We also found that glaucoma is a risk factor for serious falls resulting in injury despite the fact that our definition of glaucoma was imperfect (based on self-report only). Any nondifferential misclassification in diagnosing glaucoma would have driven our associations toward the null, and this implies that the associations found were real and may have been underestimated. Previous studies have also reported glaucoma as an independent risk factor for falling [13]. Glaucoma severity has been reported as a risk factor for falls, with advanced glaucoma patients having the highest risk of falls compared to controls with no glaucoma and mild or moderate glaucoma [25]. While central vision and, therefore, visual acuity are often preserved in glaucoma until severe stages of disease, glaucoma patients experience changes in multiple other aspects of vision, including VF loss, decrease in contrast sensitivity, and loss of depth perception. All these visual measures have been shown to independently increase the risk of falling [13,14,26]. Indeed, the Salisbury Eye Evaluation found that loss in peripheral VF is a more important risk factor for falls than loss of central VF [14]. Patients with glaucoma may experience one or all visual deficits simultaneously, further increasing the risk of falling.

Studies have suggested various interventions to reduce the risk of falls, including mobility training, vision interventions to improve vision (eye examinations, cataract surgery, and prescription glasses) [27], risk factor assessment, and environmental modifications to make living environment less hazardous [28]. Visual impairment leads to physical impairment of mobility and balance control, increasing the risk of falls [29]. Glaucoma initially affects peripheral vision through retinal nerve fiber layer loss, which is associated with decreased postural stability; therefore, glaucoma patients may benefit from mobility training to reduce falling risks [30,31].

Clinical Implications

Our results provide evidence to support the development of multifaceted fall prevention strategies. Specifically, our findings suggest that self-reported vision screening could be a valuable tool in identifying individuals at risk of falls. This screening could be easily integrated into telemedicine platforms or incorporated into standard clinical guidelines. Furthermore, we propose the development of a simple, score-based questionnaire that can be used to predict falls risk in older adults. Those with higher scores could be targeted for earlier intervention, thereby reducing their risk of falls.

Limitations

There were several limitations to our study. All data used in this study were from self-reported questionnaires administered every 2 years and are susceptible to recall bias and recall error. Specifically, participants may have difficulty recalling their visual function or falls history, which could lead to inaccurate reporting. In addition, while self-reported visual function has been shown to correlate closely with objective visual function, it is also understood as a multidimensional measure that reflects some, but not all components of vision [19]. Since no eye examinations were done and objective visual function was not measured, we cannot determine which visual components contributed to participants' self-reported visual function. This study is also limited by the specific questions collected as part of the HRS study. No questions were asked about the other leading causes of blindness and visual impairment in this older adult population, such as age-related macular degeneration and other neurological conditions that could affect falls, such as Parkinson disease, dementia, or epilepsy. Finally, we could not explore other known vision-related risk factors for falls such as contrast sensitivity, VF deterioration, depth perception, and stereoacuity [26]. Nonvision factors such as cognitive ability, balance, motor control, and degree of mobility, which are known to be associated with falls, were not evaluated since they were not included in the questionnaire. The omission of these factors may limit the generalizability of our findings and highlights the need for future studies to incorporate a more comprehensive set of measures.

Conclusions

Our analysis of data from a large, longitudinal national survey of older adults demonstrated that vision-related risk factors, particularly the presence and degree of visual impairment and glaucoma, increase the rate of falls and serious falls. We additionally show that self-reported vision status correlates with

the number of fall events both at the time of and occurring after the survey date. Our results support screening for the presence of visual impairment and signs of glaucoma in older adults to identify individuals at the highest risk of falling who might most benefit from fall prevention interventions.

Abstract

Background: Injuries from falls are a major concern among older adults. Targeted exercise has been shown to improve fall risk, and recommendations for identifying and referring older adults for exercise-based interventions exist. However, even when very inexpensive or free, many do not use available fall prevention programs, citing barriers related to convenience and safety. These issues are even greater among older adults residing in rural areas where facilities are less abundant. These realities highlight the need for different approaches to reducing falls in novel ways that increase reach and are safe and effective. Web-based delivery of exercise interventions offers some exciting and enticing prospects.

Objective: Our objective was to assess the efficacy of the Strong Foundations exercise program to change markers of physical function, posture, balance, strength, and fall risk.

Methods: Strong Foundations is a once weekly (60 minutes), 12-week iterative program with 3 core components: postural alignment and control, balance and mobility, and muscular strength and power. We used a quasi-experimental design to determine changes in physical function specific to balance, postural control, and muscular strength among older adults at low or moderate risk of falling.

Results: A total of 55 low-risk and 37 moderate-risk participants were recruited. Participants significantly improved on the 30-second Chair Stand (mean change of 1, SD 3.3 repetitions; P=.006) and Timed Up and Go (mean change of 0.2, SD 0.7 seconds; P=.004), with the moderate-risk group generally improving to a greater degree than the low-risk group. Additionally, Short Physical Performance Battery performance improved significantly in the moderate-risk category (P=.02). The majority of postural measures showed statistically significant improvement for both groups (P<.05). Measures of “relaxed” posture showed improvements between 6% and 27%. When an “as tall as possible” posture was adopted, improvements were ~36%.

Conclusions: In this 12-week, iterative, web-based program, we found older adults experienced improvement not only in measures used in clinical contexts, such as the 30-second Chair Stand and Timed Up and Go, but also contextualized gains by providing deeper phenotypical measurement related to posture, strength, and balance. Further, many of the physical improvements were attenuated by baseline fall risk level, with those with the highest level of risk having the greater gains, and, thus, the most benefit from such interventions.

Introduction

The absolute number of adults older than 65 years of age has been steadily growing for decades and now outnumbers the number of children younger than 18 years of age [1]. In addition, estimates indicate that older adults will represent greater than 23% of the population in the United States by 2035 [1]. Injuries resulting from falls are the largest cause of accidental death and mobility-related disability among older adults. This is likely because nearly one-quarter of community-residing adults older than 65 years of age fall annually, and that number rises to almost half of those older than 80 years of age [2]. Particularly concerning is the fact that once an individual starts to fall, there are often additional falls. Indeed, evidence from numerous sources suggests that between 10% and 44% of older adult patients who have fallen will sustain additional falls in the following year [3-7].

Targeted strength and balance exercises have consistently been shown to improve fall risk, and accordingly, recommendations for identifying and referring older adults for exercise-based interventions have been developed. Public health and clinically oriented authorities, including the Centers for Disease Control and Prevention (CDC) and the US Preventive Services Task Force, have acknowledged the importance of risk assessment and physical activity (PA) in improving fall risk for older adults. The CDC's Stopping Elderly Accidents and Deaths Initiative (STEADI) has also established an evidenced-based questionnaire that assesses known risk factors to help clinicians stratify individuals by risk category to identify those who should be best served by fall prevention programs [8-10].

Many exercise programs for older adults exist. While some health insurance may include access to programs such as Silver Sneakers and EnhanceFitness PA at no additional charge [11], many older adults may have to pay substantial fees to participate. Further, even when very inexpensive or free, many eligible older adults do not use these programs, citing several barriers [11,12]. These include personal preferences (dislike of gymnasiums and lack of knowledge regarding appropriate activity), environmental factors (difficulty in reaching gymnasiums or classes, concerns about bad weather and driving, concerns about being "old" in a gymnasium environment), and structural factors (limited number of facilities and concerns about instructor expertise with older adults) [12]. These issues are even greater among older adults residing in rural areas. Rural residents have fewer facilities for guided PA, more limited transportation infrastructure [13], and less exercise expertise than their urban counterparts [14]. Confounding these difficulties, ongoing concerns exist surrounding the COVID-19 transmissibility alongside the availability, and desirability, of in-person programs. Since the height of the pandemic, there has been a growth in available options for in-person exercise programs. However, while vaccines and exposure have decreased the likelihood of serious infection, there remains some risk associated with (large) in-person gatherings, particularly among the more vulnerable older adult population.

These realities highlight the need for different approaches in addressing the public health challenge of reducing the likelihood of falls in older adults in novel ways that increase reach and are safe and effective. Digital delivery of exercise interventions offers some exciting and enticing prospects, as not only can this platform eliminate barriers related to difficulty with transportation and concerns about the gymnasium environment, but it can also bring highly qualified experts to individuals who are the most in need. These include those experiencing specific conditions that require special instruction and those living in rural and geographically remote areas. Given that older adults are increasingly confident and competent using the internet and videoconferencing tools [15,16], developing interventions that leverage this technology to improve access to fall-risk reduction exercise programs, including balance, posture, and strength training, is both worthwhile and feasible.

Despite these possibilities, there remains limited research on digital group–based exercise programs, particularly those focused on fall prevention. Further, the available evidence is generally drawn from relatively small samples [17-19], or the studies have been conducted in populations with specific medical conditions or comorbidities such as diabetes [20,21] or mild cognitive impairment [22]. To the authors' knowledge, there are only 2 randomized studies with a sample size greater than 20 that have focused on healthy older adults. Although the exercise modalities differed, following the intervention, participants did have generally positive findings regarding improvements in strength and balance [23,24]. However, neither intervention included exercises specific to postural control, a factor strongly hypothesized to influence fall risk [25,26]. Moreover, instruction during exercise sessions in nearly all studies we reviewed, regardless of the health status of the participants, was generalized to the entire class due to the difficulty of the instructor speaking to any 1 person to correct technique without interrupting the flow of the class.

Therefore, we developed and digitally deployed an evidence-based exercise program, Strong Foundations (SF), with instruction provided in real time, to enhance physical function and ultimately prevent falls among older adults. The aim of this study was to evaluate the SF program's effectiveness in improving the posture, balance, and strength of older adults using valid, reliable, and widely used measures of physical function.

Methods

Ethical Considerations

This study was approved by the institutional review board (#806696) at the University of California, San Diego, and informed consent was gathered from all participants. They were further informed that they did not have to complete any measurements and were free to withdraw from the exercise sessions at any time. Participants were additionally provided with US $20 for each laboratory visit to cover travel costs and were given resistance bands to be used during the exercise

intervention (value ~US $10). All data were de-identified prior to analyses with a code to participant numbers and identities held only by the PI and study coordinator and maintained in protected file servers.

Study Design and Recruitment

We used a quasi-experimental design to determine the efficacy of digitally delivered exercise for improving physical function specific to balance, postural control, and muscular strength among older adults at low or moderate risk of falling. Several strategies were used to recruit participants: (1) posters displayed at older adult living facilities and community centers; (2) emails sent to existing lists of older adults who previously expressed interest in research studies in general, and in fracture prevention, specifically; and (3) announcements made following educational presentations on fall and fracture prevention delivered digitally or in person to various groups of older adults in the community. Those who expressed interest were contacted by study personnel and screened by phone for eligibility. Inclusion criteria included being 60 years and older, having an internet-enabled device with a screen of 7+ inches (tablet, laptop, or similar), and scoring less than 8 on the CDC's STEADI questionnaire. Participants were further stratified based on their answers to the STEADI questionnaire into low- and moderate-risk groups with a maximal score of 3 and 7, respectively [27].

Intervention Design

Designed by 2 exercise physiologists working in consultation with both a medical doctor and a doctor of physical therapy, the SF program is a once weekly (60 minutes), 12-week iterative program with 3 core components: postural alignment and control, balance and mobility, and muscular strength and power. All instructors leading the training had, at minimum, a bachelor's degree in an associated field (kinesiology, exercise physiology, etc) and licensing as a personal trainer from an accredited national institution (American College of Sports Medicine, American Council on Exercise, and National Academy of Sports Medicine). In addition to the weekly group class, participants received both printed and recorded instruction regarding how to safely complete the exercises without supervision and were "assigned" homework materials and encouraged to practice 2 or more additional times per week preferably with a family member or friend present for safety.

All of the exercises introduced throughout the course were designed to be appropriate for an older adult population and were standardized so that participants received the same basic instruction, but the level of difficulty was scaled (and coached) based on individual capability, experience, and musculoskeletal limitations. Each week, new foundational exercises identified as being important to maintaining strength, postural control, balance, and mobility, and also relevant to specific daily activities (eg, picking up an object from the floor to place it on a countertop) were added to the class. In addition, over time, most exercises initially taught as isolated movements were expanded to more complicated, multijoint and multiplanar compound movements, once again with the intent to mimic daily movement.

Home Setup and Safety Concerns

One to two weeks before the first exercise class, participants were emailed instructions for setting up their exercise space at their residence. This included having, at minimum, a 6×6 ft uncluttered exercise space on either a nonslippery floor or an area with wall-to-wall carpet (no loose rugs) and adequate open space surrounding the designated exercise space. In addition, if possible, they were encouraged to have a small amount of wall space immediately behind their exercise area to allow for intermittent wall exercises. Participants were also provided with a set of resistance bands with the level of difficulty determined based on their self-described strength and were instructed to ensure that they had a chair without wheels (and preferably without arms) available for chair-based exercises and to assist with balance during standing exercise.

Intervention Delivery

One of the novel features of this program is the delivery of semi-individualized instruction in real time within a small group setting. To this end, classes were designed to have 10-15 participants. A single lead instructor provided verbal instruction while demonstrating each exercise. Simultaneously, at least 1, and sometimes 2, additional instructors provided individualized instruction to participants who were performing an exercise incorrectly or those who were ready to move on to a more difficult progression, with a particular emphasis on exercise form and safety. This allowed all participants to develop competency with key exercises while allowing those with experience and confidence to progress to more advanced movements in a timely manner.

In-person classes were offered once per week and lasted slightly longer than 1 hour. Classes began with approximately 5 minutes of aerobic warm-up during, which participants were encouraged to move somewhat vigorously in order to raise their heart rate and elicit blood flow to the working muscles. Following the warm-up, each class had different foci as shown in Table 1. Regardless of the focus of the week, 5-10 minutes were spent teaching the week's foundational exercises with particular emphasis on explaining proper form. In the early weeks of the intervention, participants were instructed to complete the exercises slowly, paying particular attention to ensure that they were feeling the target muscles activate or engage in the appropriate anatomical area. Individualized feedback from an assistant instructor correcting errors in technique was emphasized during this time, making sure that each participant received feedback from an instructor at least once during the class. As the weeks progressed, the lead instructor cued participants to increase the resistance or increase the speed, or increase both the speed and resistance concurrently during strength training exercises, as tolerated, and also increase balance challenges if they felt safe doing so.

Table 1. Weekly foci and foundational exercises.

Week	Foundational exercise 1	Foundational exercise 2	Foundational exercise 3	Foundational exercise 4	Focus of the week
1	Neutral spine or marionette pose	Pelvic tucks or tilts	Hip hikes	Hip hinge	Posture
2	Quick feet drills	Review hip hinge	"Traditional abs"	Self-test: static balance	Balance
3	Front and lateral arm raises (with band)	Hip hinge (review) with squat or chair sit or stand	Reverse lunge	Heel toe raises	Strength
4	Neutral spine and pelvic tuck or tilt—standing	Static balance	Reverse lunge with progression	Heel toe raises with tennis ball	Combine 3 pillars
5	Sit and stand transitions	Around the clock steps	Hip hinge with choice of W/T/Y/I arm extensions	Modified or regular jumping jacks	Floor to stand transition—floor exercises
6	Hip hinge (review) with squat or chair sit or stand	Lunge with chair progression	Single leg heel raises	Hing hinge+picking up objects	Compound strength movements
7	Drinking bird	Squat to lateral leg raise	Single leg heel raises	Toe raise walk around chair	Increase balance challenge
8	Warrior 2 with chair sit	Wall sit with wood chop	Introduce pivot	Quick feet multidirectional	Odd impact or multidirectional movements
9	Weight transfer with split stance	Squat into a high knee and arm reach	Pivot	Head rotations in a tandem stance	Combine balance with compound movements
10	Single leg stance with band pull downs and serial 7's	Lunge with chair support and head rotation	Standing superman with cognitive challenge	Goal post with arm slides	Introduce cognitive challenge
11	Reaching squats	Lateral jacks	Vertical push-ups	Knee drivers	Speed or power movements
12	N/A[a]	N/A	N/A	N/A	Collaborative workout

[a]N/A: not applicable.

For the remainder of the class, a variety of exercises focused on strength, balance, and posture (alone and in combination) in line with the focus of the week were completed in sets of 3 to 5 with pauses between sets to cue the next set of exercises. During the final 5 minutes, participants were guided through a brief cool down that incorporated stretching of the muscles used (most) during the exercise session.

Participants were also provided a secure link to a public-facing web-based video library that hosted a recording of the exercise session and a written description of the foundational exercises emphasized each week. Participants were further encouraged to complete 2 additional exercise sessions weekly. They also were provided a "mid-week challenge" 3 days after the weekly class session. These challenges included video presentations on the importance of posture in preventing falls, selected yoga-based movements for balance, and other short (5-10 minutes) presentations designed to keep participants engaged with the larger fall prevention focus of SF. Finally, participants were reminded of the importance of cardiovascular exercise and encouraged to walk or do other aerobic activities regularly.

Laboratory Measures

Overview

All measures were completed at baseline, prior to the first exercise class. Follow-up visits were completed anytime from the day after the 11th class through 2 weeks following the completion of the last (12th) exercise session. Participants completed their physical measures in the following order:

Balance and Physical Function

In-laboratory testing of balance and physical function included the Short Physical Performance Battery (SPPB) [28] combined with computerized dynamic posturography to quantify postural sway and the Timed Up and Go (TUG) [29].

Participants completed the standard SPPB, which includes (1) a standing balance challenge, in which the participant is asked to stand as still as possible with an increasingly narrow base of support; (2) regular walking speed at a "regular" pace on a 4-m course; and (3) leg strength gathered from the time taken to complete 5 chair stands. Continuous scores were normalized with a maximal score of 12 (4 points per measurement category) [28]. In an effort to address possible ceiling effects associated with the balance component of the SPPB, the BTrackS Balance Plate (version 7.5; Balance Tracking Systems) was used to capture overall postural sway, measured in centimeters.

Participants completed the TUG at both a normal walking speed and as fast as possible. Participants began in a seated position and were instructed to rise without using their arms to push off, walk 3 m, negotiate around an obstacle (rubber cone), return to their chair, and sit back down. Participants were allowed 1 practice trial and then completed each test twice with the best time (ie, lowest) score used for statistical analysis.

Postural Assessments

Posture was measured using a variety of methods designed to identify areas of postural deficiency. Specifically, for general posture, standing height was measured in two ways using a stadiometer (SECA 213) while participants were instructed to (1) "stand as you normally do" and (2) "stand as tall as possible." Both measurements were taken at the top of the breath cycle. To identify cervical and upper thoracic postural decline, the occiput to wall distance (OWD) [30] was measured in the same 2 manners (ie, regular and tall stance). More specifically, OWD was measured by having participants stand against a wall with their heels and buttocks touching the wall or as close as they could get comfortably. They were then instructed to look straight ahead (neutral head position) and hold still while the distance from the occiput to the wall was measured in centimeters. Finally, the Debrunner kyphometer and flexiruler were used to measure thoracic and lumbar curvature using previously published methodology [31,32]. Briefly, the Debrunner kyphometer provided an angle of curvature of the thoracic spine when placed in the joint space between T2 and T3 on one end and T12 and L1 on the other while participants stood in a normal or relaxed manner. The flexiruler is moldable and is placed with one end at the base of C7 and the other in the joint space between L5 and S1. The molded ruler is then traced onto a piece of paper, from which the kyphotic index was calculated by 2 independent raters as a function of the thoracic length and thoracic width using standardized procedures previously described (width/length×100) [31]. The average of the 2 raters was used for analyses.

Functional Muscular Strength

All participants completed a 30-second Chair Stand (30CS) and grip strength test. A subset (initial 3 cohorts of recruited participants) also completed isometric strength testing of hamstrings or quadriceps and trunk or lumbar muscle groups (procedure described in Isometric Muscular Strength section).

The 30CS used a chair with a seat height of 17 inches. Participants were instructed to keep their feet flat on the floor with their arms folded across their chest and touching their chest throughout the test. To be counted, the participant had to rise to a fully upright position and then return to a seated position while maintaining a fairly vertical body position (avoiding excessive forward lean). If participants did not maintain proper form, they were coached, but time was not stopped.

Hand Grip Strength

Hand grip strength was measured using an adjustable grip strength dynamometer (Jamar Plus Digital Hand Dynamometer). During the baseline visit, the grip or handlebar of the dynamometer was adjusted so the second joint of the fingers fits around the handle with handle size (1-5) recorded and used during subsequent visits. Participants were familiarized with the measurement by performing one submaximal effort on each hand. After becoming comfortable with the procedure, participants were instructed to hold the dynamometer with their arms at their side. They were then coached to take a deep breath in and squeeze as hard as possible as they exhaled. Measurement staff provided encouragement throughout each attempt. The measurement was repeated twice on each hand, alternating between the dominant and nondominant hand, with the highest score for each hand recorded in kilograms.

Isometric Muscular Strength

Isometric strength of the hamstrings, quadriceps, and spinal extensor muscles was measured using the Biodex System 4 PRO dynamometer (version 4.60; Biodex Medical Systems). Specifically, isometric strength of the hamstring and quadriceps muscle groups was measured with the leg held in at 45, 75, and 90 degrees of knee flexion. Participants performed 3 repetitions of 5-second maximal isometric contraction, extension followed by flexion, with 5 seconds of rest between repetitions at each angle. A 2-minute rest period was given between sets or leg positions. To decrease participant burden, only 1 leg was tested with participants indicating if either of their legs or knees had any previous injuries, or any current pain, after which the "healthiest" underwent testing. The average maximal contraction at each angle was recorded, and scores were combined into a flexion and extension composite score.

The Biodex Dual Position Back Ex/Flex Attachment, seated-compressed variation (isolated lumbar position), was used to measure the isometric strength of the trunk at 0 degrees of spinal flexion-extension (seated up-right). One set of 3 repetitions of 5-second maximal isometric contractions for both trunk flexion and extension was completed by participants. A 10-second rest was given between repetitions. To minimize the risk of injury, participants were instructed to slowly and gradually increase their muscle engagement to a volitional maximum and not attempt any sudden or explosive movement against the resistance.

Aerobic Fitness

Participants were asked to walk continuously for 2.5 minutes at their normal walking speed on a 50-m corridor [33]. During the walk, participants wore a chest strap–based heart rate monitor (Polar H10). Total distance, average heart rate, and peak heart rate were recorded.

Statistical Analyses

All statistical analyses were conducted using SPSS (version 27; IBM Corp). As this was largely designed as a feasibility study to determine the acceptability of this novel intervention delivery method and the degree to which the intervention could improve metrics of strength, balance, and posture, power calculations were not conducted. Instead, the sample size was primarily determined by safety concerns involving class size, which we settled on 10-15 per class after conducting 3 brief, 4-week pilot sessions beginning with ~6 participants, increasing to 8-12 to keep class size manageable. The sample size was also restricted by fiscal constraints.

Descriptive statistics (percentages, means, and SDs) were used to characterize demographic variables and identify potential outliers. Change scores were derived by subtracting baseline values from follow-up values on an individual level.

Independent 2-tailed *t* tests were conducted to assess differences across groups at baseline. Paired sample *t* tests were conducted to evaluate the effects of the intervention on the measures of

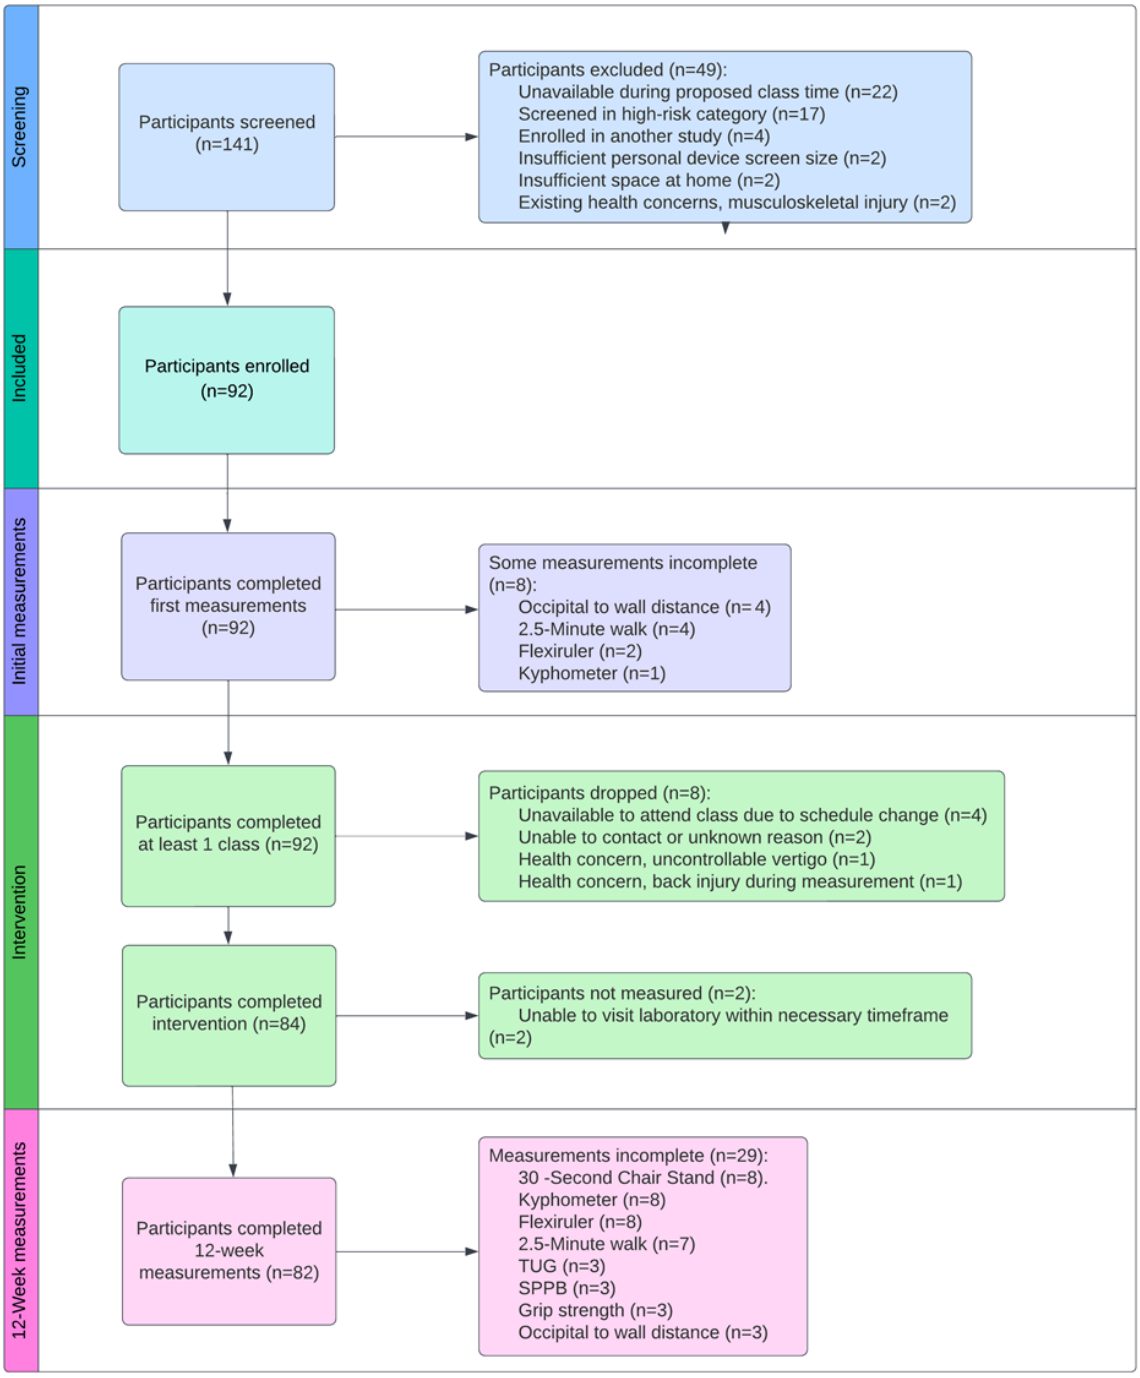
interest, with analyses conducted both for the total population and also with participants divided into fall-risk groups, which were assessed independently of each other. Associations between changes in measures of strength, balance, and posture and number of classes attended were examined using Pearson correlation without controlling for any covariates. When associations were observed, univariate linear modeling was conducted, with sex, chronological age, and baseline score included as covariates. These were included based on the known systematic declines in performance in older individuals, the possibility of systematic differences between male and female individuals, and the differences in potential change associated with baseline performance.

Results

Overview

The number of participants screened, enrolled, and followed through the final measurement is shown in Figure 1.

Figure 1. Participant recruitment flow. The sum of the breakdown of excluded participants at the initial and 12-week measurements exceeds the total number of excluded participants, as some individuals missed more than one assessment. SPPB: Short Physical Performance Battery; TUG: Timed Up and Go.



Population Descriptive Data

A total of 92 participants were enrolled across 8 cohorts with 55 low-risk and 37 moderate-risk individuals assigned to their own risk-group classes (n=4 classes per risk group). Key demographics and population descriptive data are shown in Table 2. The majority of the population was female (n=77, 84%) and White (n=74, 80%). Participants were largely well educated, with all participants having some college degree, and 91% (n=84) having a bachelor's degree or beyond. Additionally, although very few were currently employed (n=15, 16%), the majority (n=55, 60%) of participants were at a high socioeconomic status (>US $100,000 income), with 19 (21%) individuals earning more than US $200,000 per year.

As expected, based upon the group stratification, there was a difference in STEADI fall risk score between groups. Additionally, those at moderate risk (STEADI >3 but <8) were slightly heavier (low risk: mean 64.2, SD 11.3 kg and medium risk: mean 71.6, SD 17.7 kg; *P*=.008) and with a higher BMI (low risk: mean 23.8, SD 3.9 kg/m^2 and medium risk: mean 26.5, SD 5.2 kg/m^2; *P*=.003).

Performance metrics at baseline and following the 12-week intervention are shown in Table 3. There was a difference at baseline between the low- and moderate-risk groups on the 30CS (*P*<.001), TUG (*P*=.002), walking distance at normal speed over 2.5 minutes (*P*<.001), SPPB (*P*<.001), and the OWD measures of posture (normal stance: *P*=.007 and tall stance: *P*=.005). In all of these cases, the moderate-risk group had worse performance compared to the low-risk group. However, strength and balance and some measures of posture (flexiruler and Debrunner kyphometer) were not different by risk category.

[c]SPPB: Short Physical Performance Battery.

Balance and Physical Function

On average, at baseline, participants were able to complete slightly more than the minimum number of chair stands (n<12) to be considered free from disability [34]. However, 38 (41%) individuals were below that level. In contrast, on average, participants were well above the minimum threshold to identify disability for the TUG and SPPB (>13.5 seconds and <9, combined score respectively) [35,36], with 0 for TUG and 14 (16%) for SPPB below the threshold. In terms of the effects of the intervention, there were no significant changes in postural sway during static balance stances associated with the SPPB.

However, overall participants significantly improved on the 30CS and TUG (mean change of 1.4 repetitions: *P*=.006 and 0.2 seconds: *P*=.004, respectively). While not always statistically significant, the moderate-risk group improved to a greater degree on both of these assessments than the low-risk group (although both groups improved). Additionally, SPPB performance improved significantly in the moderate-risk category (*P*=.02).

Posture

Although there were no inclusion or exclusion criteria related to posture, there were a meaningful number that displayed suboptimal posture. Indeed, depending upon the measurement tool and associated categorical cut-points used, between 7% and 26% of the total sample were hyperkyphotic (flexiruler: n=7, 8%; kyphometer: n=12, 13%; OWD [normal stance]: n=24, 26%). The majority of postural measures showed statistically significant improvement following the intervention. Indeed, measures of "relaxed" posture showed improvements between 6% (n=5; Debrunner kyphometer) and 27% (n=22; OWD). When an "as tall as possible" posture was adopted for the OWD, the improvements were greater at ~36% change from baseline. These changes are even more impressive when individuals who had no opportunity for improvement are removed (ie, individuals who scored 0 on OWD at baseline). Specifically, when the 18 individuals standing normally and 47 as tall as possible who scored 0 are removed, overall change scores with normal stance were 1.7 cm, and with tall stance were 2.2 cm.

Muscular Strength

We did not observe significant differences in grip strength (*P*=.54) However, as mentioned earlier, 30CS is a marker both of functional movement but also muscular strength (and endurance) and had significant changes across the population (*P*=.006) Finally, in the subgroup that completed isometric testing, there was a significant improvement in knee extension (*P*=.02) and both trunk extension and flexion (*P*=.03 and <.001, respectively).

Aerobic Fitness

There were no significant changes in measures of aerobic fitness measured by the 2.5-minute walk at normal speed.

Associations Between Class Attendance and Functional Measures

When exploring associations between change scores and rates of attendance, the TUG (*r*=–0.255; *P*=.03) and 30CS (*r*=0.27; *P*=.02) were significantly correlated; however, there were no significant associations between class attendance and changes in physical function on the majority of other variables (*P*>.05). Regression analysis controlling for sex, age, baseline measurement, and number of classes attended indicated that attendance was not a significant predictor of change in TUG, although including it did slightly improve the model's predictive value (from *R*=0.45 to 0.49). However, attendance was a significant predictor of improvement in the 30CS (unstandardized β=.502; *P*=.02). This indicates that for each class attended, there was a 0.5 increase in the change score in terms of number of repetitions. Model summary and individual contributions of variables and covariates are shown in Tables 4 and 5.

Adverse Events

Based upon weekly tracking, there were several minor adverse events throughout the intervention period. However, none were related to the exercise intervention, and only 1 minor event was possibly related to the measurements. Additionally, there were no falls associated with the intervention, either while supervised during class or performed on nonclass days.

Discussion

Principal Findings

In this 12-week, iterative, web-based program, we found that older adults experienced an improvement in several measures widely used to evaluate fall risk and mobility-related disability [7,28,34]. While the magnitude of most of the changes was small, they were primarily consistent in the expected direction, which is not surprising because the program was designed to be largely instructional rather than a progressive training program. Instructors emphasized proper form and execution while maintaining good posture. Increases in the intensity of resistance exercises and challenges to balance and mobility exercises were only introduced once instructors observed consistent execution of movements. Importantly, no injuries were sustained during the remote delivery of our program or during the recommended home exercise practice.

Most muscular strength and physical function measures showed favorable changes in both the low- and moderate-risk groups, although not all results reached statistical significance. Nevertheless, the observed changes have clinical relevance. For instance, the intervention induced meaningful improvements in measures commonly used in clinical settings, such as the 30CS and TUG tests. Notably, many improvements varied by risk level, with greater gains seen in those at higher fall risk, who arguably had more to gain from the intervention. Specifically, participants in the moderate-risk group completed an additional 2 chair rises (a 21% improvement) by the end of the 12 weeks. Given that both leg strength and muscular endurance are essential for scoring well on the 30CS, the observed improvement in chair stands may be attributed to the focused practice of squat and related exercises in class as well as encouragement for similar home practice. While upper body or arm strength is important to overall good health and function, they do not substantially contribute to fall prevention and were therefore not heavily emphasized in our home practice recommendations. Similarly, the lack of significant changes in aerobic capacity was expected based on the program's goals and the unique challenges of aerobic activities conducted via a Zoom format (Zoom Video Communications).

Additionally, these findings also contextualize participant gains by providing deeper phenotypical measurements related to posture, more sophisticated measures of strength, and balance. For example, there were positive changes recorded in measures of thoracic kyphosis and OWD across both risk groups. This is important because posture is often overlooked in many group exercise programs for both younger and older adults. In this study population, posture measured as the kyphotic angle using a Debrunner kyphometer decreased 2-3 degrees (P=.02 and .07 for low- and moderate-risk groups, respectively), while the OWD decreased between 1 and 1.4 cm (all P<.05) among participants in both groups over the once-weekly, 12-week exercise program. Considering that thoracic kyphosis typically worsens steadily over time beginning as early as age 40 years [37-39], observing a reversal of this condition within just 12 weeks of targeted exercise is highly encouraging. This is particularly meaningful, given the observed links between hyperkyphosis and both fall risk [26,40] and physical function [41,42].

Although there were no significant differences observed in grip strength, it is likely that the prescribed exercises contributed to an enhancement of the participant's back strength [43] and chest flexibility, which helped alleviate the tightness in chronically shortened pectoral muscles [26]. These improvements not only reflected positively in participants' attempts at maintaining "good" posture (as measured by OWD while standing tall) but also in their "normal" posture as assessed by various tools. These changes in both "good" and "normal" posture likely stemmed from the early introduction of postural control as a foundational element of the program as well as ongoing reminders throughout the course for participants to practice maintaining good posture during daily activities. It is worth noting that postural control is seldom included in group exercise training programs, making this approach particularly novel and engaging, thereby providing participants with more opportunities to learn and improve compared to more traditional exercise modalities such as aerobic activities or strength training.

While there have been some similar findings regarding the possibility of providing digital exercise instruction to older adults [17-19], this is, to our knowledge, the first study to robustly measure a large population of older adults across multiple metrics of physical health and function. Our findings clearly demonstrate the potential to deliver an effective fall prevention program through a technological interface. The program was well-received, as indicated by an attendance rate exceeding 80% (mean attendance 9.7 of 12), and no adverse events were reported in association with the exercise regimen. Additionally, the observed improvements in leg strength, postural control, and overall mobility, both independently and synergistically, show promise for reducing falls among older adults, including those at substantial risk.

Limitations

Despite several strengths of this study, certain limitations must be acknowledged. Chief among them is the absence of a control group, which limits our ability to ascertain whether observed changes were influenced by external factors. A control group would also help clarify the significance of nonsignificant changes observed in some metrics, particularly in light of the expected performance declines over time. Additionally, although there were improvements in most metrics of strength and posture, balance as measured in this context was not improved. This may be a function of the method of measuring static balance (ie, postural sway during the SPPB). However, it may be that the program's focus on balance was not sufficient to induce changes over 12 weeks. Furthermore, unlike many exercise interventions for adults of all ages, we did not emphasize cardiovascular health other than recommending daily general PA. While recognizing the importance of aerobic activity for overall health and longevity, instructional focus on this area was minimal; encouragement for at-home exercise emphasized practicing postural, strength, and balance-based exercises. Finally, the relatively affluent nature of the population limits the generalizability of both the results and the ability to disseminate this program to a wider population.

With the success of this program and the limitations noted earlier in mind, future research should explore the possibility of deploying this intervention in populations that are (1) of a lower overall socioeconomic status and (2) more remote from the location of intervention deployment. In addition, developing these materials into other languages in a culturally appropriate manner offers substantial potential to expand the reach to other populations who would benefit from the opportunity to receive at-home fall-risk training.

Conclusions

The 12-week SF program improved physical function and posture in ways consistent with reduced fall risk. The real-time instruction also helps ensure program safety and adherence. As such, this program shows promise in digitally delivering needed public health interventions targeting fall risk among older adults.

Acknowledgments

Study data were collected and managed using REDCap (Research Electronic Data Capture) electronic data capture tools hosted at the University of California, San Diego (UCSD). The REDCap software system provided by the UCSD Clinical and Translational Research Center is supported by (award UL1TR001442) the National Center for Research Resources. The authors would like to thank Ms Ashley Gauthie and Ms Sharmaine Olivarez for their work in managing the technical elements of Zoom-based intervention deployment. The authors would also like to thank their funder, the UCSD Clinical and Translation Research Center.

Abstract

Background: Falls are a prevalent and serious health condition among older people in residential aged care facilities, causing significant health and economic burdens. However, the likelihood of future falls can be predicted, and thus, falls can be prevented if appropriate prevention programs are implemented. Current fall prevention programs in residential aged care facilities rely on risk screening tools with suboptimal predictive performance, leading to significant concerns regarding resident safety.

Objective: This study aimed to develop a predictive, dynamic dashboard to identify residents at risk of falls with associated decision support. This paper provides an overview of the technical process, including the challenges faced and the strategies used to overcome them during the development of the dashboard.

Methods: A predictive dashboard was co-designed with a major residential aged care partner in New South Wales, Australia. Data from resident profiles, daily medications, fall incidents, and fall risk assessments were used. A dynamic fall risk prediction model and personalized rule-based fall prevention recommendations were embedded in the dashboard. The data ingestion process into the dashboard was designed to mitigate the impact of underlying data system changes. This approach aims to ensure resilience against alterations in the data systems.

Results: The dashboard was developed using Microsoft Power BI and advanced R programming by linking data silos. It includes dashboard views for those managing facilities and for those caring for residents. Data drill-through functionality was used to navigate through different dashboard views. Resident-level change in daily risk of falling and risk factors and timely evidence-based recommendations were output to prevent falls and enhance prescriptive decision support.

Conclusions: This study emphasizes the significance of a sustainable dashboard architecture and how to overcome the challenges faced when developing a dashboard amid underlying data system changes. The development process used an iterative dashboard co-design process, ensuring the successful implementation of knowledge into practice. Future research will focus on the implementation and evaluation of the dashboard's impact on health processes and economic outcomes.

Introduction

Falls are the second leading cause of unintentional injury deaths worldwide, with those older than 60 years having the highest risk of death or serious injury [1]. People living in residential aged care facilities (RACFs; ie, nursing homes and care homes) are three times more likely to fall than their community-dwelling peers and are ten times more likely to sustain fall-related injuries [2]. Studies have found that falls are often predictable and preventable and that the health and economic burden of falls could be minimized if effective prevention strategies are implemented [3-5].

Falls prevention is an issue of major importance in RACFs. Various fall risk assessment tools (FRATs) are used by RACF staff internally to identify residents at greatest risk of falls [6]. However, when assessed, the predictive performance of these tools has generally shown to be poor [6,7]. Moreover, FRATs are most often completed when residents are admitted to a facility or after a fall incident, and thus, only represent data collected at a single point in time, resulting in a static prediction that does not reflect changing falls risk factors (eg, if a resident's medication use changes) [6].

As a growing number of RACFs implement electronic health record (EHR) systems, new opportunities have emerged to develop a personalized, dynamic approach to predicting residents' fall risk by taking advantage of multiple potential contributory factors [8]. Some studies have integrated routinely collected EHR data including vital signs into the development of fall prediction tools through the application of machine learning models [9]. Despite these tools exhibiting superior performance in contrast to conventional FRATs, the risk predictions generated are often difficult to interpret and apply in practice. Thus, relying solely on these models will not enhance decision-making to provide a personalized care strategy for fall prevention and management. Health dashboards that can integrate these predictive models in combination with visualization features may be a more effective intervention for supporting staff in RACFs.

A dashboard can be defined as an at-a-glance real-time or near real-time processing interface, showing a graphical presentation of the current or recent status, along with historical trends or organizational key performance indicators to support decision-making [10]. There have been some attempts to develop a dashboard for fall prevention purposes globally. The falls dashboard, developed by the Network of Patient Safety Databases and managed by the US Department of Health and Human Services, collects nonidentifiable patient-related fall incident data from health care service providers. These data are then aggregated to a national level, analyzed, and visualized using the Network of Patient Safety Database dashboards and chartbooks to identify and track patient safety risks nationally [11]. Similarly, the New Zealand Health Quality and Safety Commission has established a falls and fracture outcomes dashboard to help the health sector evaluate the benefits of the services provided to older people [12]. Such aggregated dashboards are helpful for monitoring, although they offer limited assistance in predicting and preventing falls in routine care settings. To the best of our knowledge, no previous study has reported the development of a dashboard designed to predict fall risks for individual residents and aid decision-making in preventing and managing falls. As part of a comprehensive research program aimed at enhancing fall prevention and the well-being of older adults in RACFs [8], this paper details the design and development process of a predictive analytics dashboard with prescriptive decision support for fall risk prediction, prevention, and management. We discuss the challenges encountered and the strategies used to overcome them during its development.

Methods

Participants

This project was conducted in collaboration with a large, aged care provider that operates 24 RACFs in Sydney, Australia. The development process of the dashboard spanned from January 1, 2022, to December 31, 2023. For the dashboard views and study sample, this study used data from both respite and permanent residents who were present in a RACF between January 1, 2021, and December 31, 2021. The dashboard was designed using participant data that was extracted onto Excel sheets from the provider. After the development, the dashboard was connected to the provider's live data sources through a data lake.

Ethical Considerations

All methods and analyses in this study were conducted in accordance with the principles of the Declaration of Helsinki. The study received ethics approval from the Macquarie University Human Research Ethics Committee (52019614412614). As a retrospective cohort study using deidentified, routinely collected aged care data, a waiver of informed consent was granted by the committee, in line with the Australian National Statement on Ethical Conduct in Human Research (Sect. 3.3.14(a)), which allows for the use of previously collected deidentified data.

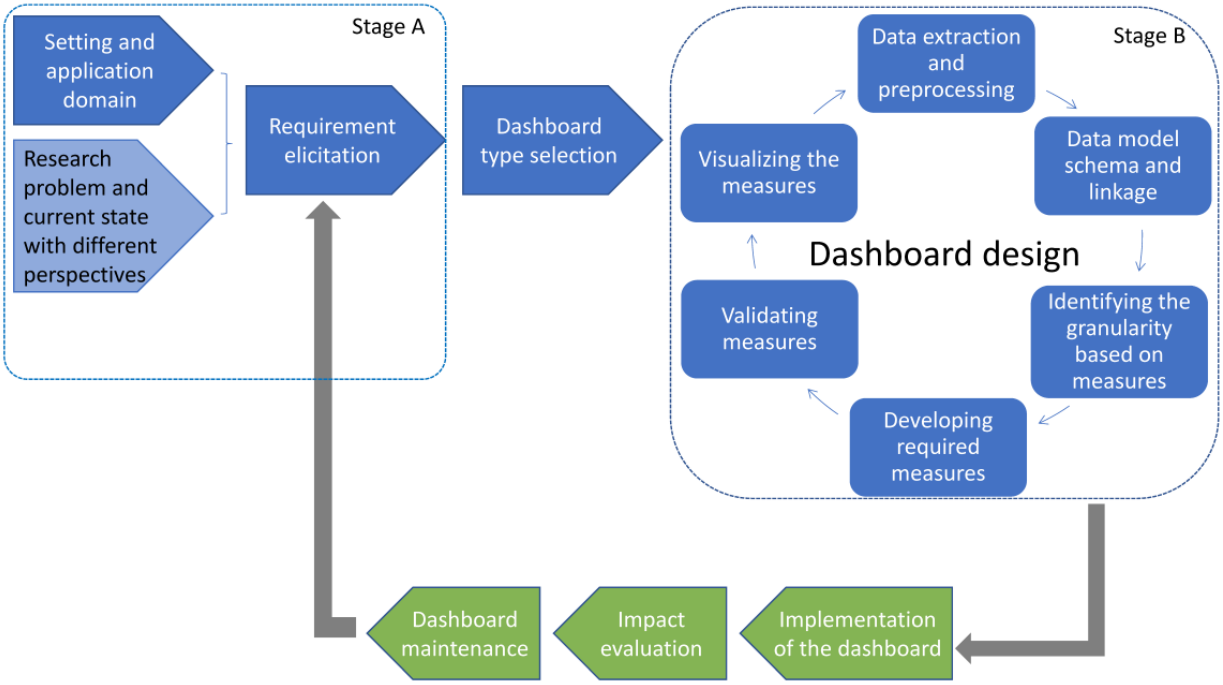
Dashboard Development Process

Overview

We followed an iterative process to co-design the dashboard, with intended dashboard end users (ie, RACF staff, general practitioners, and consumers at RACFs), along with domain experts in the field of falls prevention and management. Figure 1 highlights the dashboard development process followed during the study. The stakeholders were involved continuously in Stage A and Stage B through regular discussions, interviews, and

workshops, which will be described in detail elsewhere. The steps colored in blue are described in this paper and the final steps relating to implementation and evaluation colored in green are in progress and will be reported in subsequent papers.

Figure 1. The dashboard development process.



Setting and Application Domain

Domain knowledge can be defined as the knowledge about the environment in which the proposed system will operate [13]. Domain knowledge was obtained from the aged care provider through discussions and analysis of data related to falls incidents and the Peninsula Health Falls Risk Assessment Tool (PH-FRAT) risk assessments (ie, to determine the current falls rate across facilities, the characteristics of falls incidents and contributing factors listed in falls incidents). PH-FRAT was developed in 1999 by Peninsula Health in Victoria, Australia, and is a validated and user-friendly tool for screening and assessing fall risk, as well as managing strategies to reduce this risk [14]. Information about predictors of falls and strategies used to prevent falls in the RACFs was obtained by systematically reviewing published literature on predictive models for fall prevention, and the effectiveness of fall prevention interventions [15,16]. The identified predictors of falls in older people have been incorporated into the development of the embedded predictive model, which is reported elsewhere [17].

Research Problem and Current State With Different Perspectives

Considering the suboptimal predictive performance of current tools [6], there is a need for a dashboard embedded with a dynamic predictive model and decision support (research problem). Moreover, falls prevention and management requires action at different levels of an organization's hierarchy from management to clinical staff. Therefore, it was important to gather different perspectives. For this purpose, a series of discussions were held between researchers and RACF stakeholders across a 2-stage process (Figure 1). In Stage A discussions, different perspectives on falls prevention and management in RACFs were gathered while identifying the dashboard stakeholders and their information requirements. In Stage B, dashboard stakeholders engaged in rounds of iterative feedback workshops to support the dashboard designing process. A qualitative analysis of these interviews will be reported elsewhere.

Requirement Elicitation

The requirement elicitation stage was based on three fundamental tasks: (1) identifying the individual stakeholders; (2) eliciting stakeholder requirements depending on the role of the stakeholder; and (3) integrating, refining, and organizing the requirements identified [18].

In Stage A, baseline interviews were conducted to understand the current utilization of health care data and information by potential dashboard end users. The aim was to identify the information requirements essential for enhancing decision-making in a clinical dashboard. In this process, the individual stakeholders and information providers of the dashboard were identified along with their high-level user expectations [10]. This also facilitated a precise understanding of the individuals with different perspectives of falls prevention and management, who would be accessing each dashboard view. The information collected from these interviews was used to define measures that should be generated in the dashboard backend.

From these identified measures, the designers then evaluated the variability of information and organized the information requirements based on the level of reporting in the dashboard

(ie, resident level, facility level, or organizational level). This further supported the dashboard design stage in arranging visual plots and tables within views.

Dashboard Type Selection

Power BI (PBI; Microsoft Corp) was selected on the grounds of digital data visualization, easy implementation at the user end, and stable R programming integration for advanced statistical analysis and plots. In this step, the initial prototype of the dashboard was created and shared with our partner organization and refined through collaborative efforts.

Dashboard Design

Overview

The aim of this step was to meet the user requirements for preventing and managing falls by effectively presenting resident data and fall risk information to support informed decision-making. As in Figure 1, this step included an iterative process that included data extraction, preprocessing, and linkage along with identification of the granularity of data, development, validation, and visualization of the measures on the front end.

Data Extraction and Preprocessing

Access to four datasets was obtained: the resident profile (includes residents' demographics and admission information); all medications administered to residents; the organization's PH-FRATs (this aged care providers used the PH-FRAT) to obtain information related to falls risk assessments; and incident dataset (includes information related to all fall incidents and pressure injuries; Table S1 in Multimedia Appendix 1).

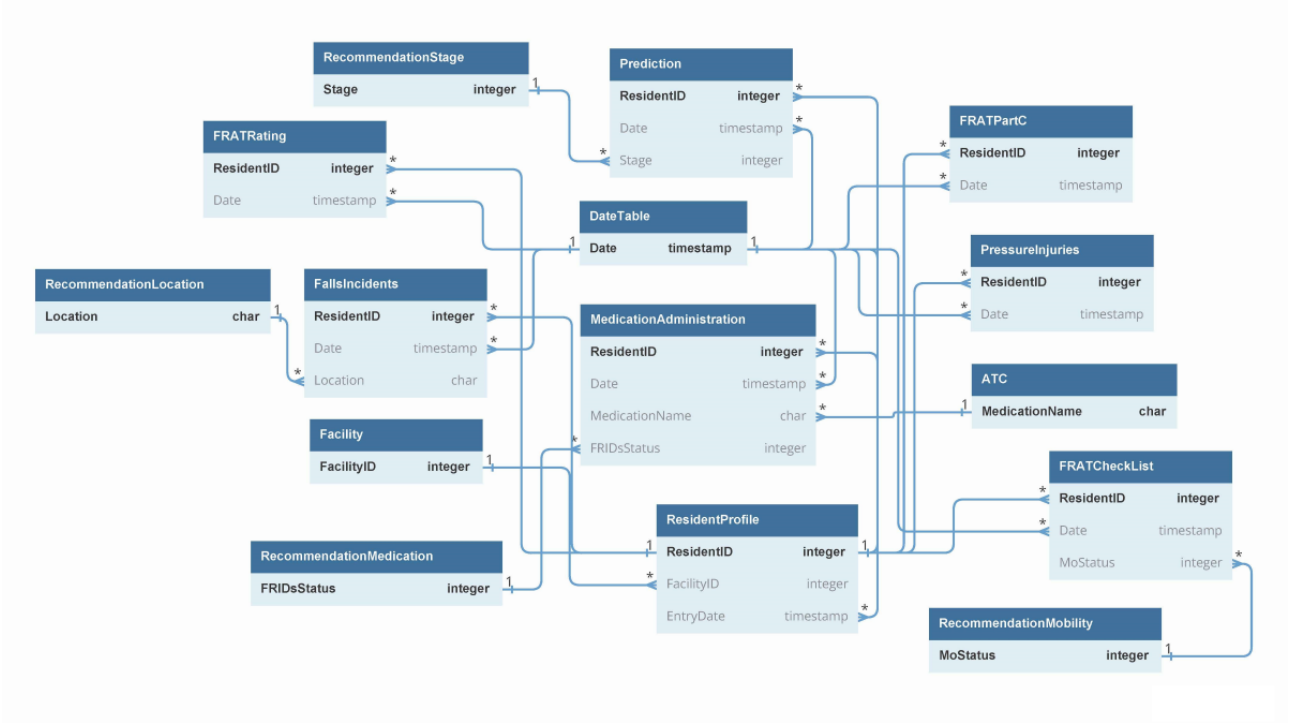
The profile dataset included a free text field that reported the comorbidities along with other special needs of the patient at admission (ie, health status). From this field, comorbidities present at admission were identified using the R-programmed version of the "aged care health status algorithm" [19] within PBI. The algorithm identifies the health conditions using free text fields from EHRs [20]. All medications in the dataset were coded using the Anatomical Therapeutic Chemical codes [21]. These datasets were then linked in the dashboard backend.

The extracted datasets for the study period underwent an external analysis for this study using R programming language (version 4.3.3; R Core Team) and were also subsequently used for its intended purpose within PBI. A descriptive analysis of the admission-related information from the resident profile dataset is reported appropriately (Table S2 in Multimedia Appendix 1). Resident characteristics from the resident profile dataset, FRAT dataset, and daily medication administration data are recorded in Table S3 in Multimedia Appendix 1.

Data Model Schema and Linkage

A star schema was adopted as much as possible where the fact table is centered and surrounded by the multiple dimension tables. The resident profile dataset was used as the main fact table that contains quantitative information (facts) about the residents [22]. Other datasets were used as dimension tables, which describe the events that residents experience during their stay [22]. The data tables were then linked as presented in the simplified form of the database schema as shown in Figure 2. The real schema on the backend of the dashboard is an extension of this and is more advanced.

Figure 2. Simplified view of the data model schema. ATC: Anatomical Therapeutic Chemical code; FRAT: falls risk assessment tool.



Identifying Granularity Based on Measures

To determine the granularity of the data tables, we considered the dashboard end users, information requirements (measures), and level of reporting that were preidentified. This step was done in parallel or a back-and-forth manner with the data model schema (ie, preceding step) and development of required measures (ie, proceeding step). A higher granularity was

preferred for most of the datasets to maintain sustainable analytical power to answer new user requirements within the designing stage [23]. Subsequently, the data tables were transformed to simply calculate the measures, or measure calculations were adjusted in a way to meet the form and granularity in the extracted tables. In certain instances, highly granular data tables were summarized to a lower-level granularity to support the prediction model and avoid intricate calculations during measure development.

Developing the Required Measures

In this step, measures were calculated on the transformed tables using Data Analysis Expression (DAX). Measures related to some figures such as funnel plots were created using embedded R programming in the PBI backend.

Validating the Measures

To ensure the accuracy and reliability of the information presented, the calculated measures were validated with provider-extracted datasets. The user input filters on each view were also tested during the validation process to identify whether there were any errors. If errors were identified in the data, remedial action was taken after a thorough examination of the underlying causes, in data extraction, data linkage, data preprocessing, or DAX formula.

Visualizing the Measures

The calculated measures were appropriately visualized using statistical plots, tables, and responsive figures on the dashboard, which comprises several dashboard views intended for various users at different levels in the hierarchy. The above-mentioned steps within the dashboard design stage were enclosed in a co-design process as explained below.

Dashboard Co-Design and Work Process Features (Stage B)

The core constructs of the integrated Promoting Action on Research Implementation in Health Services [24] framework were considered to facilitate innovation in the development of the dashboard: (1) innovation refers to the alignment of new insights including the predictive risk of falls captured by the dashboard with the current priorities and practices for falls prevention at RACFs, (2) recipients refer to the RACFs staff and other external stakeholders who will be affected by and influence the implementation of the dashboard, (3) context refers to the RACFs including the organization (inner layer) and wider health system (outer layer) around falls prevention and management, and (4) facilitation refers to the process that activates the implementation through assessing the characteristics of the three previously mentioned constructs.

The core constructs were integrated into the dashboard development process and the design was meticulously refined through a series of workshops (ie, facilitation) involving diverse teams of experts from various layers. These teams included general practitioners, geriatricians, allied health staff from RACFs (including nurses and clinical care managers), and human-computer interaction experts (ie, recipients). The collaborative workshops aimed to identify and implement enhancements to the dashboard, ensuring that it caters to the needs and preferences of all relevant stakeholders (ie, innovation). The design features (eg, color, graph types, positioning, filters, slices, and data views) and content for decision-making (ie, information included or missing on the dashboard and predictive model output) were considered. In these workshops, the development stage prototypes were presented to gather information on decision-making on client care and to identify the dashboard views that required improvements in managing falls. Current priorities and practices involved in managing falls at RACFs (ie, context) were also identified.

Descriptive and Diagnostic Analytics: Measures, Indicators, and Statistical Tests

All falls, injurious falls, and falls requiring hospitalization were identified as the main indicators in the dashboard. The total number of falls, the crude incident rate (ie, falls rate per 1000 resident days), the percentage of injurious falls, and the percentage of hospitalization were calculated for each outcome measure to enhance the decision support capability at an organizational level.

Funnel plots were used to visualize crude incident rates with 95% and 99% control limits, relative to the number of admissions. A time series plot was used to visualize the percentage of injurious falls and hospitalization due to falls.

Predictive Analytics With Resident Tailored Recommendations: Dynamic Falls Predictive and Monitoring Model

A dynamic predictive tool was developed to classify each resident's risk of falls using a technique called stratified landmarking and reported in detail elsewhere [17]. Initially, 116 variables were screened, and the most relevant variables on the fall outcome were selected using Collett's [25] variable selection approach. Two separate models based on dementia status were developed [17]. The final two models were based on patient demographics, dementia status, fall risk–increasing comorbidities such as cerebrovascular accident, visual impairment, osteoporosis or fracture, medication use, falls history, other risk factors such as psychological status, mobility status, behavior status, and activities of daily living [17].

The predictive model used in this study was developed and internally validated using retrospective data from the same provider [17]. The scores based on model coefficients and baseline hazards were then embedded into the dashboard backend and calculated the resident's probability of falling in a near real-time manner. The predictions generated by the model are updated every 24 hours given the modifiable risk factors such as medication use, previous fall incidents, and comorbidities.

As mentioned in the introduction, relying solely on a predictive model will not improve decision-making for developing a personalized care strategy for fall prevention and management. Additionally, the dashboard that visualizes risk factors at both the resident and facility levels should be used to enhance the interpretability of these predictions and other associated risk factors of falls. This dashboard visualizes the risk factors for falls, along with changes in risk and risk stages derived from

the predictive model. Furthermore, to offer a more prescriptive approach based on these predictions, evidence-based, resident-tailored recommendations have been developed as follows.

Resident-tailored recommendations are generated using a rule-based system in the dashboard's backend. The system identifies residents' mobility issues from PH-FRAT data and detects the use of fall risk–increasing drugs (FRIDs) from daily medication records. Fall incident data are used to determine the most frequent fall locations, while a predictive model assesses the current fall risk. Based on these factors, rule-based recommendations [26-28] are created and displayed in the resident fall view (Table S4 in Multimedia Appendix 1). Additionally, strategies identified through clinical judgment in the PH-FRATs are also displayed to enhance the personalization.

Results

Descriptive Profile of the Aged Care Provider, Facilities, and Residents

The aged care provider managed 24 RACFs. During the period of dashboard development, these RACFs housed 3686 resident admissions from 3057 unique residents. The median facility size was 124 (IQR 86-160) residents. Of the resident admissions, 71% (n=2622) were permanent. The median length of stay was 373 (IQR 41-1266) days (Tables S1 and S2 in Multimedia Appendix 1).

Dashboard Evolution Within the Design Stage

The Stage A interviews and Stage B workshops identified themes and findings related to content, design, functionality, and decision support. This led the dashboard to evolve through a series of iterations (Multimedia Appendix 2). Two dashboard views namely, organizational falls and facility falls were designed for organizational managers, while another two views were designed for care staff and focused on residents, resident falls, and resident-level medications in detail. The intervention recommendations gathered on fall prevention and management from published randomized controlled trials, government reports, systematic reviews, and meta-analyses [26-28] are included in the recommendation panel for education purposes.

Measures Developed in Dashboard Views

Textbox 1 presents the measures developed for each dashboard view. Given the interrelatedness of these views, certain measures used at the organizational level (such as total falls and falls rate [per 1000 resident days]) were also included at the facility level, while certain measures used at the resident level (ie, FRIDs use in last three days and polypharmacy indicator) were included in the medications in detail view.

Textbox 1. Measures available in the dashboard.

Organizational falls

- Total falls
- Total falls requiring hospitalization
- Total injurious falls
- Falls rate (per 1000 resident days)
- Falls requiring hospitalization rate (per 1000 resident days)
- Injurious falls rate (per 1000 resident days)
- Number of admissions per selected period
- Resident days per selected period

Resident falls

- Current falls risk
- Current risk category
- Daily percentage change in risk
- Falls in last 6 months
- Fall risk–increasing drugs (FRIDs) use in the last three days
- Change in FRIDs use in last three days
- Polypharmacy indicator
- Antipsychotic indicator
- Recent falls risk assessment tool (FRAT) assessment date
- Recent cognitive status identified by Peninsula Health-FRAT
- Recent psychological status

Facility falls

- Total number of residents
- Residents having stage 1 pressure injury
- Residents having stage 2 pressure injury
- Residents having stage 3 pressure injury
- Residents having stage 4 pressure injury
- Residents having unstageable pressure injuries
- Residents having deep tissue pressure injuries
- Residents with a pressure injury

Medications in detail

- Polypharmacy indicator – without pro re nata and short course
- Daily FRIDs indicator
- Daily change in FRIDs
- Daily change in opioid use
- Daily change in anxiolytics
- Daily change in hypnotic and sedatives
- Daily change in beta blocking agents
- Daily change in vasodilators
- Daily change in antidepressants

Dashboard Architecture

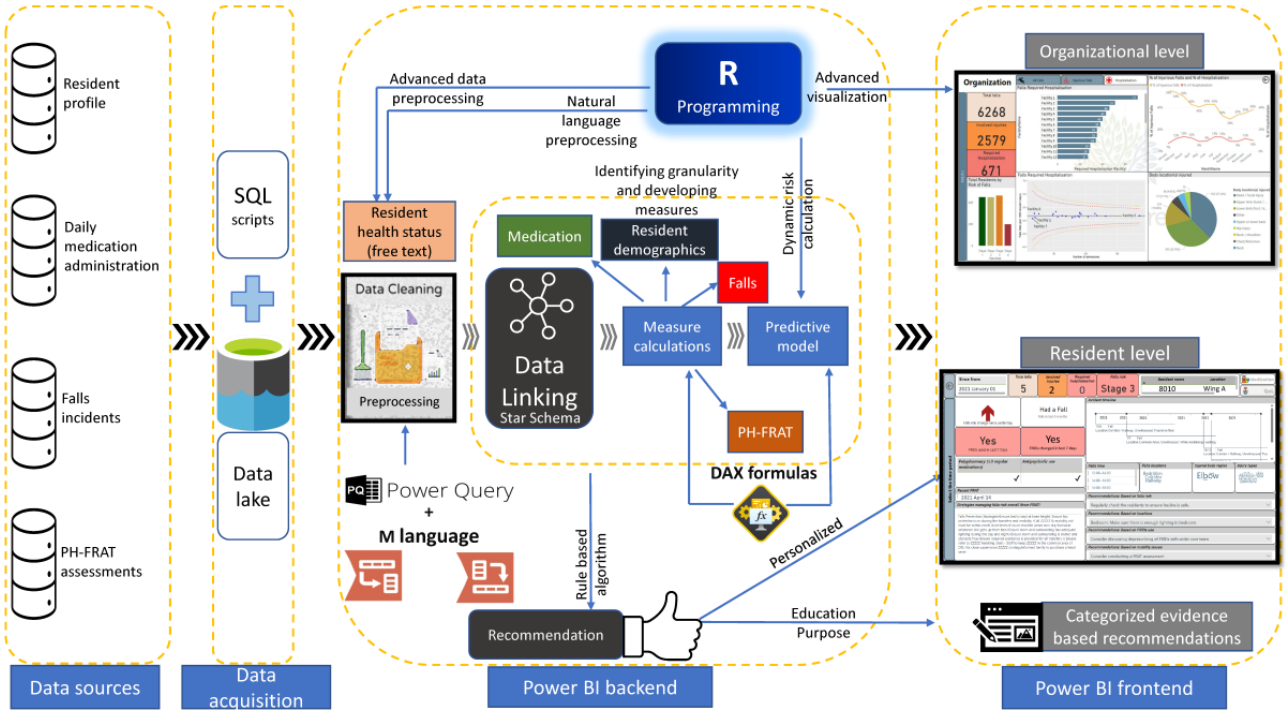
Data flows through 4 layers, to formulate the necessary information (Figure 3).

The first layer includes the data sources where the aged care provider collects and stores data. The next layer is the data acquisition layer. It includes data extraction scripts such as SQL scripts, which collect data from the previous layer. As the dashboard was developed without a direct connection to the above data silos (sources), the data extractions at the beginning were done using SQL scripts for each data silo, including the original variable names and formats. This layer is also helpful in maintaining the reliability of the dashboard when underlying IT systems change by storing the original form of data that is compatible with the dashboard backend, which is the next layer. At implementation, this layer will be replaced with a data lake that feeds provider-level data to the dashboard backend.

Then the data extracted from the data lake are preprocessed and linked at the backend of the dashboard using the data model schema discussed (Figure 2). Previously identified measures and indicators are developed in this layer, to support the visualization of data at the front end of the dashboard. For this purpose, we used power query M language, DAX, and R programming. Risk calculations of the prediction model were carried out in this stage using R programming.

In the fourth layer, the information requirement of stakeholders is satisfied by visualization and reporting. The front end of the dashboard includes five views namely organizational falls, facility falls, resident falls, medications in detail, and recommendation panel. The filters are applied to various dashboard views depending on user needs as identified during the requirement elicitation and dashboard design stages. Moreover, statistical plots are used to enhance valid comparisons of indicators between facilities and to support decision-making.

Figure 3. The dashboard architecture with four layers. DAX: Data Analysis Expression; PH-FRAT: Peninsula Health falls risk assessment tool.



Dashboard View: Organizational Falls and Facility Falls

The organizational falls and facility falls are accessible by organizational and facility managers. Please note that some information about these views has been removed or modified to deidentify the residents and facility details.

The organizational falls view (Figure 4) includes organizational and facility-level information relevant to fall incidence. The time period and facility names are included as the filters. The information on this view can be updated with the values selected for these filters. The total number of falls along with injuries, and falls that required hospitalization are reported at the organizational level. The funnel plot in the view visualizes the crude fall rate. Users can visualize this plot for the three outcome measures namely all falls, injurious falls, and falls-related hospitalization. Funnel plots with the crude incident rates for each outcome measure enable valid comparisons between the facilities, as it can identify the outlying facilities with higher fall rates related to the number of admissions during the study period. The time series plot with a percentage of injurious falls and a percentage of hospitalization enables the user to investigate overall patterns of falls occurring in selected facilities or at an organizational level. This feature is helpful in identifying the longitudinal trend of injurious falls and hospitalization due to falls in facilities. The time series plot with the most frequent time of falls enables the user to investigate the time pattern of fall incidents. The most frequent locations of falls are linked with the time of falls by a Sankey plot. These plots are dynamic and responsive to the facility selected from the filters. Furthermore, the table with fall risk stages indicates the number of residents within each risk classification predicted by the

embedded predictive model. The most frequent injured body locations are also reported in a table.

The facility falls view (Figure 5) provides more details of the facility-specific falls along with facility characteristics. This view can also be accessed through the organizational level view using the "drill through" functionality in PBI. This view highlights the facility-specific fall rate per 1000 resident days for a specified time. To enhance the interpretability of the predictive model, resident-specific risk factors extracted from the model are reported in this view. Importantly, residents classified under each risk classification along with changes in fall risk compared to the previous day can be accessed in this view for effective fall prevention and management. The view also identifies comorbidities that increase fall risk (eg, dementia) and modifiable risk factors (eg, recent falls within the last six months, frequent locations and times of falls, mobility issues, psychological status, and the use of antipsychotic, opioid, and analgesic medications), all color-coded based on the level of risk identified by the predictive model. Additionally, facility-specific monthly indicators including four national mandatory quality indicators namely the percentage of care recipients: who experienced one or more falls; who were prescribed nine or more medications; who received antipsychotic medications; and with pressure injuries are also reported in this view. This view will also be included in a daily email notification to users once the dashboard is implemented.

Figure 4. Organizational falls view.

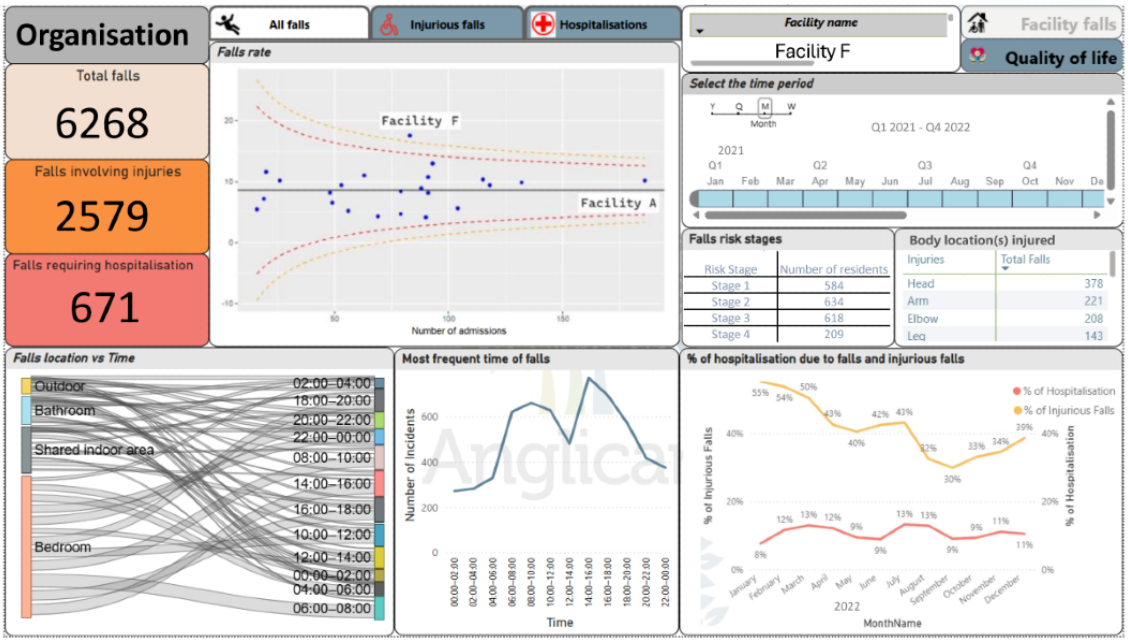


Figure 5. Facility falls view. FRAT: falls risk assessment tool.

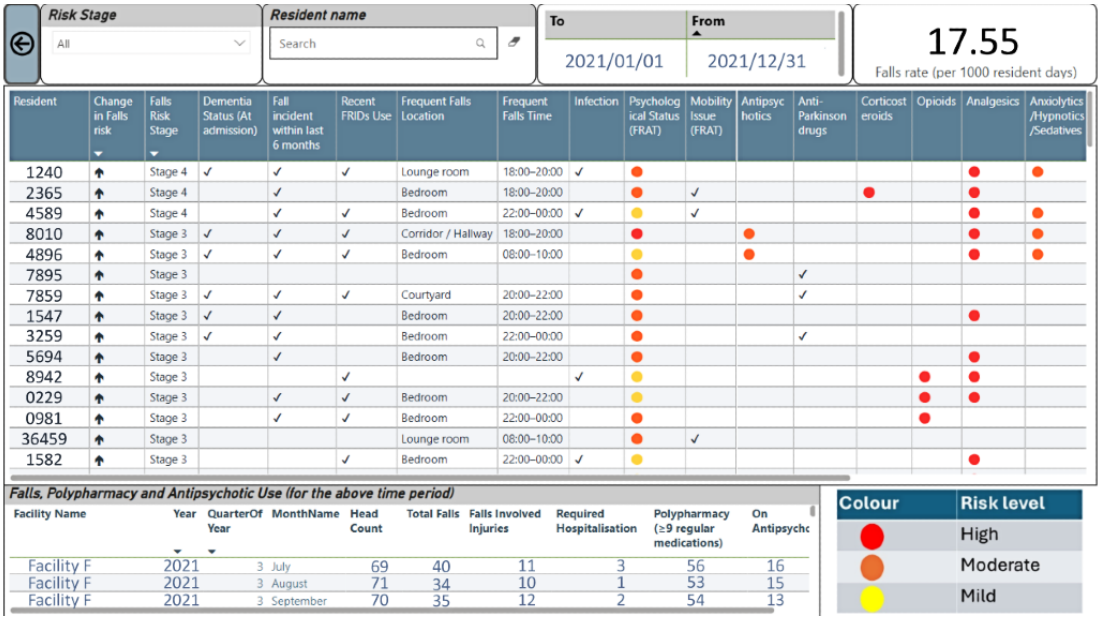
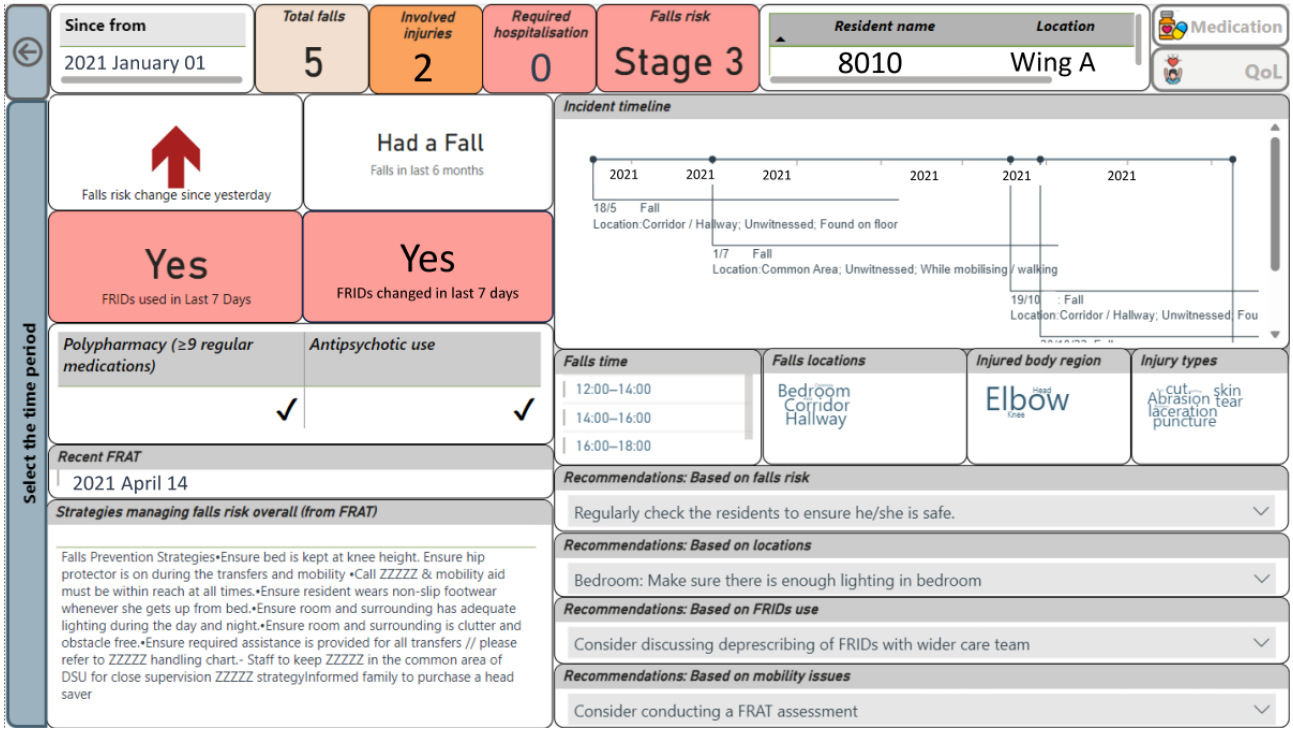


Dashboard View: Resident Falls and the Detailed Medications

Care staff will have access to the resident falls view, which includes the time period, facility name, falls risk classification (ie, derived from the predictive model), and resident identifier as filters.

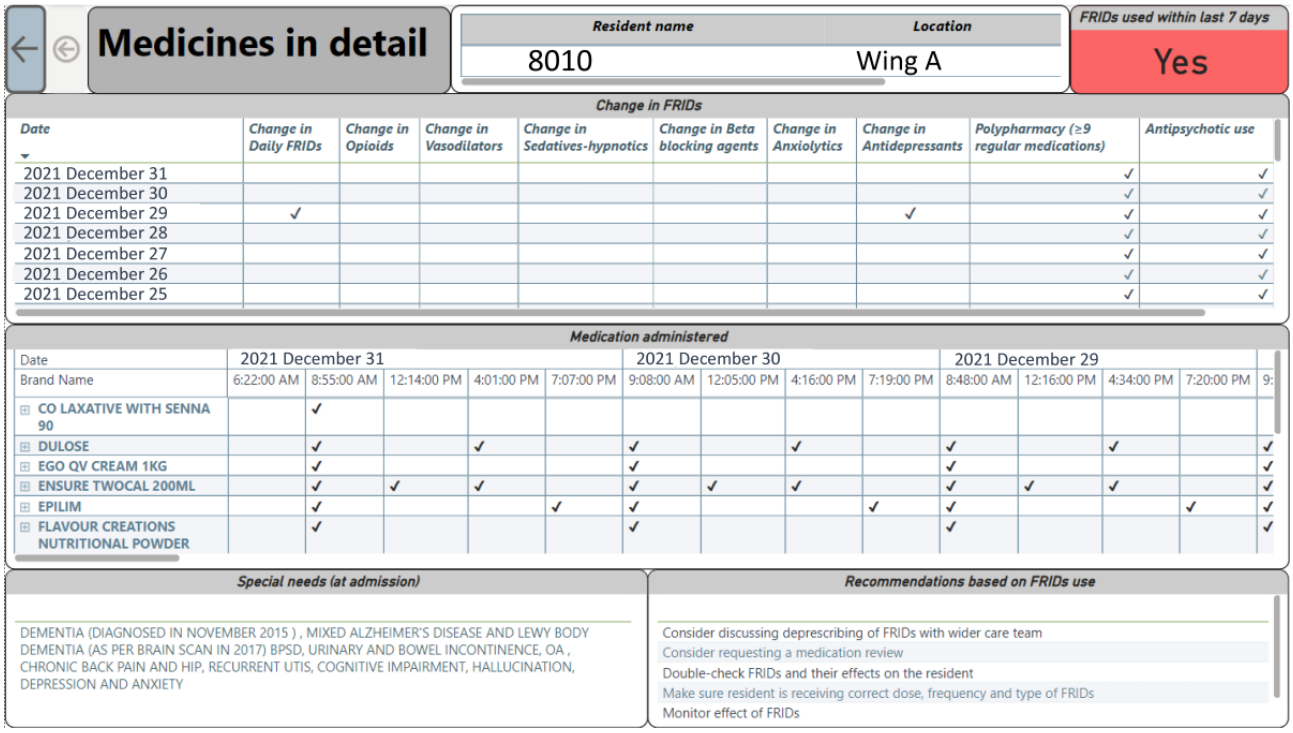
The resident falls view focuses on the resident-specific falls information along with recommendations to prevent falls (Figure 6). This can also be accessed using the facility falls view using drill-through functionality in PBI. The polypharmacy, FRIDs, and antipsychotic medication use are identified using the resident's daily medication administration data. This view presents the current risk category along with the total number of falls faced by the resident during their stay. Risk classification derived from the predictive model is shown using color codes (ie, green to red) and text (ie, stages 1 to 4). Most importantly, the number of falls faced within the last 6 months is shown in this view. Patient-specific fall history is also visualized using a timeline along with the details of the events (ie, event type, injury status, and witnessed or unwitnessed). The sequence and the gaps between the fall incidents are highlighted in this plot. Furthermore, the word clouds visualize the injured body regions, injury types, locations, and time of the falls. At the bottom of the view, personalized recommendations are provided to the resident, which aligns with falls risk categorization, falls history, medication use, and mobility issues.

Figure 6. Resident falls view. FRAT: falls risk assessment tool; FRID: fall risk–increasing drug.



The medications in detail view (Figure 7) focuses on the resident-specific daily medication use. This view can be assessed using the "drill through" functionality enabled in the resident falls view. Here, changes in FRIDs (ie, whether the resident has previously used the drug, whether a medication was omitted, or a new drug added to the medication profile) within the last three days are identified and displayed, along with polypharmacy and antipsychotic medication indicators. The resident's use of FRIDs is highlighted at the top. Daily medication administration records can also be accessed using this view. The special needs (ie, comorbidities and allergies) identified at the admission are included in the view to highlight the comorbidities, special needs, or risk factors of the resident.

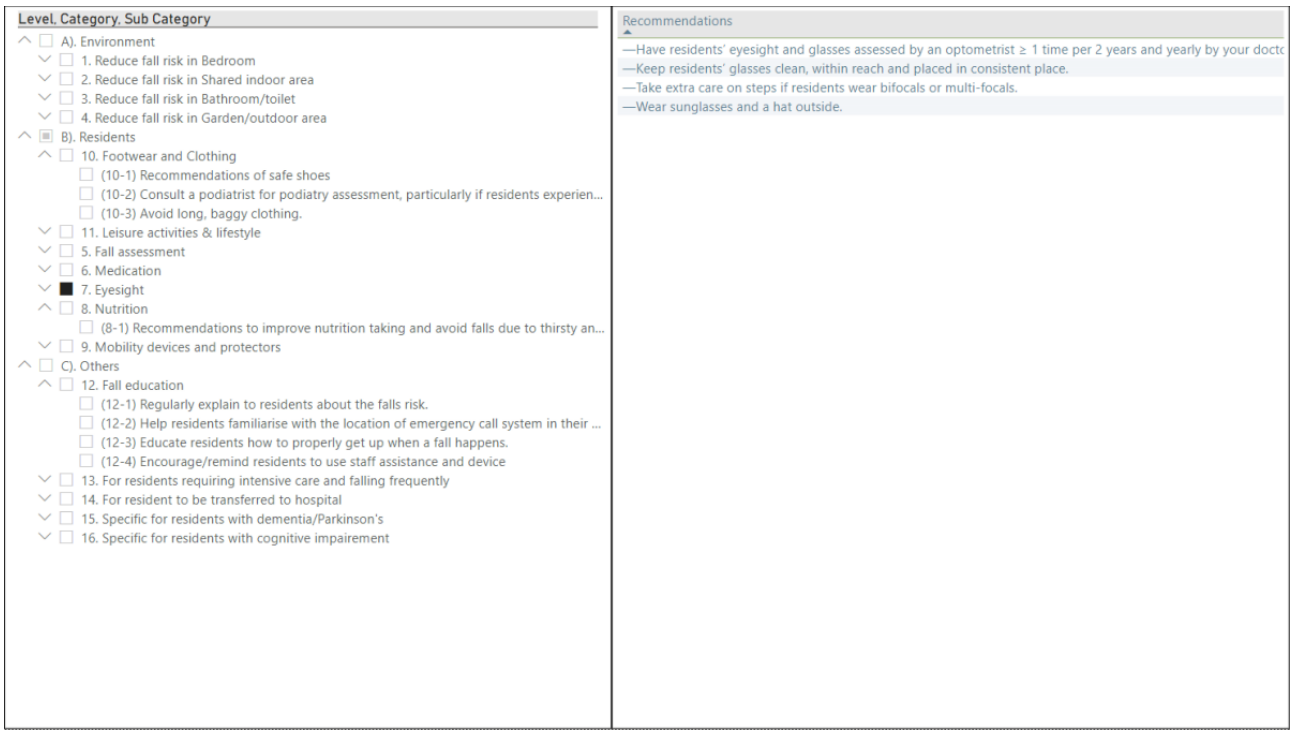
Figure 7. Medicines in detail. FRID: fall risk–increasing drug.



Dashboard View: Recommendation Panel

As falls are affected by intrinsic and extrinsic factors [29], recommendations are grouped and reported in the recommendations panel (Figure 8) in three groups namely: resident (intrinsic), environment (extrinsic), and others followed by subcategorizations.

Figure 8. Recommendation panel.



Illustrative Use Scenario

Organizational Managers

A total of 6268 fall incidents were reported from the 3057 unique residents (729,410 resident days; Table S3 in Multimedia Appendix 1) between January 1, 2021, and December 31, 2021 (Figure 4). Of these, 2579 (41%) falls were injurious and 671 (11%) falls required hospitalization. The average fall rate was 8.36 per 1000 resident days for the study period (funnel plot). The percentage of injurious falls shows an overall gradual decline from 56% to 38%, whereas the percentage of falls requiring hospitalization is stable between 7% and 13% between

January 1, 2021, and December 31, 2021. The majority of falls occurred in residents' rooms. Injurious falls most often involved injuries to the head and face followed by upper limbs. When considering all falls, Facility A reported the highest number of falls. Facility F had the sixth-highest number of falls. However, the rate was above the 99% upper control limit (funnel plot), indicating a higher fall rate (per 1000 resident days) compared to other facilities with a similar number of admissions. Therefore, organizational managers can prioritize Facility F in intervening. They also can select Facility F and drill through to the facility falls view for a more detailed investigation.

Facility Managers

A total of 83 admissions were reported for facility F during the study period, with a fall rate of 17.55 per 1000 resident days (Figure 5). As of December 31, 2021, 3 (4%) residents were categorized with a fall risk of stage 4, while 13 (18%) residents were categorized with a risk of stage 3. Most of these residents had experienced a fall within the last six months and were on FRIDs. The resident bedroom was identified as the most frequent location for falls among the majority of residents. The majority of residents in this facility had cognitive impairment and dementia. It was clear that 54 (77%) and 13 (18%) residents were on polypharmacy and antipsychotics, respectively, for September 2021. Organizational managers and facility managers can use the dashboard information to identify facility-level risk factors and assist them with mandatory quality indicator reporting.

Nurse or Personal Carer

On the facility falls view, a stage 3 resident (ie, resident: 8010) was selected and drilled down to the resident falls view to analyze the resident-level risk factors, fall incident characteristics, and personalized recommendations to prevent and manage future fall risk (Figures 5 and 6). Risk factors: resident 8010 was in stage 3 (as of December 31, 2021) with delirium, dementia, and stroke (Figure 7). The resident was on polypharmacy and antipsychotic medications as of December 30, 2021. There was an increase in fall risk compared to December 30, 2021, which was generated by the embedded predictive model. The resident had five falls during the study period, of which, two were injurious. When considering the resident's incidents timeline, four fall incidents had occurred in the last six months. The resident was on polypharmacy along with FRIDs (as of December 31, 2021) where he had a change in FRIDs in the last three days (ie, December 29-31, 2021). Characteristics of fall incidents: most of these incidents occurred during the afternoon in the resident's bedroom including the hallway and caused injuries to the elbow, head, and knee. The most recent FRAT assessment was conducted in April 2021. Recommendations to prevent future falls: according to the recent FRAT, the identified strategies in managing fall risk were displayed along with prescriptive recommendations such as "regular monitoring," "assessing environmental risk in toilet or bathroom and bedroom," and "assessing FRIDs use."

For a further detailed view of medication use, the resident's medications in detail view (Figure 7) can be assessed. Moreover, carers can use the information provided in the recommendation panel when assessing the fall risk for the resident, based on the resident-level risk factors (eg, dementia), environmental risk factors (ie, bedroom), etc.

Discussion

Principal Findings

Our dashboard adapted and refined the dashboard development process outlined by Staron [10], with an emphasis on understanding the specific domain of residential aged care and their current work practices around fall prevention and management. This was achieved through continuous stakeholder discussions (ie, Stages A and B), quantitative data analysis on the extracted datasets, and reviewing the published literature. This work produces important new resources for the current state of falls prevention in RACFs along with the extent of evidence-based prevention strategies. The dashboard design stage was an iterative process that required close collaboration with the users and its stakeholders (ie, Stage B). This was the most important stage of the dashboard development as it identified the data presentation for dashboard views along with the quantitative measures to be included for fall prevention. To enhance the technology implementation process within the context of fall prevention and management, the four constructs of the integrated Promoting Action on Research Implementation in Health Services framework were followed throughout the dashboard development process.

The core innovation of this study comes from several novel aspects. The Royal Commission into Aged Care Quality and Safety has noted that the residential aged care sector has lagged behind other health care sectors in adopting and implementing technology [30]. It is also found that information systems and processes in these settings are both underdeveloped and inadequately integrated [31]. Furthermore, successfully connecting multiple disparate data sources in aged care is uncommon. This may be due to various factors, such as data being collected by different systems and third-party software vendors being inflexible in incorporating unique identifiers (ie, resident identifiers) across systems. Therefore, this study emphasizes the value of linking existing datasets and visualizing the linked information to support falls prevention. The resident falls view in the dashboard presents the linked data from four data sources and supports to identify resident-level risk factors, fall incident characteristics, and personalized recommendations for fall prevention. This allows users to access crucial information at a glance, rather than navigating across different systems, thus demonstrating significant added value in preventing falls.

The dashboard provides staff with easy access to synthesized, evidence-based recommendations for effective fall prevention strategies. In the dashboard, external evidence on fall prevention and management (eg, published prevention recommendations) has been aligned with current priorities and practices at RACFs (such as PH-FRATs). Current practices, such as the fall prevention strategies identified through PH-FRATs, were embedded, along with rule-based recommendations. Additionally, a separate recommendation panel was established to support decision-making around fall risk assessments.

Another novel aspect of the dashboard is the embedded predictive model. Predicting fall risk is challenging because of the numerous contributing factors [32,33], including medical conditions, medications, functional status, behavior, physiological aspects, and environmental conditions. Many of these factors, such as medication use, can vary over time [34]. The dynamic predictive model embedded in the dashboard is therefore an important part of the dashboard. It uses near real-time data and helps to classify the resident risk of falls on a daily basis. The incorporation of the predictive algorithm in the dashboard goes beyond what has been possible with existing fall risk assessments as it dynamically predicts the risk and links it to residents' fall risk factors and personalized strategies. This provides timely and meaningful risk prediction along with evidence-based recommendations based on resident profile, to the caring staff to facilitate person-centered fall prevention and improve outcomes.

Finally, the dashboard is innovative because it adopts a holistic approach to managing falls in aged care residents by integrating multiple data sources and making this information easily accessible to different stakeholders including managers and carers. The granular resident-level data are aggregated to the facility and organizational levels, allowing users to navigate seamlessly between these levels with just a few clicks. This structure enables users to drill down from the organizational level to individual residents or vice versa, providing a comprehensive and detailed view of fall risk and prevention strategies.

Challenges Faced and Strategies to Overcome

There were many challenges faced when developing this dashboard. Initially, the dashboard was developed using datasets that were extracted from the provider rather than directly connecting to the database. This leads to the integration process becoming more challenging unless the variables are in standard format as in the database. Moreover, our partner has changed its incident reporting system and daily medication management system within the development process. More robust processes were required to be implemented on the backend of the dashboard to overcome these challenges. The data acquisition layer discussed in dashboard architecture was important in this aspect. This layer acts as a data reservoir. Here, the initial data are extracted from original sources, stored in the original format, and then transformed into the data tables that the dashboard requires. This layer enabled the dashboard to be sustainable in the long run amid the underlying system changes.

The data model in the backend of the dashboard also plays a critical role in facilitating the above process. This is crucial as the measures were developed using the linkages between the tables. Adapting a star schema as much as possible within the dashboard backend has promoted several advantages within the study. Simplicity and ease of use of the data model during various stages of the development process can be noted. Visualization and embedding of analytical measures within the dashboard were simplified without complex data integration. This has streamlined the dashboard development during the co-design stage while accelerating the time of incorporating various views on fall prevention and management. Flexibility and scalability can be noted as another advantage where the schema was helpful in adapting the dashboard design to changing RACF requirements in managing falls while incorporating additional data fields and sources with minimum modifications to the existing structure. Therefore, overall, adapting the star schema as much as possible within the dashboard development process was an excellent choice due to its ability to incorporate changing user requirements in the context of fall management at RACFs.

Furthermore, for the daily calculation of changes in fall risk, this study uses R programming. This decision stems from PBI's inability to retain and save daily risk calculations. To address this limitation, the designers have integrated R programming code into the Power Query Editor, enabling the storage of these risk calculations on a shared drive. The code automatically saves these calculations on a daily basis during the data refresh cycle, occurring every 24 hours. Subsequently, on a daily basis, these stored files (ie, previous-day risk calculations) are retrieved into the PBI backend to calculate the difference between current and previous risks at the resident level.

The integration of R programming into the dashboard backend has introduced a technical skills gap between the partner organization and the dashboard designers. Consequently, workshops were organized with the partner organization's IT teams to provide training on R programming, bridging the gap in statistical analysis using R programming. Additionally, line-by-line code interpretation was incorporated into the embedded codes to facilitate a seamless transition during dashboard implementation.

Implications for Policy, Practice, and Future Research

This study highlights the potential of using a fall prevention and management dashboard to enhance resident outcomes in aged care through the effective use of information systems. Health dashboards facilitate decision-making and are required to be used in conjunction with clinical judgment, staff education, training, and individualized tailored responses. Future policy and practice must ensure the interoperability of information systems in aged care, involve key stakeholders in development and implementation, and allocate appropriate funding for these processes. Future research should also focus on expanding the fall prediction dashboard and incorporating other care needs in residential aged-care facilities, such as hospitalization and wound management.

Conclusions

In this study, a comprehensive process for developing a fall prevention and management dashboard with descriptive, predictive, and prescriptive analytics for RACFs was thoroughly discussed along with a sustainable architecture. The key focus was to provide a holistic approach to managing falls by linking existing data sources at the provider level. This highly applied and translational research demonstrated how EHRs can be used along with technology to deliver evidence-based information to aged care allied health workers and managers, to drive better aged care quality and safety.

Acknowledgments

We thank our partners and collaborators including Anglicare, Northern Sydney Local Health District, Sydney North Primary Health Network, the Deeble Institute for Health Policy Research, and the Australian Aged Care Quality and Safety Commission.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the privacy of the individuals who participated in the study but are available from the corresponding author upon reasonable request.

Authors' Contributions

The dashboard was technically designed by SSMS. The co-design process of the dashboard involved SSMS, NW, ADN, KS, LD, IM, CIM, and GH. The manuscript was drafted by SSMS and revised by NW, ADN, KS, GH, and IM. Both the manuscript draft and system were reviewed by JIW.

Conflicts of Interest

Abstract

Background: Game-based cognitive assessments (GBCAs) have the potential to transform the field of cognitive testing by enabling more effective screening of age-related cognitive decline. However, we lack a strong understanding of the usability and overall user experience of these games. This is a risk because the primary target users for GBCAs, older people, are seldom involved in game design research and development.

Objective: This study aims to address this gap by investigating the usability, acceptability, and enjoyability of GBCAs for older people.

Methods: This study followed established practices for undertaking evidence-based systematic reviews.

Results: The initial database search returned 15,232 records. After a thorough screening process, 8 studies remained for extraction and analysis. A synthesis of the included papers identified 2 overlapping yet distinct areas of focus: system usability and subjective user experience. Usability scores were mostly positive across the studies included. However, in several of the game studies, older adults and those with cognitive impairment tended to find GBCAs less usable. This trend was observed even when the games were explicitly designed for these populations, and the tasks were simplistic and representative of basic daily activities. In our second focus area, user experience, we identified the importance of perceived challenge in mediating gameplay experience across groups. That is, generating the appropriate level of difficulty for each user is important for positive user experiences, specifically enjoyment.

Conclusions: On the basis of these findings, we identified key learnings for researchers interested in designing and developing GBCAs. These include (1) recognizing that validity is essential but not sufficient on its own; (2) clearly defining the intended user; (3) designing games that align with the unique preferences and needs of older people; and (4), whenever possible, providing each user with their optimal level of challenge.

serious games; gamification; cognitive assessment; usability; user experience; aging

Introduction

Background

In recent years, there has been growing enthusiasm about the use of serious game–based technology. The primary objective of these games is to increase user engagement and motivation, thereby offering people a more pleasant environment to complete "serious" objectives that go beyond entertainment [1]. One area identified as being particularly well suited to the application of serious game technology is the field of cognitive assessment [2].

Serious games for cognitive assessment have typically been developed in 1 of 2 ways [3]. The first is "gamification," the process of building game-like features onto a cognitive task. This includes adding points, time limits, or appealing graphics to the foundational design of a traditional task. The second is to create or use an "actual" game, where the entire environment has been purposefully designed to be a game. This approach, more commonly associated with the term *serious game*, offers more creative development options, player choice, in-game competition, overarching narratives, and integrated or blended design elements. This approach is commonly based on theories of cognition or reimagining commercial games rather than reproducing a traditional cognitive task [3]. However, there remains significant confusion and inconsistency across the literature regarding what constitutes a serious game versus a gamified task. Therefore, unless otherwise noted, this paper refers to both approaches collectively as game-based cognitive assessments (GBCAs).

Traditional Cognitive Screening and the Case for Change

Traditional cognitive assessments are used by health professionals to evaluate a person's cognitive, or "thinking," functions to identify cognitive impairments or age-related declines, such as Alzheimer's disease (AD) [4,5]. Most clinicians initially use short cognitive screening tests (eg, 10-15 min) when assessing these functions. Although there are clear and well-evidenced benefits of using traditional cognitive assessment and screening tools (eg, the Montreal Cognitive Assessment has been shown to have high sensitivity [6]), there are also several issues that reduce their overall effectiveness. One concern often cited by users is that traditional screening tests can be boring and repetitive, thereby reducing user motivation and engagement during assessment. This is problematic because data obtained from individuals who are not motivated to perform a task to the best of their abilities may not be representative of their optimal performance, and this can cause misleading performance data (eg, false positives) [1]. Brief assessment tools also lack ecologic validity, meaning tasks may not translate to real-life circumstances [1,3,7]. In addition, assessments can sometimes create feelings of shame and distress [8]. Consequently, some people report significant test anxiety as well as self-stigma related to low literacy or education levels when completing cognitive tests [9,10]. Another limitation is the concerning association between cognitive performance and education level found with many screening tools [5]. Finally, some widely used neuropsychological tests are not culturally appropriate [11].

An initial attempt to address some of the concerns with traditional screening methods included digital software suites, such as CogTest and the Cambridge Neuropsychological Test Automated Battery [12]. Although these tools enable more consistent assessment and data capture, they are essentially digitized versions of traditional cognitive tests and, thus, are not gamified. Tests of this nature have encountered validation issues [12] as well as similar problems to traditional testing, such as a lack of user motivation when performing somewhat uninteresting tasks on a computer [2].

GBCAs Offer Exciting Alternatives, but They Must Be Valid, Acceptable, and Motivating

Games have recently been seen as a viable alternative to address many of these issues and improve both testing engagement and validity [1,2,12]. The benefits of using GBCAs include increased participant motivation and engagement relative to traditional tasks [2,3]. GBCAs can also offer shorter, more cost-effective, and scalable assessments [13,14]. Unlike traditional "pen-and-paper" assessments, games do not need to be initiated by a care provider and can be designed for self-administration or delivery by nonclinicians [1,14]. In addition, they may support more ecologically valid assessment through realistic context and gameplay, thereby engaging cognitive processes in ways that closely mirror real-life situations [15,16]. GBCAs can also enable consistent tracking of an individual's cognitive performance data to support the detection of subtle changes or variations in cognitive processes over time [14]. The richness of this type of data can provide invaluable population-level insight into subtle aggregate patterns, changes, or important impacts (eg, effects of exercise or smoking) on cognitive health across groups. This is an especially attractive prospect, given the increasing sophistication of machine learning models.

However, to justify their use, GBCAs must function as effective and reliable cognitive assessment tools (ie, psychometrically validated) while also being usable, acceptable, and motivating. Much of the current literature on GBCAs assumes that the simple process of gamification improves user engagement and creates a more satisfying and less tedious experience than traditional pen-and-paper or digitized neurological tests. Although many games have been found to achieve this [1-3], this is not always the case. For instance, Birk et al [17] found that adding game elements to standard cognitive tests (eg, go/no go; n-back tasks) did not improve user engagement when compared with the original task. Gamification actually reduced test performance for the go/no go task. Tong et al [18] reported difficulties in testing a carnival whack-a-mole game with older

users, also based on the go/no go paradigm, because of ergonomic issues with mobile and touchscreen devices (eg, the difficulty holding a touch device). It is also important to recognize that there may be restrictive settings or social contexts where GBCAs may be impractical, and traditional approaches may be more appropriate.

Overall, when games are not appropriately designed for their target users or contexts, they risk being neither acceptable nor motivating. Similarly, games might be skillfully designed and psychometrically validated but not adequately evaluated from users' perspectives. A systematic review of game-based interventions for neuropsychological assessment, training, and rehabilitation found that user experience evaluation was performed in <25% of interventions, with usability and enjoyability assessed in only 13% and 18%, respectively [19]. For a technology specifically aimed at increasing user engagement and enjoyment, this lack of user design input and evaluation appears to be a barrier to achieving the technology's intended outcomes.

GBCAs for Older Users

The group of interest for this study is older people (aged ≥50 years) who have or may be at risk of cognitive decline and, consequently, neurocognitive disorders (eg, dementia, such as AD). Recent research on aging has suggested that groups considered marginalized (eg, people experiencing homelessness or incarceration) are at risk of age-related conditions, such as frailty and cognitive impairment [20,21], once they reach the age of 50. Thus, to ensure adequate inclusion of people considered marginalized who are at risk of cognitive decline, we define older people as those aged ≥50 years.

Concerns about user engagement are exacerbated for game assessments aimed at detecting cognitive decline such as dementia because the target group for such tests is typically older people. This represents a challenge because games are rarely designed for or tested with older people. By contrast, there is promising—but preliminary—research to suggest that people who either have or are at risk of cognitive decline can play, attend to, and enjoy digital games, even when they do not have previous experience with touchscreen devices [22]. However, their ability to successfully complete gamified tasks appears to depend on the specific application and mechanics used within a game [22]. More broadly, the game preferences of older people seem to be different from those of younger cohorts, with studies reporting the preferences of older users gravitating toward intellectually stimulating games (ie, puzzle, educational, and strategy games) [23] that enable them to compete for high scores, require only a single player, and emphasize intellectual challenge over quick reflexes [22]. According to Blocker et al [24], games with violent content, fantasy characteristics, or interactive web-based components are not preferred by older users. A qualitative study investigating the cognitive game preferences of older people in prison reported similar findings [25], with participants suggesting a need to avoid "childish" game design, which some found condescending.

The Useful Concepts of Usability and User Experience

Across the design literature, usability and user experience are cited as major determinants of the successful adoption of any information system. Therefore, both are useful concepts when considering the acceptability, motivation, and engagement generated by any GBCA. Usability is the capacity of an object (ie, a digital game-based application) to functionally serve its intended purpose (ie, valid cognitive assessment) through qualities ranging from technical efficiency to conformity and configuration to ease of use [26]. According to the International Organization for Standardization (ISO: 9241-210:2019) [27], this refers to "the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use." According to Hassenzahl and Tractinsky [28], usable systems or products enable users to achieve pragmatic objectives successfully and efficiently without obvious barriers.

On the other hand, user experience refers to the feelings a person has while interacting with a product under particular conditions [26]. This means that it goes beyond meeting the instrumental (pragmatic) need for usefulness and efficiency that good usability provides. User experience includes the need to achieve hedonistic goals [28,29], which involve "users' emotions, beliefs, preferences, perceptions, comfort, behaviors, and accomplishments that occur before, during and after use" [27]. Although there is a clear overlap, the distinction between the concepts is that good usability makes it easy for someone to use something, whereas good user experience makes using that thing feel enjoyable or satisfying.

In the context of gamified technology, usability is focused on technical features such as a seamless interface, ergonomics, clear instructions, minimal in-game bugs or errors, and other features that facilitate use, whereas user experience is concerned with impacting a person's subjective experience about the contents of a game, that is, a compelling narrative, an exciting challenge, motivation toward certain objectives, and so on [26]. There are more detailed and stratified definitions of usability and user experience across the user design literature (eg, refer to the 10 Usability Heuristics for User Interface Design by Nielsen [30]). However, consistent with our simplified definition of GBCAs, we intentionally use the basic demarcations of usability and user experience defined earlier to enable a consumable preliminary synthesis and analysis of this still-developing area of inquiry (ie, user evaluations of GBCAs for older people).

Arguably, the critical success factor for any GBCA is a coupling of user evaluation and psychometric validity. This is particularly true for older people at risk of, or presenting with, cognitive decline who are likely to have different preferences and experiences from other cohorts. However, much of the current literature is skewed toward investigating psychometric validity before or without evaluating usability and user experience. For instance, although several reviews in recent years have investigated GBCAs [2,3,31-34] and some have reported summary results on user evaluation methods (ie, how many studies conducted user evaluation) [19,35], there remains a limited understanding of the importance of user evaluation

findings. This appears to be a risk, as even the most clinically useful game in the world is unlikely to succeed at scale if it is neither functional nor engaging.

The Aims of This Study

This systematic review attempts to address some of these concerns by investigating the usability, acceptability, and enjoyability of GBCAs that have undergone psychometric validation. The intention is to better understand the nexus of clinical usefulness, usability, and user experience and, in turn, report preliminary lessons learned from user evaluations of validated GBCAs.

Methods

This study (protocol registered on PROSPERO [CRD42023433298]) followed established practices for undertaking evidence-based systematic reviews, including the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist (Multimedia Appendix 1) and the Scottish Intercollegiate Guidelines Network methodology checklist for study quality appraisal (Multimedia Appendix 2 [16,36-43]).

Data Collection, Extraction, and Quality Assessment

Independent and systematic database searches of PsycINFO, Embase, IEEE, and MEDLINE were conducted by the first author (RM) based on the predefined search terms summarized in Table 1. Broad search parameters were set, given the disparity of terminology used across the GBCA research. Relevant studies were then imported into Covidence, ready for initial screening. Title screening was manually completed by RM, where obvious exclusions and duplicates were removed. Duplicates were removed automatically via Covidence's duplicate removal function. This was followed by independent and systematic screening of relevant abstracts by 2 reviewers (RM and MD), who applied predefined inclusion and exclusion criteria to assess all abstracts.

Table 1. Database search terms. Note: the truncation symbol * (asterisk) searches for multiple variants of a word (eg, singular, plural, different conjugations, etc) all at once (eg, cogn* includes searches for cognition, cognitive, cognitively, cognizant, etc). MCI: mild cognitive impairment; VR: virtual reality.

Topic area	Search terms
Serious games	game* OR gami* OR virtual reality OR VR
	AND
Cognitive	cogn* OR MCI OR dementia OR neurocog* OR neuropsych*
	AND
Assessment	assess* OR test* OR measur* OR collect* OR detect*

Textbox 1 presents the inclusion and exclusion criteria. Important definitions and justifications relating to the inclusion and exclusion criteria are discussed more thoroughly in the Discussion of important terms subsection. When disagreements arose at the abstract screening level, the second author (YIJH) facilitated a resolution through a 3-way vote. Full-text screening was then conducted by RM and MD. Conflicts at this stage were again handled through 3-way voting consensus involving YIJH, RM, and MD. At the full-text screening stage, there were disagreements with 12 (15%) of 83 papers, which necessitated additional consensus voting. Finally, a thorough data extraction process was conducted by RM, including a risk of bias assessment. We used the Scottish Intercollegiate Guidelines Network "Methodology Checklist 4: Case Control Studies" [36] guidance to assess the risk of bias for each included study. A detailed risk of bias assessment can be found in Multimedia Appendix 2. This final extraction process was reviewed by all authors to ensure consensus and quality control.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- User evaluated
- People aged ≥50 years
- Psychometrically validated
- Assessment or screening
- Cognitive functioning
- Primary research
- 2015 onward
- Digital serious games and gamification of task

Exclusion criteria

- Did not include target population or outcome
- Intervention with high immersion (via head-mounted display, etc)
- Training or rehabilitation focused without assessment
- No psychometric validation
- No user evaluation
- No data collection performed (ie, game performance data not collected)
- Inappropriate study design (reviews, conference abstracts, etc)
- Focus on social cognition only

Discussion of Important Terms

This section summarizes and justifies several key concepts relevant to our inclusion criteria in Textbox 1, as well as our overall search strategy. It is important to emphasize that (1) our search strategy was intentionally broad to minimize the risk of missing any relevant GBCA studies and (2) our inclusion criteria were intentionally narrow to address our research aim of investigating the usability, acceptability, and enjoyability of GBCAs that have undergone psychometric validation.

User-Evaluated Study

The key criterion in this review was that a GBCA must have been user evaluated through primary research. This required the explicit inclusion of methods to measure usability, user experience, user motivation, user preference, enjoyment, or acceptability of the game.

GBCA Overview

Our definition of GBCA mirrors the broad definition included in the Introduction section. That is, both simple task gamification and more “from scratch” serious games were included. In addition, our focus was technology-based GBCAs; thus, we only included digital GBCAs (ie, games that could be played on computers, tablets, phones, etc).

Target Group

The target group for this review was older people (aged ≥50 years) who had, or were at risk of, cognitive decline and, consequently, neurocognitive disorders (eg, dementia, such as AD). Although there are numerous GBCAs that have been designed and tested to detect cognitive impairment associated with other disorders across the life course (eg, attention-deficit/hyperactivity disorder, depression, traumatic brain injury, drug- and alcohol-related cognitive deficits, etc), this paper is interested specifically in the assessment of cognitive decline in older people. This demarcation enables a manageable and specific grouping of findings.

Validated Study

To be included in this review, a GBCA must have been psychometrically validated with a sample of older users (aged ≥50 years). This validation could have occurred in the same study as the user evaluation or in a previous validation of the same game. In other words, evidence of validation was a prerequisite for inclusion in this review, but validation of the game was not necessarily required within the actual studies included in this review. According to previous definitions [3], validation included comparisons against a traditional cognitive screening tool (eg, Montreal Cognitive Assessment), a comprehensive neuropsychological battery, or a previous clinical diagnosis of cognitive impairment.

Cognitive Domains Included

A broad definition of cognitive functioning was applied for this study. Cognition refers to the brain’s ability to perceive, assimilate, organize, store, and manipulate information [44]. As such, cognitive functioning is an umbrella term that encompasses a range of integrated skills and domains that allow us to process and respond to information within our environment [44]. These domains include (but are not limited to) basic functioning (eg, processing speed and attention) and memory (eg, episodic memory, semantic memory, and prospective memory), visuospatial functions (eg, color perception and mental

rotation), and executive functions (eg, planning, and decision-making). Relevant GBCAs testing any (or all) of these domains were included in this review, with the notable exception of social cognition. The clinical assessment of social cognition and decline in older people is not as well established as these other cognitive domains and was therefore intentionally excluded. However, investigating social cognitive domains should be seen as a critical consideration for future research.

Low-Immersion Interventions

This review made a distinction between low- and high-immersion games when deciding if a study should be included. Games that were deemed highly immersive from a technological perspective, such as those requiring headset technology and immersive 3D environments, were excluded. This review focused on GBCAs in a digital format that enabled accessibility through touch or mouse click capability. The main reason for this distinction was to ensure uniformity in findings. Although highly immersive games have significant potential benefits with respect to ecologic validity and integrated assessment of multiple cognitive functions [45], they have distinctive technology requirements when compared to computer or tablet-based game systems. In addition, factors such as motion sickness [46], which can affect enjoyability, are specific to virtual 3D headset environments and would have added unwanted complexity to this synthesis. Importantly, due to the disparity in the definition of serious games, gamification, and virtual reality across the literature, some interventions have been included in this review even when the authors refer to their interventions as *3D* or *virtual reality* game applications. However, these interventions aligned with our definition of a tablet-based and low-immersion GBCA and were thus included.

2015 Onward

There is limited literature before 2015 that investigated games that were both psychometrically validated and user evaluated. There are 2 notable reviews that looked at validity before 2015 [2,34], but these reviews concluded that little work had been done in user evaluation of GBCAs before this time. In addition, a preliminary scan of literature before 2015 by the first author confirmed a lack of usability data from psychometrically validated games. Given our very broad search strategy, the significant growth of literature on GBCAs in the last 5 to 7 years, and a lack of user evaluation data before this time, a cut-off of 2015 for selection appeared justified.

Results

Overview

The initial database search on December 9, 2022, identified 15,232 records. There were 7595 articles left after removing duplicates. A total of 6946 articles were removed during the title screening for obvious exclusions, leaving 649 articles for abstract screening. Full texts were retrieved for 83 articles, of which 8 studies remained for extraction and analysis. More detail is provided in the PRISMA flow diagram in Figure 1, including reasons for exclusion at the full-text phase. The key study characteristics for all included papers are presented in Table 2. A summary of key psychometric validation results can be found in Multimedia Appendix 3 [15,47,48]. All studies included psychometric validity testing as part of their analysis except the Virtual Supermarket Test (VST) [37], where validity testing had been completed previously [15,47,48]. All games were designed and developed by the researchers involved in the included papers, with the exception of the Smart Aging Serious Game (SASG) [38], which was developed by Zucchella et al [49]. None of the included papers involved testing commercially available games; however, 2 of the games [39,40] were experimentally controlled versions of existing games. In addition, 4 of the 8 game studies were noted by the authors as being “virtual reality” interventions, which attempted to replicate real-life activities to assess cognition. However, all these games had low immersion and adhered to our definition of a digital GBCA (refer to the Discussion of important terms subsection for further justification).

Figure 1. PRISMA flow diagram.

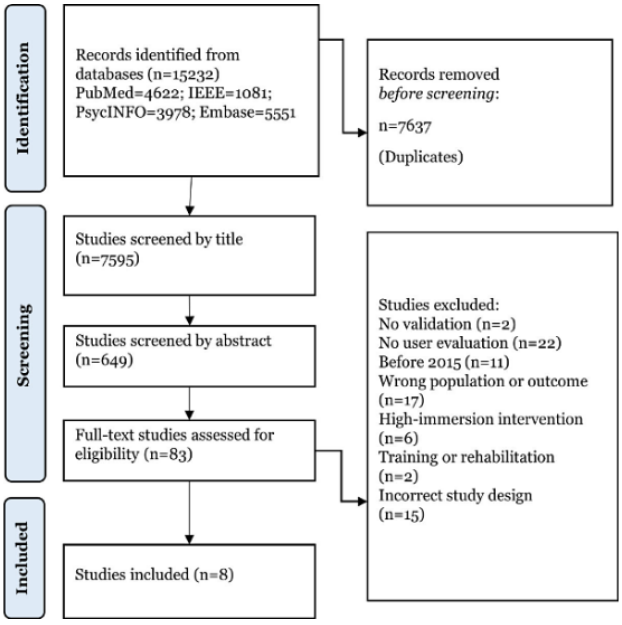

Table 2. Summary of key study characteristics.

Studies	Game	Sample, n	Age, mean	Female (%)	Study aim
Cabinio et al [38], 2020	SASG[a]	Total: 139; controls: 107; MCI[b]: 32	Controls: 76.47; MCI: 76.75	Controls: 49.5; MCI: 46.8	Tested the usability of SASG in a cohort of participants with MCI and determined the validity of the SASG in discriminating between a preclinical population with MCI and healthy controls.
Chesham et al [40], 2019	SMT[c]	Total: 52; young (18-35 y): 28; older (65-85 y): 13; oldest (≥85 y): 11	Young: 21.68; older: 70.54; oldest: 89.27	Young: 71.4; older: 53.9; oldest: 81.8	Examined the initial validity and usability of an experimentally controlled version of a popular TMM3 puzzle video game—the SMT.
Manera et al [41], 2015	Kitchen and Cooking	Total: 21; MCI: 9; AD[d]: 12	MCI: 75.8; AD: 80.3	MCI: 77.8; AD: 86.7	Conducted a feasibility study of patients with MCI and AD and related disorders using the game "Kitchen and Cooking."
Nef et al [39], 2020	Numberlink puzzle task	Total: 55; young (18-31 y): 18; older (64-79 y): 14; oldest (86-98 y): 14; PD[e]: 4; HD[f]: 5	Young:21.83; older: 71.4; oldest: 89.4; PD: 67.5; HD: 49.4	Young: 66.7; older: 57.1; oldest: 85.7; PD: 50; HD: 50	Evaluated the feasibility and preliminary validity of a maze-like NL puzzle video game as a tool to assess cognitive and motor differences in adults and patients with neurodegenerative disorders.
Valladares-Rodriguez et al [16], 2017	Episodix	Total: 16; controls: 8; MCI: 3; AD: 5	Controls: 68.3; MCI: 75.8; AD: 75	Total: 75	Investigated if a video game could be designed and developed to assess episodic memory and predict early cognitive impairments in an ecologic setting with low immersion.
Vallejo et al [42], 2017	Virtual games	Total: 38; controls: 20; AD: 18	Controls: 74.6; AD: 77.8	Controls: 40; AD: 50	Evaluated the usability and the screening potential of several low-immersion virtual game tasks for patients with AD.
Wang et al [43], 2022	GBCA[g]	Total: 124; controls: 57; NCDs[h]: 67	Controls: 72.31; NCDs: 74.78	Controls: 69; NCDs: 63	Developed a game-based tool and evaluated its validity as an early screening for patients with cognitive impairment.
Zygouris et al [37], 2022	VST[i]	Total: 57; SCD[j]: 24; MCI: 33	SCD: 65.58; MCI: 68.39	SCD: 79; MCI:70	Assessed the VST's usability in a sample of older adults with MCI and SCD. The paper analyzed how usability is affected by age, education, diagnosis, in-game performance, and familiarity with touch devices.

[a]SASG: Smart Aging Serious Game.

[b]MCI: mild cognitive impairment.

[c]SMT: search and match task.

[d]AD: Alzheimer's disease.

[e]PD: Parkinson disease.

[f]HD: Huntington disease.

[g]GBCA: game-based cognitive assessment.

[h]NCD: neurocognitive disorder.

[i]VST: Virtual Supermarket Test.

[j]SCD: subjective cog decline.

User Evaluation Findings

Overview

Preliminary analysis of the included papers identified 2 distinct areas of focus: usability and user experience. As such, our proceeding synthesis is demarcated based on usability and user experience (applying the simple definitions of these constructs provided in the Introduction section). Reporting findings from these 2 overlapping yet distinctive areas provides a holistic perspective of user evaluation by incorporating both system-level usability results as well as more individualized user experiences of serious gameplay. A detailed overview of relevant study findings and key statistical results is presented in Multimedia Appendix 4 [50-56].

GBCA Usability

A total of 5 studies [37-40,42] included system-level usability results. All these studies involved participant self-report measures but varied in the level of detail participants were asked to report. Overall, the average usability, from a systems perspective, of the games presented ranged from good to excellent. Familiarity with computers or touch screens did not appear to have a significant effect on system usability for computers or touchscreen devices, which is a positive finding. However, there were distinct differences in system usability across age groups and cognitive functioning levels in some

studies. An interesting relationship was also found between usability and game performance in the VST study [37]. These are discussed further in the subsequent sections.

In the SASG study [38], participants were simply asked to respond to some questions about their familiarity with computers and touch screens. Results showed that familiarity with computer systems did not influence the SASG game performance score. Although this is not in itself an assessment of usability, it revealed an important usability finding: a lack of digital experience did not impact overall cognitive performance scores in a sample of older game users with low digital literacy and experience. A potential reason for this result may be the cautious and simplistic design of the SASG interface, which supported usability for the target cohort. The game was built specifically for older and nonexpert users, and according to the authors, it did not require skilled digital abilities. Using a low-immersion, first-person perspective, the game required users to complete gamified versions of everyday tasks, such as watering flowers with the radio on and dialing a phone number. Furthermore, the authors suggested a key factor in the usability of their serious game intervention was the decision to use a touch screen instead of a mouse.

The remaining 4 studies used the system usability scale (SUS) to measure and analyze usability [57]. The SUS is a brief questionnaire (10 questions) using a 5-point Likert scale with a possible aggregate score ranging from 0 to 100. The SUS includes questions such as "I thought the system was easy to use" and "I needed to learn a lot of things before I could get going with this system." According to previous studies [58,59], the average SUS score (50th percentile) is 68, a good score is between 71 and 84, and an excellent usability score is ≥85.

In the VST study [37], the average SUS score was 83.11 (SD14.6). No statistically significant differences were found between the participant groups, people with subjective cognitive impairment and mild cognitive impairment (MCI), regarding SUS scores. However, there was a significant correlation (r=−0.496; P<.001) found between the SUS score and the average time needed to complete the VST test trials, independent of the participant group. This suggested a relationship between game completion and usability: the lower the participants rated the game's usability, the longer they took to complete it. Although this was an interesting finding, the direction of causality is unknown. As the authors noted [37], "It is unclear whether participants who took longer to complete the VST test trials provided a lower usability score as they were frustrated by the long time it took them to complete the exercise or if there are underlying usability issues that affected their performance thus resulting in a longer time to complete the VST test trials." It is also worth noting that in the VST study, participants were asked to complete the VST exercise on their own. The examiner prepared the tablet and launched the VST game but did not assist the participants. In fact, researchers intentionally provided little support to participants once gameplay started. The reason for this was to assess the usability of the system in an environment where a user may need to self-administer the game without support.

In the Numberlink (NL) puzzle task [39], the SUS average was 93.38 (SD 5.72) for young adults, 93.33 (SD 6.25) for older adults, 83.39 (SD 11.79) for the oldest adults, 81.88 (SD 9.66) for people with PD, and 83.12 (SD 10.68) for those with HD. These scores reflected a statistically significant difference in usability ratings between groups (P=.02). There were similar findings in the search and match task (SMT) study, albeit with lower reported usability overall [40]. The average SUS score was 88.67 (SD 7.28) for younger adults, 79.09 (SD 15.50) for older adults, and 68.25 (SD 18.78) for the oldest adults. This indicated a significant effect of age group (P=.01), with usability ratings decreasing with increasing participant age. Finally, the virtual game study [42] reported a mean SUS score of 83.5 (SD 11.16) for the control group and 83.75 (SD 9.82) for people with AD. As such, similar to the VST study and contrary to the NL puzzle task and SMT studies, there was no significant group difference found in usability. There was also no significant difference in SUS scores found between participants with and without touch device familiarity.

GBCA User Experience

Five studies [16,39-41,43] examined user experiences of gameplay, specifically focusing on participant engagement with game elements, perceived motivation, and enjoyment. Overall, all the games presented were well received by users regarding motivation, enjoyability, and satisfaction. However, there were some important differences across the study findings. For instance, some studies identified a relationship between being cognitively healthy and improved user experience [40,43], whereas an opposite relationship was found in another study [41]. Furthermore, 2 studies identified the role of a health professional as essential to the success of their respective game interventions [16,41], which contrasted with the intent in studies to test implementing games in a self-administering environment [37,41].

In the Episodix study [16], a user experience questionnaire based on game usefulness and user motivation was completed by participants. The questionnaire was completed twice, once before and once after gameplay. Before playing the game, most participants reported low interest, motivation, and perceived usefulness of serious games; however, their experiences playing Episodix changed these perceptions. For instance, the average participant's motivation to play video games increased by 40% after gameplay. Participants also indicated that the Episodix game seemed more engaging than the California Verbal Learning Test (CVLT) pen-and-paper test, which the game was based on. One potential reason for the game seeming more engaging than the CVLT may have been the comprehensive user-centered design process used in developing the game. A combination of validity testing, expert input, and user focus groups underpinned the development process. Through the design process, participants from both focus groups and the pilot experiment indicated a preference for a touch interface rather than a traditional keyboard and mouse setup. This finding was similar to that of the SASG game study. Technical developments were made to facilitate these preferences. The Episodix study [16] also reported important qualitative findings from user focus groups. The game was perceived as very useful by users, but they preferred it to be administered by a health

professional rather than self-administered, regardless of whether they were confident interacting with the game on their own. Participants agreed that if both instruments (the CVLT and the game) were demonstrated to perform the same cognitive assessment, they would prefer to play the game. However, participants preferred the digital intervention to be referred to as a test because they perceived the term *video game* to have negative and nonserious connotations.

Both the NL puzzle task and SMT studies [39,40] assessed user experience through the Perception of Game Training Questionnaire [50]. Participants rated the extent to which they found playing the games enjoyable, challenging, frustrating, and motivating. Both games were developed based on experimentally controlled versions of commercially available puzzle games. In addition, both games offered different difficulty levels to create an appropriate level of challenge for a broad range of users. In the NL puzzle task study, ratings of enjoyment (P=.43), challenge (P=.07), frustration (P=.06), and motivation (P=.67) for the game did not differ significantly between groups. The users generally rated the game experience positively in both the healthy aging group and the group with cognitive impairment. However, there was a slight, albeit statistically nonsignificant, increase in rating the game session as challenging and frustrating among older participants and/or those with impairment, particularly participants with PD and HD. According to the authors, further adapting the difficulty levels to a person's performance might partially reverse this trend. In the SMT study, there were significant differences between the 3 age groups regarding ratings of challenge (P<.001). Overall, young adults perceived the SMT as significantly less challenging than older adults (P=.02). There were also significant age group differences in average difficulty ratings for both the short version played by the young, older, and oldest adults (P<.001) and the long version (P<.001) played by the young and older adults. Despite this, there were no significant group differences regarding enjoyment, frustration, and motivation while playing the SMT task. One possible reason why challenge and difficulty levels varied across groups while enjoyment and motivation levels remained constant is that the SMT provided a total of 71 possible difficulty levels. This means that the game could be responsive to a user's gameplay and adjust the level of perceived challenge accordingly.

In the GBCA study [43], the user experience questionnaire included questions on game ease-of-use (not technically user experience), whether users felt the game stories were interesting and familiar, users' reactions to the interface design (typesetting, color, instruction, etc), and questions aimed at comparing the GBCA intervention with other cognitive assessment tools. The responses of the control group suggested that they were very satisfied with the game. By contrast, the average responses of participants with neurocognitive disorders were significantly lower than those of controls. Interestingly, lower scores given by the participants on the user experience questionnaire corresponded to a higher clinical dementia rating, older age, and a lower educational level. Higher levels of cognitive impairment appeared to adversely affect the participants' ability to use the tablet to complete the GBCA intervention, as indicated by the poor ratings given to questions regarding the design of the GBCA intervention. This finding raises questions about the functional usability of the game as well as the more subjective user experience. Furthermore, older age had a negative influence on the participants' satisfaction regarding the pictures, text, and story used in the game. This was somewhat surprising, given that the user interface of the GBCA intervention was intentionally designed to be acceptable for older users and included large pictures and buttons as well as spoken instructions so users could operate the app easily. The game could also be played by tapping buttons, drawing by dragging one's fingers over the touch screen, and speaking into a microphone (using low-cost speech recognition technology).

The Kitchen and Cooking study [41] also captured user experiences. The participants completed a questionnaire about the game experience at 2 points during the study. Specifically, satisfaction, interest, motivation (intrinsic and extrinsic), emotional experience of gameplay, and fatigue levels were assessed. The overall results of the self-report questionnaire showed that the participants were highly satisfied, interested, and motivated by the game experience. Intrinsic motivation was significantly higher than extrinsic motivation. Average user experience scores did not change between the 2 sessions, thus confirming the overall positive evaluation of the game after repeated gameplay. However, it is worth noting that scores did not trend upward after the second session regarding motivation, as observed in the Episodix study [16]. Of particular interest in this study is that participants with AD reported being significantly more satisfied with the game than participants with MCI (P=.04). This contrasts with the findings from the NL puzzle task, SMT, and GBCA studies, where the inverse trend appeared. Finally, the authors suggested that a critical factor in the success of the intervention was the presence of a clinician. The game was designed as a tool to help patients train outside clinical consultations. However, the periodic supervision of the clinician helped to explain the functioning of the game to the patients and their families, keep track of the evolution of the performance, adapt the intervention to the patients' changing needs, and maintain user motivation.

Discussion

Overview

The aim of this review was to investigate studies that evaluated the experiences of older people using GBCAs. Although the combined findings are from only 8 included papers, they establish promising preliminary user evaluation results for the use of GBCAs, albeit with some interesting implications for future design and development practices. Our review provides a much-needed synthesis of user evaluation findings from GBCAs, which have undergone psychometric validity testing. As such, we offer new insights regarding the relationship between the validity, usability, and user experience of GBCAs. This is particularly important with respect to the experiences of our target study cohort, older people (aged ≥50 years), whose input is greatly needed yet seldom included in GBCA design and development.

The first area of focus in this review was system usability. Usability scores were mostly positive across the studies

included. However, in some of the games presented, there were trends toward lower usability scores for participants with cognitive impairment. This was observed even when games were explicitly designed for older people and/or those with impairment, and tasks were simplistic and representative of basic daily activities, such as in the VST. In the VST, a game that has been validated in multiple contexts [15,47,48], no significant differences were found between the groups with subjective cognitive impairment and MCI in usability scores; however, participants who took longer to complete the test trials had lower self-reported usability. Usability challenges were further identified in the NL puzzle task and the SMT. Although both games had good usability scores on average, they both identified significant differences in usability ratings not only across cognitive health but also age range. On average, in both games, the older or more impaired a person was, the less usable they found the respective game system.

These collective findings on usability have some interesting implications. Traditionally, it has been assumed that system usability can be increased by improving the technical interactions a person has with a system, the intuitiveness of that system, and by reducing any bugs or errors that generate needless complexity within that system. For example, Joddrell and Astell [60] significantly improved the usability of solitaire for people with dementia (mean age 84.17, SD 8.35; range 66-102) by adding accessibility features such as additional card control options, clearer gameplay layout, and audio-visual feedback cues. However, this review highlights that while these technical and functional system improvements may be important, they are not necessarily sufficient to produce usable interventions for this target group of users. Individual variations in age, cognitive function, and gameplay performance may all impact functional usability, even when the system has been technically adapted to be suitable for older users and/or those with impairment.

The second focus area, regarding subjective user experience, identified the importance of perceived challenge in mediating gameplay experience across groups. In the GBCA study, the healthy control group was more satisfied with their experience of using the GBCA intervention than the group of participants with cognitive impairment, whereas the opposite trend appeared in the Kitchen and Cooking game. In the Kitchen and Cooking game, a simplistic interface based on a basic cooking task, game satisfaction was higher among the participants with AD than among participants with MCI. In the SMT task, there was a statistically significant difference in how challenging older and younger people found the game. However, levels of enjoyment and motivation remained the same. These contrasting results may be related to perceived gameplay challenges. For instance, the NL puzzle task, the SMT, and the GBCA were, on average, more complex than the Kitchen and Cooking game, with the NL puzzle task and SMT offering different levels of complexity for different users.

According to the broader literature on game design preferences, people want to be challenged to a level that will satisfy their need for competence [25]. Applying self-determination theory, it has been shown that a player will experience low competence if the challenges are too great (eg, game controls are overly complex or enemies are too numerous), and this will have a negative impact on a person's ability to enjoy the game [61]. If a game is too difficult, it can become frustrating and discouraging, reducing a user's motivation, engagement, and enjoyment. The optimal challenge (ie, the sweet spot) for any player is mediated by that individual's threshold for difficulty [62,63]. This may explain why basic gamified versions of simple tasks, such as in the Kitchen and Cooking game, were less motivating or enjoyable for younger participants and those without cognitive impairment. It may also explain why more "from scratch" serious games that offered more difficulty levels, such as the NL puzzle task and SMT, had constantly high enjoyment and motivation scores across the younger, older, and oldest groups of users.

Another noteworthy finding in this review relates to the role of a health professional during game-based assessment. Two studies identified the role of a health professional as essential to the success of their respective game interventions. In the Episodix game, although users demonstrated improved appreciation for the value of GBCAs after gameplay, this increased appreciation appeared to stem from the value of the game as a health tool. The presence of a clinician seemed to underpin this, as the game was perceived as very useful by users, but they preferred it to be administered by a health professional rather than self-administered. Likewise, in the Kitchen and Cooking study, the authors suggested a critical success factor for the intervention was the presence of a clinician. These findings raise questions about self-administration, which is seen as one of the most exciting (and valuable) applications of serious game technology [15]. Self-administration of GBCAs has been recently identified as a way to overcome some of the issues with formal assessment [15], such as significant test anxiety as well as self-stigma regarding low literacy or education levels when performing cognitive tests [9,10]. Self-administration may also empower people to take control of their own health earlier and more proactively than standard approaches. However, the findings of this review suggest that this autonomy and control may come with some unintended consequences, such as a lack of confidence in undertaking assessments without support, as well as a lower perceived value or legitimacy of the assessment. This is important to recognize as a potential downside for self-administrated GBCAs.

The Objectives of GBCAs and Subsequent Tensions With Usability and User Experience

One approach often taken when designing and developing cognitive games for older people and/or individuals with cognitive impairment is to make the game easy. This appears to have been the design strategy in games such as SASG, VST, and Kitchen and Cooking, where the games were based on simple daily living tasks, and the design and development of the games were tailored to people with cognitive decline. These games were quite successful at engaging older people with significant cognitive impairment. However, given that the objective of a GBCA is to assess maximal cognitive capacity, adapting the floor and ceiling to make games easier may not always be desirable. This is because the reason for adding complexity to a GBCA, besides increasing user engagement, is to improve the sensitivity of a game to detect cognitive

functioning more accurately. In other words, a game that is too simple or too domain specific may not be relevant for healthier older adults or those with milder or more complex forms of cognitive impairment, even if it is more appropriate for people with more significant cognitive decline. For instance, the basic requirement of shopping for groceries in the VST may be suitable for people with moderate neurocognitive disorders; however, it may not detect subtle impairments or small cognitive changes over time in healthier participants. More simplistic games are also unlikely to be very enjoyable or challenging (ie, satisfying a need for competence) for many people without neurocognitive disorders (as was observed in some of the studies included). This reduces their viability as a scalable screening tool. By adding more challenge and complexity, it becomes feasible to engage a broader user group and assess multiple cognitive domains. This, of course, comes at the risk of marginalizing the most vulnerable and arguably important cohort: those with significant impairments. It is also important to note that people with more significant neurocognitive disorders are unlikely to be the intended target of most GBCAs, or even traditional cognitive screening. This is a tension that has been seldom discussed or investigated in the growing body of literature on GBCAs.

Overall, the goals of usability and user experience—foundational to human-centered design approaches—and the intention of GBCAs and cognitive testing, in general, reveal a potentially problematic misalignment that warrants further discussion. For instance, according to ISO, the basic requirement of usability is that a product can be used (by target users) to achieve specific goals with effectiveness, efficiency (ie, in minimum time and with minimum errors), and satisfaction in a specified context [27]. However, is it reasonable, desirable, or even possible to meet this standard when developing a GBCA? If the primary goal of a cognitive test is the detection of cognitive deficits, the implication is that people with cognitive impairment will likely (1) fail to achieve certain tasks, (2) take longer to complete objectives, and (3) make more errors than cognitively healthy people.

In fact, reliable detection of these "failures" is essential to ensure a valid and clinically meaningful test of cognitive performance. Thus, intentionally producing user failure states is a central design tenet when developing GBCAs, and this, as we have identified through this review, may cause reductions in usability and subjective user experiences.

However, while this may risk departing somewhat from the principles of user-centered design, it is important to recognize that the "serious" objective of a GBCA is not necessarily to maximize unconstrained usability and user experience; rather, it is to produce a cognitive assessment that is more motivating and engaging than a traditional task. As traditional tasks are sometimes reported to be tedious, boring, anxiety provoking, and stigmatizing, the objective of a GBCA is to improve the subjective user experience relative to traditional approaches while maintaining functional usability. This implies that a GBCA may not necessarily need to be maximally fun but simply "fun enough" while being motivating, engaging, and technically usable. Furthermore, what "usable" means in this context is potentially hard to reconcile with the ISO aim of effectiveness, efficiency, and satisfaction. For instance, if an intervention is too easy to use, can it adequately produce the failure states that are the primary objective of a GBCA?

These open questions become even more interesting when we consider that the intended application of GBCAs, at least in the near future, is likely to be a relatively short (eg, 10-20 min) user experience (ie, replacing a cognitive screen), which is only "played" by users sporadically. The implication is that traditional user-centered game design that focuses on intrinsically motivating features, such as narrative and social connectedness, may not be feasible or desirable. This, in many ways, is misaligned with the overarching goals of human-centered design, yet it is arguably more consistent with the preferences of older people taking a cognitive test. In fact, this was what we reported in a recent qualitative study investigating the GBCA preferences of older people in prison [25]. We found that GBCAs with numerous immersive game features risked being perceived as too childish for the serious context of a cognitive test. This was also likely the case in the Episodix study sample, where participants preferred the digital intervention to be referred to as a test because they perceived the term game to be nonserious [16]. However, we argue that these tensions do not reduce the value of incorporating usability and user experience principles into the development of GBCAs; rather, they simply reframe what the feasible intention of a GBCA ought to be in the context of user experience and usability. Perhaps "good enough" usability and user experience are good enough?

Our conclusion is that there is an inherent tension between usability, user experience, and GBCAs that (1) in the meantime should be carefully considered when designing and developing GBCAs, especially for older people; and (2) requires additional research to further explore and potentially resolve. We offer some key lessons in the Implications for Practice subsection. Regarding future research, we suggest an urgent need for further mixed methods research that incorporates the qualitative preferences of older people using GBCAs with rigorous validity testing. In addition, there is a need to explore what "good enough" usability and user experience may mean in this context and how these concepts can be tested and incorporated into game design, development, and improvement.

Limitations

This review has some limitations. Many of the participant samples were small, and the studies involved slightly different target user groups. Most studies focused on user evaluation as a secondary outcome, with psychometric validity testing being the primary aim in most papers. All the games included in this review were distinct from one another regarding design and development processes and, as a result, the end products. Combined with the disparities in sampled participants, this heterogeneity makes it inappropriate to make specific recommendations regarding which precise techniques work for whom in what contexts. This is further complicated by the fact that most of the games did not seem to be publicly available, creating uncertainty about how well developed and sophisticated the games actually are in practice. This lack of access to the games, beyond what was described and visualized in the primary research papers, also inhibited a more comprehensive review

of specific design choices based on a more technical analysis of mechanics and processes. However, despite these limitations, we were still able to interpret the findings in the context of the broader literature on serious games and provide general lessons learned for designing and developing GBCAs.

In addition, there were also some limitations related to the methods applied for user evaluation. Most user evaluation data were collected via self-report and are thus exposed to the well-established biases associated with this collection method. Furthermore, although the SUS is well validated, it is short and generic. Thus, it does not present a comprehensive assessment of game usability, and its validity for people with neurocognitive disorders has not been established. Other reported usability and user experience findings came from disparate tools, some of which were customized from other scales or created based on theory. This created additional barriers when attempting to synthesize the findings quantitatively and prevented a meta-analysis. Some of these limitations were evident in the quality appraisal, in which a case-control checklist was used to assess the risk of bias. This basic checklist was deemed appropriate because most of the study papers included games that were still in the pilot stage of development and, thus, not ready for more sophisticated diagnostic appraisal. Regardless, it is hoped that a more sophisticated and suitable appraisal tool can be used in future research to adequately assess the quality of papers investigating the psychometric validity and user experiences of GBCAs.

Implications for Practice

Overview

This systematic review aimed to synthesize the user evaluation data from psychometrically validated GBCAs played by older people. As part of this process, we have identified key lessons for developing potentially transformative assessments using gamified technology. These preliminary key lessons have been developed based on our systematic review of the included studies, our own primary research experiences (eg, Mantell et al [25]), and a broader synthesis of relevant theory and literature (eg, self-determination theory). Given that this is still a relatively new area of scientific inquiry, we hope that these lessons can serve as guidance for clinicians, researchers, and game developers who find themselves navigating the complexity of creating GBCAs that are both clinically effective and offer "good enough" user experiences and usability. More broadly, we hope this review can support and inform more evidence-based and rigorous design, development, and evaluation of GBCAs for older users in the future.

Validity Is Very Necessary but Not Sufficient

A game may function as an assessment tool in theory, but if it is not usable or engaging, it is unlikely to work in practice. Input from both users and game designers, at the outset and throughout the design process, is the best way to ensure a game is suitable. This is usually best done alongside an expert reference group working to ensure the game has psychometric validity [13]. The more the target users, developers, and cognitive experts collaborate, the more likely the game will succeed. Furthermore, researchers should always plan to evaluate game usability, as well as user experiences and preferences, to formally investigate the success of their game (and identify any scope for improvement).

Clarify the Intended User

There is a complex relationship between cognitive decline, usability, and user experience as people age. Many older people with cognitive impairment will respond better to simple gamification of realistic tasks. More complex serious games risk becoming less appealing as people become older or more impaired, and this will impact usability and user experience. However, the more rudimentary the game-based task, the less likely it is to engage younger adults or those with better cognitive function. To proactively address this tension, developers should begin with a critical question: who is this intervention for, and what exactly is the game intended to assess? For instance, "good enough" usability and user experience are probably good enough for a short and sporadic cognitive screener targeting older adults at risk of impairment. However, this may not be the case for a more expansive game trying to also engage younger cohorts and track more subtle cognitive changes over time.

Create Games That Align With the Unique Preferences and Needs of Older People

Older people appear to prefer games that avoid childlike features, are intellectually focused (eg, puzzles), and/or are based on the replication of real-life tasks or challenges. Avoiding fantasy, violent content, and multiplayer interaction is recommended. Large digital touchscreen devices, such as tablets, also seem to be more usable and intuitive for older people than smaller devices, mouses, or virtual reality [16,38,64]. However, tablets can also create ergonomic difficulties for older people who may be frail or have specific neurological conditions (eg, difficulty holding the device steadily, dyspraxia, or visuospatial impairment), and these factors need to be accounted for [18].

Providing Each User With Their Optimal Challenge Is Key

Tailoring the level of difficulty (known as difficulty balancing) to an individual's capacity should be attempted wherever possible in the design of GBCAs. It has been shown that this personalization does not need to be highly sophisticated to be useful in increasing user experience [37,39]. Introducing various levels or randomly generating different design elements or challenges per round can also make it possible to detect more subtle impairments and reduce learning effects [37]. In addition, it can also alleviate some of the tension between providing games that are suitable for older people or those with more impairment and maintaining sensitivity for more subtle cognitive decline, as more levels mean a lower floor and higher ceiling.

Abstract

Background: With social progress, social stress (SS) has become a key factor affecting health. Unhealthy lifestyles may exacerbate these effects. However, the relationship between SS, lifestyle, and older adults' mortality rate still needs to be studied.

Objective: This study aimed to explore the relationship between SS and all-cause mortality in Chinese older adults, as well as the influence of healthy lifestyle factors.

Methods: Three groups of SS were defined through latent class analysis: low, medium, and high. We created a healthy lifestyle index based on smoking, alcohol consumption, physical activity, and diet. Multivariable Cox proportional hazards models, interaction analyses, and mediation analyses were conducted.

Results: The Chinese Longitudinal Healthy Longevity Survey (CLHLS) datasets included participants from 806 cities and counties across 23 provinces in China from 1998 to 2018. In this study, participants were recruited from 4 waves of the CLHLS (2005, 2008, 2011, and 2014). Finally, 19,236 participants were included in this study, of which 6891 (35.8%) had low SS, 11,662 (60.6%) had medium SS, and 683 (3.6%) had high SS. In the fully adjusted model, the hazard ratio (HR) for medium SS was 1.16 (95% CI 1.11 - 1.20; *P*<.001), and for high SS, it was 1.28 (95% CI 1.18 - 1.40; *P*<.001) compared to the low SS group. For individuals aged ≥80 years, the medium SS group had a 28% (HR 1.28, 95% CI 1.22 - 1.34; *P*<.001) increased mortality risk, and the high SS group had a 38% (HR 1.38, 95%CI 1.26 - 1.52; *P*<.001) increased risk compared to the low SS group. Approximately 7% of the association between SS and mortality was mediated through the healthy lifestyle. Under different SS, the lower the healthy lifestyle score, the higher the risk of mortality.

Conclusions: SS was an independent predictor of all-cause mortality in Chinese older adults. The healthy lifestyle mediated this effect to some extent. Unhealthy lifestyle behaviors were associated with a higher risk of mortality at all SS levels.

KEYWORDS

social stress; healthy lifestyle; mortality; older adults; cohort study

Introduction

As social progress advances, increasing attention has been given to the impact of chronic social stress (SS) on human health. SS is a complex and multifaceted construct, typically encompassing 3 key areas, such as interpersonal relationships, economic conditions, and the living environment. Interpersonal stress arises from demands and expectations within family, friendships, and work relationships [1]. Economic stress is primarily linked to concerns over income or job stability [2] while environmental stress involves factors, such as housing stress and access to social services [3]. All of these factors can contribute to an individual's overall level of SS. Clinical and biological studies have demonstrated that long-term exposure to stress can disrupt the normal functioning of biological systems, leading to negative health outcomes, such as cardiovascular disease [4], gastrointestinal disorders [5], and immune dysfunction [6]. In addition, unhealthy lifestyle behaviors, such as poor diet, physical inactivity, and smoking, are well-documented risk

factors for a range of chronic diseases and premature mortality [7], and may further compound the adverse effects of SS.

China is undergoing a significant demographic shift, with a rapidly aging population. As such, the health and well-being of older adults have become key areas of focus. While stress affects individuals at all stages of life, its impact on older adults warrants particular attention. Studies have shown that stress may be linked to poorer health in older adults [8-10]. However, more research is needed to understand how SS affects the health of older adults and the impact of lifestyle.

This study aimed to investigate the impact of different levels of SS on mortality among Chinese adults older than 65 years, using data from the Chinese Longitudinal Healthy Longevity Survey (CLHLS). In addition, the study investigated the possible impact of a healthy lifestyle on the relationship between SS and all-cause mortality.

Methods

Study Population

The data for this study were drawn from the Chinese Longitudinal Healthy Longevity Survey (CLHLS), a prospective cohort study described in detail in previous publications [11,12]. In brief, the CLHLS was based on a dynamic, multistage stratified sampling design, which includes participants from 806 cities and counties across 23 provinces in China from 1998 to 2018. The survey covers 85% of the Chinese population, with a focus on individuals aged 65 years and older [13]. Data collected include information on demographic characteristics, socioeconomic status, lifestyle factors, and health-related variables. For this analysis, 27,585 participants were recruited from 4 waves of the CLHLS (2005, 2008, 2011, and 2014). During the follow-up surveys, the survival status of the participants was ascertained as surviving, dead, or lost to follow-up. Participants were excluded if they met any of the following criteria: (1) lost to follow-up or dead before (n=5285), (2) age younger than 65 years at baseline (n=201), and (3) missing baseline information (n=2863). After applying these exclusions, the final sample consisted of 19,236 participants.

Assessment of SS

Existing research primarily examines the impact of SS on health from 3 aspects, namely, interpersonal relationships, economic conditions, and housing conditions [14-16]. Accordingly, our study assessed SS among the older adult population in the CLHLS based on these 3 dimensions. Based on the investigation of relationships with marriage, the health of children, and social support, these questions further transformed into 3 questions, such as “Do you live with your spouse?,” “Are your children still alive?,” and “Do you have someone with whom you can talk, confide in, or seek help when needed?” Economic status was measured by the question, “Is all of the financial support sufficient to pay for daily expenses?” Housing stress was evaluated using the question, “How many people are living with you?” Given the living arrangements typical for older adults in China, those living alone or with more than 5 people were categorized as experiencing housing stress (Table S1 in Multimedia Appendix 1).

Assessment of Healthy Lifestyle Score

A healthy lifestyle was defined by 4 factors, such as smoking, alcohol consumption, physical activity, and diet. Participants who had never smoked or had quit smoking for at least 30 years were assigned 1 point [17]. Men who consume less than 62 g of alcohol per day or women who consume less than 41 g per day were assigned 1 point [18]. Physical activities included regular exercise (both aerobic and anaerobic), housework, tasks, outdoor activities, gardening, pet care, reading, playing cards or mahjong, watching television or listening to the radio, and attending social events. The frequency of “almost every day” was scored as 2, “occasionally” was scored as 1, and “rarely or never” was scored as 0. A total physical activity score was calculated by summing the points across these categories and then standardized to a range of 0-1. A score below 0.6 was assigned 0 points while a score of 0.6 or above was assigned 1 point (Table S2 in Multimedia Appendix 1). The dietary score was determined using a standardized food frequency questionnaire that includes fresh vegetables, fresh fruits, legumes, meat, eggs, fish and seafood, salty vegetables, tea, and garlic. Similar to physical activity, the score for each food group was based on frequency of consumption, and the total dietary score is calculated accordingly (Table S3 in Multimedia Appendix 1). The final lifestyle score ranged from 0 to 4, with higher scores indicating a healthier lifestyle [19].

Outcome

Death was confirmed either by official death certificates or through information provided by the participant’s next of kin, local physician, or resident physician. The follow-up period was defined as the time from study enrollment to the date of death or the last follow-up, whichever came first. Loss to follow-up was defined as the inability to contact the participant after at least 3 documented attempts.

Covariates

Several variables were considered as potential confounding factors. The first set included demographic variables, namely, age (y), sex (male or female), residence (urban or rural), education, and occupation prior to retirement. Considering that the participants included in this study were 65 years old and above, 0 years of education was defined as low, less than 5 years of education was defined as medium, and 5 years of education or more was defined as high. Occupations before retirement were divided into farming, employed, and unemployed. The second set included the history of chronic diseases, such as hypertension (yes or no), diabetes (yes or no), heart disease (yes or no), stroke and cerebrovascular disease (yes or no), and cancer (yes or no). The history of chronic diseases was measured with the following question: “Have you been diagnosed by a doctor with the conditions listed below?”

Statistical Analysis Methods of the Results

Continuous variables were summarized as means and SDs while categorical variables were presented as counts (N) and percentages (%). Differences between groups were assessed using analysis of variance for continuous variables and the chi-square test for categorical variables. Cox proportional hazard regression models were used to estimate the hazard ratios (HRs)

and 95% CI for mortality associated with SS and healthy lifestyle scores. The proportional hazards assumption was tested using Schoenfeld residuals. Model 1 was unadjusted; Model 2 adjusted for age and sex; Model 3 further included education level, occupation, and residence; and Model 4 additionally adjusted for healthy lifestyle factors. Mediation analysis was used to further explore the role of healthy lifestyle in the relationship between SS and all-cause mortality. In addition, the product term of SS and healthy lifestyle score was added to the model to examine their multiplicative interaction. The relative excess risk due to interaction and its corresponding 95% CI were used to assess the interaction on the additive scale. This was calculated using the coefficients and SEs of the product term, SS, and healthy lifestyle score, along with the covariance matrix.

Latent class analysis (LCA) was used to classify participants into distinct SS groups. Convergence was defined as a maximum absolute deviation of 0.000001 between parameter estimates across successive iterations. Iterations terminated when this deviation threshold was reached. Model selection was guided by criteria, including Akaike Information Criterion, Bayesian Information Criterion, likelihood ratio statistic (G^2), and entropy value. Entropy, ranging from 0 to 1, assesses the accuracy of classification in LCA, with higher values indicating better model classification accuracy. In this study, after convergence failed for the 6-class model, 5 latent class groups were selected for comparison, with optimal model performance observed at 3 latent classes based on the highest entropy values (Tables S4-S6 in Multimedia Appendix 1).

Furthermore, when we analyze the impact of a healthy lifestyle on mortality under different SS conditions, the small number of healthy lifestyle groups in the high SS group may affect the results. Therefore, we combined the medium SS group and the high SS group into the medium-high SS group for analysis. We conducted a subgroup analysis stratified by age, sex, education, residence, and occupation to present the differences. We performed several sensitivity analyses to test the robustness of our results: (1) Excluded deaths that occurred within the first 2 years of follow-up. (2) Excluded the mediating effect of each lifestyle factor on the relationship between SS and all-cause mortality. (3) The results were evaluated again by weighting the lifestyle scores. (4) Due to the low proportion of participants with lifestyle scores of 2 and 3, they were combined into 1 group for analysis.

All analyses were based on R version 4.3.2 (R Foundation for Statistical Computing). All statistical tests were 2-sided, with $P<.05$ considered to be indicative of statistical significance.

Ethical Considerations

This study was approved by the Ethics Committee of Peking University (IRB00001052 −13074), and informed consent was obtained from all participants. All data were anonymized and deidentified to protect participant privacy. Participants provided written consent for the publication of their anonymized data and quotes in this study.

Results

Baseline Characteristics

A total of 19,236 Chinese adults aged 65 years and older were included in this prospective cohort study (Figure 1). Among them, 6891 (35.8%) people had low SS, 11,662 (60.6%) people had medium SS, and 683 (3.6%) people had high SS. The overall mean age of the participants was 88 (SD 12) years. Overall, females, rural residents, medium education, and agriculture make up a larger proportion of the total population. The high SS group exhibited a higher proportion of individuals experiencing several adverse conditions, including the loss of children, lack of social support, living without a spouse, insufficient financial resources to cover daily expenses, and housing stress. Overall, 6827 (35.5%) participants had a healthy lifestyle score of 0, 7017 (36.5%) participants scored 1, 2633 (13.7%) participants scored 2, and 2759 (14.3%) participants scored ≥3. Chronic disease conditions and other details can be seen in Table 1.

[a]Education: low (0 y), medium (<5 y), high (≥5 y).

[b]Healthy lifestyle was defined by 4 factors: smoking, alcohol consumption, physical activity, and diet. Healthy lifestyle score ranges from 0 to 4, with higher scores indicating a healthier lifestyle.

Association of SS and All-Cause Mortality

In the unadjusted analysis (Model 1), compared with the low SS group, the results showed the HRs of the medium and high SS groups were 2.05 (95% CI 1.98 - 2.13) and 2.47 (95% CI 2.26 - 2.69). After adjusting for age and sex (Model 2), the HRs of the medium and high SS groups were 1.15 (95% CI 1.11 - 1.20) and 1.37 (95% CI 1.26 - 1.50). In Model 3, which further adjusted for local education, occupation, and healthy lifestyle score based on Model 2, the HRs of the medium and high SS groups were 1.15 (95% CI 1.11 - 1.20) and 1.28 (95% CI 1.17 - 1.39). In the fully adjusted Model 4, the mortality risk for medium SS was 1.16 (95% CI 1.11 - 1.20), and for high

SS, it was 1.28 (95% CI 1.18 - 1.40) compared to the low SS groups (Table 2).

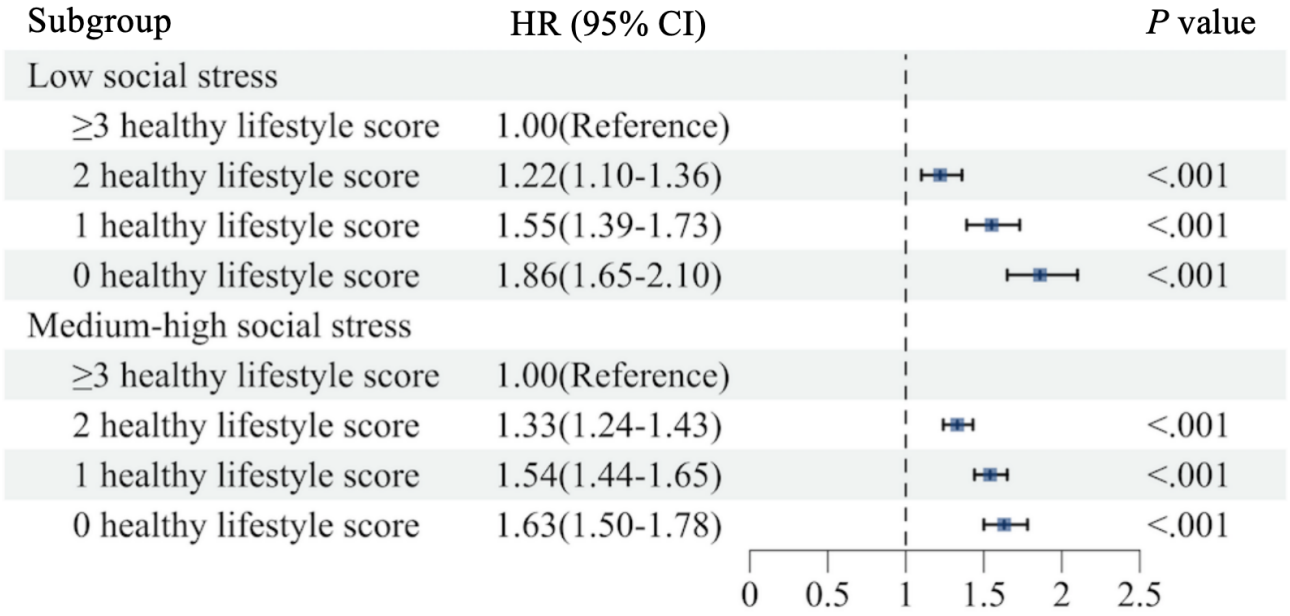
Impact of a Healthy Lifestyle on All-Cause Mortality Across Different SS Groups

The lower the healthy lifestyle score, the higher the risk of death compared with a healthy lifestyle score ≥3 (Table S7 in Multimedia Appendix 1). For the low SS group, individuals with a higher healthy lifestyle score had a lower mortality risk. Specifically, compared to those with a healthy lifestyle score of 3 or more, individuals with a score of 2 had a 22% increased risk of mortality (HR 1.22, 95% CI: 1.10 - 1.36), those with the score of 1 had a 55% increased risk (HR 1.55, 95% CI 1.39 - 1.73), and those with the score of 0 had an 86% increased risk (HR 1.86, 95% CI 1.65 - 2.10). Further combining the medium and high SS groups, the results found that individuals with a score of 2 had a 33% higher mortality risk (HR 1.33, 95% CI 1.24 - 1.43) compared to those with a score of 3 or more. The score of 1 was associated with a 54% higher risk (HR 1.54, 95% CI 1.44 - 1.65), and the score of 0 was associated with a 63% higher risk (HR 1.63, 95% CI 1.50 - 1.78) (Figure 2).

Figure 2. Impact of a healthy lifestyle on all-cause mortality across different social stress groups. All covariates were adjusted. HR: hazard ratio.



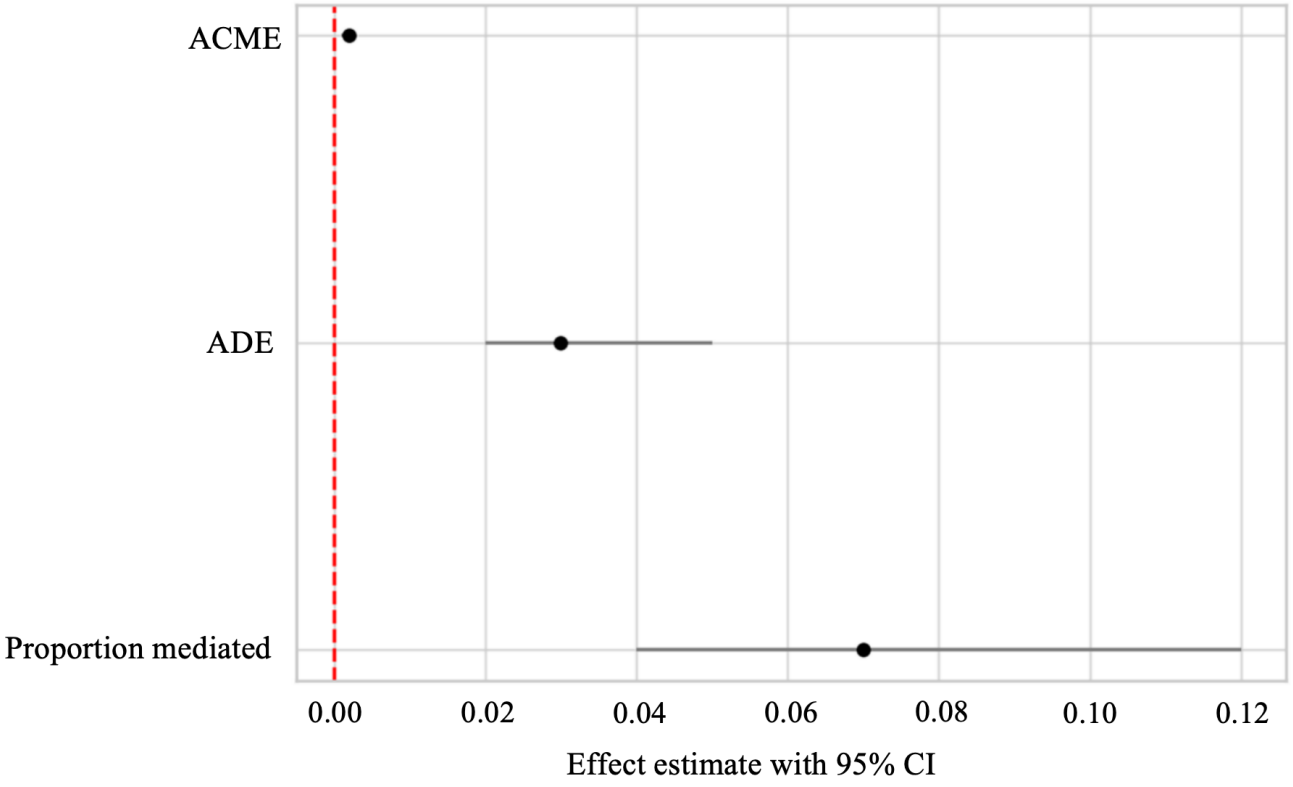
Mediation and Interaction Analysis of a Healthy Lifestyle on Associations of SS With All-Cause Mortality

The proportion of the total effect of SS on all-cause mortality that is mediated through a healthy lifestyle was 0.07 (95% CI 0.04-0.12), with a *P* value <.001. This suggests that approximately 7% of the association between SS and mortality is explained by the mediation effect of a healthy lifestyle. The average direct effect of SS on all-cause mortality, independent of the mediation through a healthy lifestyle, was 0.03 (95% CI 0.02-0.05), with a *P* value <.001. The average causal mediation effect was 0.002 (95% CI 0.001-0.002), with a *P* value <.001. These findings demonstrate that a healthy lifestyle partially mediates the relationship between SS and all-cause mortality (Figure 3).

After multiplicative interaction, the interaction term exponentiated coefficient (exp [coef]) is 0.941, and the *P* value

was less than .001, indicating that there was a significant multiplicative interaction between social pressure and a healthy lifestyle. The additive interaction results showed that the relative excess risk due to interaction was measured to be 0.127 (95% CI 0.013 - 0.240), indicating the existence of a positive additive interaction. The attributable proportion due to interaction was found to be 0.071 (95% CI 0.017 - 0.124), indicating that 7.1% of the combined mortality risk caused by social pressure and unhealthy lifestyle can be attributed to the synergistic effect of both factors. The Synergy Index was calculated to be 1.189 (95% CI 1.060 - 1.334), indicating that when SS coexists with unhealthy lifestyles, the risk of death is 1.189 times higher than the sum of their individual effects.

Figure 3. The mediating effect of a healthy lifestyle in the relationship between social stress and all-cause mortality. ACME: average causal mediation effects; ADE: average direct effects.



Stratified and Sensitivity Analyses

We analyzed the effects of SS and a healthy lifestyle on the oldest- and nonoldest-old. The results showed that there was a significant association between SS and mortality risk in both the ≥80 years and <80 years age groups (Table S8 in Multimedia Appendix 1). In the older adults and nonolder adults groups, regardless of stress level, the mortality risk (HR) increased significantly as the healthy lifestyle score decreased (from ≥3 points to 0 points) (Figure S1 and Table S9 in Multimedia Appendix 1). In the older adults and nonolder adults groups, healthy lifestyle partially mediated the relationship between SS and mortality risk (Table S10 in Multimedia Appendix 1). The associations of SS, healthy lifestyle, and all-cause mortality were generally similar across sex (Table S11 in Multimedia Appendix 1), residence (Table S12 in Multimedia Appendix 1), occupation (Table S13 in Multimedia Appendix 1), and education (Table S14 in Multimedia Appendix 1). The associations of SS, healthy lifestyle, and all-cause mortality did not change appreciably when we excluded participants who died within 1 or 2 years of follow-up (Table S15 in Multimedia Appendix 1). The mediating effects of different components of a healthy lifestyle (smoking, alcohol consumption, physical activity, and diet scores) on the relationship between SS and mortality were further analyzed (Table S16 in Multimedia Appendix 1). Association of SS with all-cause mortality after adjustment for weighted lifestyle score and other covariates (Table S17 in Multimedia Appendix 1). Since the population with lifestyle score=2 and lifestyle score=3 each accounted for 1/3 of the other population (lifestyle score=0 or 1), we combined the population with score 2 and score 3 for sensitivity analysis, and the results remained robust (Table S18 in Multimedia Appendix 1).

Discussion

Principal Findings

In this large prospective cohort study, we investigated the impact of SS and a healthy lifestyle on mortality among older adults in China. Our findings showed that both medium and high levels of SS were associated with increased mortality risks, with HRs of 1.16 and 1.28, respectively, compared to the low SS group after full adjustment for covariates. For individuals aged <80 years and ≥80 years, the HRs of the high SS group were 2.09 and 1.38. SS has a greater impact on the mortality of older adults younger than 80 years. These results underscore the significant impact of SS on health outcomes in older adults. Approximately 7% of the association between SS and mortality was mediated through the healthy lifestyle. Under different SS, the lower the healthy lifestyle score, the higher the risk of mortality. These

results provide valuable insights into the complex interplay between SS and health behaviors in shaping mortality risks among older adults in China.

Chronic SS has been shown to induce a range of physiological and behavioral changes that contribute to the development or progression of various health conditions [20]. Previous studies have demonstrated that prolonged exposure to stress elevates plasma cortisol levels, which may lead to memory impairment [21]. Mild stress could help improve cognitive function, but if the intensity of stress exceeded a predetermined threshold (which is different for each person), it could lead to cognitive impairment [22]. Stress could affect the function of the immune system by regulating the processes of the central nervous system and the neuroendocrine system [23]. In addition, stress could affect the occurrence of cardiovascular disease, gastrointestinal disease, endocrine disease, and other diseases [24-26]. A study from China explored the relationship between SS and health inequality and confirmed that SS has a greater impact on people with low economic status [14]. However, most existing studies focus on the impact of SS on psychological or psychiatric diseases. In addition, there is currently a lack of research on the impact of SS on the survival of Chinese older adults and the role of lifestyle in this association. With the aging trend in China, it is necessary to explore the relationship between SS and the health of older adults [27,28]. In our study, we found that compared with low SS, moderate and high SS increased the risk of death in Chinese people aged 65 years and more than 65 years to varying degrees, and lifestyle played a partial mediating role. This study provides causal support for the relationship between SS and the health of older adults through prospective analysis.

Although stress and its effects occur at all stages of an individual's life, with the rapid development of China's aging population, the social pressure faced by older adults has increased, mainly including pressure from interpersonal relationships, the economy, and the environment [29,30]. These components are interrelated and should be examined collectively in relation to health outcomes in older adults. Our study divided these 3 variables into 3 levels, such as low, medium, and high, based on LCA analysis. The results showed that among adults aged 65 years and older, compared with low SS, medium SS increased the risk of death by 16%, and high SS increased the risk of death by 28%. Approximately 7% of the association between SS and mortality is explained by the mediation effect of a healthy lifestyle. This indicates that SS directly influences mortality risk among older adults, and although a healthy lifestyle partially mediates this relationship, the effect size is small. We speculated that there may be several reasons. First, for older adults, the impact of SS may have already had a cumulative effect on their physical health earlier in life, and adopting a healthy lifestyle may not be sufficient to fully offset this long-term negative impact. Second, with age, declining physical functioning, accumulated chronic diseases, and a weakened immune system may reduce older adults' ability to benefit from a healthy lifestyle. Third, social pressure is a complex stressor that may affect the health of older adults' pathways, such as mental well-being, immune function, quality of life, and other mechanisms. Older adults may face higher levels of loneliness and reduced social support, and a healthy lifestyle may not sufficiently mitigate the physiological and psychological effects of these pressures.

Furthermore, participants aged ≥80 years were analyzed separately from younger older adults. We found that SS had a greater impact on mortality risk among older adults aged less than 80 years. Compared with the low SS group, mortality risk increased by 35% and 109% in the medium and high SS groups, respectively. Among adults aged 80 years and older than 80 years, the risk of death increased by 28% and 38% in the medium and high SS groups, respectively, compared to the low SS group. This suggests that SS may pose a greater threat to the survival of younger-old adults. Several factors may help explain this phenomenon. First, younger-old adults may be in a critical stage of lifestyle change, such as facing adaptation after retirement, changes in social roles, etc. Stress may accelerate the occurrence or aggravation of cardiovascular diseases, diabetes, and other chronic diseases, potentially leading to premature death [31]. Second, younger-older adults may not fully cope with SS, resulting in a surge in emotions, such as anxiety and depression [32]. Third, younger-older adults may experience greater economic pressure, including ongoing family expenses and housing challenges [33]. Fourth, in response to a rapidly changing social environment, younger-old adults may adopt unhealthy coping strategies, such as smoking or alcohol consumption, which can exacerbate health risks [34]. Therefore, our findings suggest that age-specific interventions may be necessary to reduce the impact of SS on the health and survival of older adults. This study investigated the interaction between SS and healthy lifestyle on all-cause mortality, using both multiplicative and additive interaction models. The findings revealed a statistically significant interaction effect, suggesting that the relationship between SS and mortality is modified by a healthy lifestyle. The additive interaction highlights the importance of addressing both SS and unhealthy lifestyles simultaneously. Interventions targeting stress reduction alongside lifestyle promotion could yield greater mortality benefits than addressing either factor in isolation.

Studies have shown that SS affects health through a variety of biological pathways. For example, long-term SS may increase cortisol levels in the body, which may lead to decreased immune function and enhanced inflammatory response, thereby increasing the risk of illness or death [35]. Our study suggests that reducing SS among older adults may help improve their quality of life. Moreover, our study found that social pressure had a greater impact on mortality risk among males, as well as among older adults who lived in urban areas, had never been employed, and had received more than 5 years of education. These findings offer valuable insights for future research on SS among older adults.

Our study has several major strengths, including a large sample size and a prospective cohort study. To our knowledge, no previous study has provided a detailed analysis of SS and mortality among the older adult population in China. Nevertheless, our study also has some limitations. First, data related to SS and data related to healthy lifestyles were based on self-reports, which, despite strict collection criteria, are still prone to measurement errors. Second, cause-of-death data were

not comprehensively recorded, limiting our ability to assess the impact of SS on cause-specific mortality among older adults. Third, residual confounding could not be fully eliminated due to limited covariates, such as the absence of genetic data and information on other health conditions. Fourth, this study only focuses on the social pressure composed of interpersonal relationships, economic status, and living environment and may not have considered other related factors. Fifth, although our lifestyle score included key behavioral factors, such as smoking, diet, physical activity, and alcohol consumption, other potentially important components, such as sleep duration and quality, perceived stress, and sedentary behavior, were not included due to data limitations. Sixth, we did not consider the potential changes in lifestyle factors during this period, which may affect the observed results. Therefore, more relevant studies are needed to provide evidence for the present findings.

Conclusions

The results showed that SS was an important risk factor for all-cause mortality in the Chinese older adults. This association remained strong even after adjusting for various sociodemographic and health-related factors, highlighting the importance of SS as a determinant of mortality risk in the Chinese older adults. A healthy lifestyle only partially mediated the relationship between SS and survival among older adults. However, an unhealthy lifestyle was associated with an increased risk of mortality, regardless of SS level.

Acknowledgments

The authors express their gratitude to the participants and staff involved in data collection and management in the Chinese Longitudinal Healthy Longevity Study. This study was supported by the National Natural Science Foundation of China (82425052) and the Postdoctoral Fellowship Program of CPSF (GZC20231052).

Data Availability

Data are available from the Chinese Longitudinal Healthy Longevity Study upon request [36]. Deidentified datasets will be provided following approval, with no restrictions on noncommercial use.

Authors' Contributions

XS, YL, and CM collected the data. JY and JH analyzed and interpreted the data. JY and JH wrote the manuscript. QH, JG, DL, and ZL checked the data and results. CM and XS were co-senior authors for this article.

Abstract

Background: In recent decades, the global life expectancy has risen notably to approximately 73.5 years worldwide, coinciding with a rapid growth in the older adult population, which presents a significant public health challenge in promoting healthy aging and longevity.

Objective: This study aimed to prospectively investigate the link between edentulousness and the likelihood of reaching centenarian status among individuals aged 80 years and older.

Methods: Data from the Chinese Longitudinal Healthy Longevity Survey were analyzed. Logistic regression models were used to assess the relationship between edentulousness and the likelihood of becoming a centenarian. Demographic characteristics, lifestyle habits, and disease histories were adjusted as confounding factors. Several sensitivity analyses, including propensity score matching and 2-year lag analyses, were conducted to further assess the association between edentulousness and the likelihood of becoming a centenarian. The correlation between the number of natural teeth as a continuous variable and the likelihood of becoming a centenarian was evaluated as well.

Results: The study included 4239 participants aged 80-100 years. After adjusting for all covariates, the likelihood for becoming a centenarian increased in the nonedentulous group compared to the edentulous group (odds ratio [OR] 1.384, 95% CI 1.093 - 1.751). The relationship persisted after propensity score matching analysis (OR 1.272, 95% CI 1.037 - 1.561). The association remained statistically significant after excluding participants with a follow-up duration of less than 2 years (OR 1.522, 95% CI 1.083 - 2.140; *P*=.02). Furthermore, a significant positive association between the number of natural teeth and the likelihood of becoming a centenarian was found after adjusting for all covariates (OR 1.022, 95% CI 1.002 - 1.042; *P*=.03), which aligned with the main results of the study.

Conclusions: The findings revealed that the presence of natural teeth was linked to an increased probability of becoming a centenarian, underscoring the importance of maintaining oral health even in advanced age.

Introduction

Over the past few decades, the global life expectancy at birth has significantly risen to approximately 73.5 years worldwide and 77.6 years in mainland China [1,2]. Additionally, the proportion of individuals aged 65 years and older is rapidly expanding, constituting 13.5% of the population in China [3]. This increase in life expectancy has coincided with a rapid expansion of the aging population, presenting a substantial public health challenge in fostering healthy aging and longevity. However, focusing solely on traditional determinants of longevity is insufficient, underscoring the importance of identifying other modifiable risk factors.

Oral diseases are widespread globally, affecting over 3.5 billion individuals [4,5], yet their influence on longevity is often overlooked. In addition to sociodemographic, genetic, and lifestyle factors [6], tooth loss—the ultimate outcome of oral diseases and a surrogate for overall health status—is essential for healthy aging as well. The retention of natural teeth over a lifetime is a fundamental aspect of overall well-being [7]. Tooth loss can be a potential risk factor for longevity that is independently related to the onset of disability and mortality in old age [7-9]. For instance, the 6-year mortality rate of

individuals with edentulousness (the lack of teeth) who do not use dentures was significantly higher than that of the individuals with ≥20 teeth [10]. Another study based on Baltimore Longitudinal Study of Aging indicated that being edentulous or having fewer than 20 teeth was independently associated with the mortality of older adults [11]. Centenarians comprise those who successfully age and have good resilience, and the number of centenarians is increasing worldwide [12-14]. Centenarians and their offspring demonstrated better oral health, suggesting the potential relationship between natural teeth retention and longevity [8]. Moreover, possessing ≤20 natural teeth was an independent risk factor for frailty among centenarians [3]. However, there is no cohort study that focuses on the impact of natural teeth retention on achieving centenarian status; thus, leveraging aging-focused, big data analytics to understand the intricate relationship among the older adult population becomes imperative.

The objective of this study was to prospectively investigate the association between edentulousness and the likelihood of becoming a centenarian in individuals aged 80 years and older, using data from the Chinese Longitudinal Healthy Longevity Survey (CLHLS)—an aging-focused, nationally representative cohort of the older Chinese population. These findings have the potential to inform interventions aimed at maximizing life expectancy.

Methods

Study Design and Population

The CLHLS is a comprehensive nationwide study that uses random sampling techniques to select participants from half of the counties and cities in 22 out of the 31 provinces across mainland China, covering approximately 85% of the total population [15]. The CLHLS collected data from 8 waves of surveys carried out in 1998, 2000, 2002, 2005, 2008, 2011, 2014, and 2018. Each survey round involved follow-ups with existing participants and the recruitment of new participants.

This cohort study used the baseline data from 1998, and the mortality follow-up data were from 1998, 2000, 2002, 2005, 2008, 2011, 2014, and 2018. As long as the individuals were aged 80 years or older in 1998, they could potentially live to 100 years in 2018. Thus, 6675 participants (aged ≥80 years and <100 years) who had the potential to age to 100 years or older were first included in this study. The participants who were lost to follow-up or had incomplete information on confounders were then excluded, and 4239 participants were included in the final analyses.

This study adheres to the STROBE (Standards for Reporting of Observational Studies in Epidemiology) guidelines [16].

Exposure Variable

The number of natural teeth of the participants was collected in the survey. Participants were divided into two categories based on the existence of natural teeth. The edentulous group was defined as participants with the complete loss of all dentition, while the nonedentulous group was defined as participants with at least 1 tooth.

Outcome Variable

Interviews were conducted with a close family member of the participants who had passed away between the previous wave's interview and the subsequent survey. The year of death and the age at death were collected. Individuals reaching the age of 100 years were defined as centenarians.

Covariates

Age in 1998, sex (male or female), ethnicity (Han Chinese or other), residence (urban or rural), marital status (currently married and living with a spouse, widowed, separated, divorced, or never married), exercise habits (yes or no), smoking status (nonsmoker, former smoker, or current smoker), alcohol use (nondrinker, former drinker, or current drinker), denture use (yes or no), diabetes (yes or no), hypertension (yes or no), stroke or cardiovascular disease (CVD; yes or no), and cancer (yes or no) were selected as covariates [6]. Denture use included the use of complete dentures and removable partial dentures [17]. All data were obtained by a face-to-face interview via a questionnaire by well-trained interviewers from the local Centers for Disease Control and Prevention.

Statistical Analysis

In the descriptive statistics, median and IQR were used for continuous variables, and frequency distributions were used for categorical variables. Continuous variables were compared by ANOVA tests for variables meeting the assumptions of normal distribution and homogeneity of variance, and by Kruskal-Wallis H test for those not meeting these assumptions. Categorical variables were compared using χ^2 tests. The univariate and multivariate logistic regression models were adopted to evaluate the odd ratios (ORs) and 95% CIs pertaining to the association between edentulousness and the likelihood of becoming a centenarian. To control for confounders, three logistic regression models were constructed to eliminate the influence of covariates. No variables were adjusted in model 1. Model 2 adjusted for the age in 1998, sex, ethnicity, marital status, smoking status, alcohol use, and exercise habits. Model 3 further incorporated adjustments for denture use, diabetes, hypertension, stroke or CVD, and cancer. Several sensitivity analyses were performed. First, a 1:1 propensity score matching (PSM) analysis was conducted to balance the differences between the edentulous and nonedentulous groups using the *MatchIt* R package [18], which adjusted for the age in 1998, sex, ethnicity, marital status, exercise habits, smoking status, alcohol use, denture use, diabetes, hypertension, stroke or CVD, and cancer. The data after PSM were then analyzed using logistic regression to confirm the association between edentulousness and the likelihood of becoming a centenarian, with only the covariates that were still significant after PSM being adjusted. Second, a 2-year lag analysis was conducted by excluding individuals whose follow-ups were less than 2 years. Third, the association between the number of natural teeth as a continuous variable and the likelihood of becoming a centenarian was explored by logistic regression models.

A 2-sided *P* value <.05 was considered statistically significant in all analyses. All statistical analyses were performed by R (version 4.3.1; R Foundation for Statistical Computing).

Ethical Considerations

Ethical approval was granted by the Biomedical Ethics Committee of Peking University (IRB00001052-13,074), and all participants or their proxy respondents provided informed consent without receiving financial compensation. The data have been anonymized to protect the privacy of participants.

Results

Baseline Characteristics of the Study Sample

As depicted in Figure 1, this study included 4239 participants from the CLHLS 1998‐2018. Table 1 demonstrated the baseline characteristics of these participants. Significant differences were detected among the participants in various factors, including age (P<.001), sex (P<.001), ethnicity (P=.03), denture use (P<.001), smoking status (P<.001), alcohol use (P<.001), and hypertension (P=.02). There were no significant differences between the two groups in terms of residence (P=.09), exercise habits (P=.87), diabetes (P>.99), stroke or CVD (P=.17), and cancer (P=.47). Overall, 607 (14.3%) of the 4239 individuals became centenarians during follow-up, and 264 (43.5%) of these 607 centenarians were edentulous.

Correlation Between Edentulousness and the Likelihood of Becoming a Centenarian

A significant association between edentulousness and the likelihood of becoming a centenarian was found among the participants. After adjusting for all covariates in model 3, the likelihood for becoming a centenarian increased in the nonedentulous group compared to the edentulous group (odds ratio [OR] 1.384, 95% CI 1.093 - 1.751; *P*=.007; Table 2).

Table . Association between edentulousness and the likelihood of becoming a centenarian.

Sensitivity Analyses

The robustness of the observed association was confirmed in the sensitivity analyses. PSM analysis was used to further evaluate the association between edentulousness and the likelihood of becoming a centenarian. Participants were divided into two groups for PSM analysis—the edentulous group and the nonedentulous group—and nearly all covariates were not significantly different after PSM (Multimedia Appendix 1). A significant increase in the likelihood of becoming a centenarian in the nonedentulous group was observed compared to the reference group (OR 1.272, 95% CI 1.037 - 1.561; *P*=.02; Table 3). Even after excluding participants who were followed up for less than 2 years, the association remained significant (OR 1.522, 95% CI 1.083 - 2.140; *P*=.02; Table 4). Regarding the association between the number of natural teeth as a continuous variable and the likelihood of becoming a centenarian, a notable positive association was found after adjusting for all covariates (OR 1.022, 95% CI 1.002 - 1.042; *P*=.03; Multimedia Appendix 2), which was comparable with the main results of this study.

Discussion

Principal Findings

In this large-scale cohort study, the association between edentulousness and the likelihood of becoming a centenarian among populations aged 80 years or older was comprehensively analyzed. The likelihood of becoming a centenarian increased for the nonedentulous group compared to the edentulous group. Importantly, the correlation persisted after PSM analysis and was confirmed by the 2-year lag analysis. A significant positive association was found between the number of natural teeth and the likelihood of becoming a centenarian, aligning with the primary findings of this investigation.

The outcomes of this study generally support previous research, suggesting that retaining natural teeth is linked to reduced mortality rates among individuals aged 80 years or older. A previous study indicated that a majority of centenarians expressed contentment with their oral health [19]. A cross-sectional study using data from the New England Centenarian Study unveiled a lower prevalence of tooth loss among centenarians compared to their peers at the ages of 65-74 years, hinting at tooth loss as a potential indicator of decreased longevity. Notably, both centenarians and their descendants exhibited superior oral health compared to the control group [8]. Another cross-sectional study that included 1034 centenarians from the CLHLS dataset indicated that having ≤20 natural teeth was an independent risk factor for frailty among centenarians [3], underscoring the significance of dental health for this age group. A population-based survey from Finland disclosed that even a small number of missing teeth could signify a heightened risk of overall mortality, emphasizing the link between tooth loss and mortality [20]. These findings align with the results of this study, and this research further enhances existing knowledge by showcasing that possessing natural teeth correlates with an increased likelihood of reaching centenarian status through extensive follow-ups and several sensitivity analyses. The robustness of this study was reaffirmed by a series of sensitivity analyses, as the association persisted after PSM analysis and was confirmed by the 2-year lag analysis. Upon examining the relationship between the number of natural teeth and the probability of attaining centenarian status, a significant positive correlation emerged. This association remained robust even after adjusting for all covariates, aligning with the principal findings of this study. These results underscore the importance of managing oral diseases, suggesting that older adults with natural teeth have a greater chance of becoming centenarians.

In this study, the OR changed from 0.646 to 1.384 from model 1 to model 3 for the correlation between edentulousness and the likelihood of becoming a centenarian, suggesting the existence of potential confounding factors. By adjusting the variables that were included in the model, age in 1998 was found to be the variable causing the OR to invert. Given that the outcome of this study was centenarian status, the age of the participants at enrollment could profoundly influence the outcome. Older individuals at enrollment were more likely to reach the age of 100 years. Therefore, to further mitigate this influence, a 2-year lag analysis was conducted in the *Sensitivity Analyses* section, excluding older individuals whose follow-ups were less than 2 years.

The precise mechanism underlying the higher likelihood of reaching centenarian status among individuals with natural teeth remains incompletely understood. Previous studies indicated an association between the number of teeth and masticatory function [21], and reduced chewing ability was related to premature death [22]. Individuals with edentulousness may have an unbalanced food selection, consuming inadequate amounts of fruits and vegetables, and their nutritional status may dispose these individuals to more chronic diseases [7,23], as the dietary intake pattern influences the microbial compositions and systemic inflammation [24].

This study demonstrates notable strengths by using longitudinal data from a sizable, nationally representative cohort of older Chinese individuals, enabling a prospective assessment of the link between edentulousness and achieving centenarian status in older adults. Furthermore, the study used various models that adjusted for multiple variables and conducted several sensitivity analyses to enhance the reliability of the results. Significantly, this research unveils, for the first time, the influence of edentulousness on the likelihood of becoming a centenarian. Nevertheless, this study is subject to various limitations. First, most lifestyle behaviors were self-reported, introducing potential measurement errors. Second, medical conditions were also self-reported, despite detailed explanations provided by trained interviewers during data collection. This method likely led to

an underestimation of disease prevalence, possible misclassification, and residual confounding due to unmeasured medical conditions [6]. Third, despite adjusting for numerous confounding factors, the association could still be influenced by unmeasured or residual confounders, such as nutrition status that may affect both dental conditions and lifespan. Fourth, there may be reverse causality in this study. Individuals in better health status are more likely to retain their teeth, potentially biasing the interpretation of the findings. Finally, the survivorship bias may exist, as the participants included were aged ≥80 years at baseline, which may represent a population in relatively better health and may not be fully representative of all older adults.

Conclusions

In this cohort study involving individuals aged 80 years or older in China, the presence of natural teeth was linked to an increased probability of reaching the age of 100 years, emphasizing the significance of preserving oral health even in advanced age. Implementing targeted intervention strategies for oral health to enhance overall well-being could potentially contribute to longevity. Further prospective research and basic research experiments are essential to validate these findings and illuminate the underlying mechanisms.

Abstract

Background: The global increase in life expectancy has not shown a similar rise in healthy life expectancy. Accurate assessment of biological aging is crucial for mitigating diseases and socioeconomic burdens associated with aging. Current biological age prediction models are limited by their reliance on conventional statistical methods and constrained clinical information.

Objective: This study aimed to develop and validate an aging clock model using artificial intelligence, based on comprehensive health check-up data, to predict biological age and assess its clinical relevance.

Methods: We used data from Koreans who underwent health checkups at the Seoul National University Hospital Gangnam Center as well as from the Korean Genome and Epidemiology Study. Our model incorporated 27 clinical factors and employed machine learning algorithms, including linear regression, least absolute shrinkage and selection operator, ridge regression, elastic net, random forest, support vector machine, gradient boosting, and K-nearest neighbors. Model performance was evaluated using adjusted R^2 and the mean squared error (MSE) values. Shapley Additive exPlanation (SHAP) analysis was conducted to interpret the model's predictions.

Results: The Gradient Boosting model achieved the best performance with a mean (SE) MSE of 4.219 (0.14) and a mean (SE) R^2 of 0.967 (0.001). SHAP analysis identified significant predictors of biological age, including kidney function markers, gender, glycated hemoglobin level, liver function markers, and anthropometric measurements. After adjusting for the chronological age, the predicted biological age showed strong associations with multiple clinical factors, such as metabolic status, body compositions, fatty liver, smoking status, and pulmonary function.

Conclusions: Our aging clock model demonstrates a high predictive accuracy and clinical relevance, offering a valuable tool for personalized health monitoring and intervention. The model's applicability in routine health checkups could enhance health management and promote regular health evaluations.

Introduction

Over the past several decades, global life expectancy has increased remarkably, rising from 66.8 years in 2000 to 73.4 years in 2019, according to the World Health Organization. However, healthy life expectancy has not kept pace, increasing only from 58.3 years to 63.7 years during the same period [1]. This demographic shift toward an aging population has led to increased health care dependency and associated social costs. The medical industry related to aging and the social costs thereof are continuously increasing [2]. Accurately assessing biological aging is a critical first step in mitigating age-related diseases and their socioeconomic impact.

Biological age refers to an estimation of an individual's physiological and functional status, reflecting the cumulative effects of genetic, environmental, and lifestyle factors on the aging process [3]. An individual with a biological age younger than their chronological age may have a lower risk of developing age-related diseases, while an older biological age could indicate a higher vulnerability to such conditions. This highlights the clinical significance of accurately estimating the biological age for personalized health interventions and monitoring. While numerous studies have explored the human lifespan [4,5], their evaluation is challenging due to the required long-term observations and limited clinical applicability.

Applying findings from academic studies to clinical practice remains challenging. Current biological age prediction models, primarily based on conventional statistical methods such as multivariate regression analysis, rely on limited clinical data, restricting their predictive power and insights into the aging process [5-8]. Recent advances have led to models using omics data [9], including DNA methylation [10], transcriptome [11], metabolome [12], and telomere data [9]. However, these models face implementation challenges in clinical settings due to their complexity and the difficulty in measuring omics markers. The model requires multiple molecular modalities and functional data to exhibit a superior performance [9]. In addition, it is challenging to quantify the dynamic effects of environmental, lifestyle, behavioral, and interventional factors on biological age.

In Asian countries, the health checkup industry has been growing substantially [13-15], with individuals regularly monitoring their health status. However, these checkups typically only indicate normal or abnormal conditions for individual tests, lacking comprehensive health status indicators. Providing biological age predictions through an aging clock could serve as a valuable tool for the health screening of patients, offering a comprehensive health status measure and encouraging regular checkup participation.

This study investigated the clinical relevance of artificial intelligence (AI)-predicted biological age in the Korean population using comprehensive health checkup data, examining its relationship with various clinical characteristics.

Methods

Participants and Datasets

The study investigated the healthy population participating in comprehensive health checkups at the Seoul National University Hospital Gangnam center, from 2003 to 2016. The initial baseline data were used, and the participants included a total of 81,211 Koreans, who comprised the Health and Prevention Enhancement (H-PEACE) cohort. The details of the H-PEACE cohort have been described previously [16]. To summarize, each participant completed a questionnaire on their past medical history and underwent anthropometric measurements and laboratory tests after at least 10 hours of fasting on the same day. We also used the data from the Korean Genome and Epidemiology Study (KoGES) from the Korean Center for Disease Control and Prevention as the replication set. From the KoGES data, we used the health examination cohort (KoGES HEXA data), which included past medical history, anthropometric measurement, and laboratory data [17]. Briefly, the KoGES HEXA cohort is a national health examinee registry, consisting of 173,357 urban Korean adults who underwent health checkup programs. We used clinical factors overlapping between factors from the H-PEACE cohort data and the KoGES HEXA data. The exclusion criteria to define the healthy adult super-control cohort were as follows: (1) participants diagnosed with diabetes, hypertension, or dyslipidemia; (2) participants drinking alcohol more than 14 g/week; (3) current or previous smokers; (4) those aged less than 30 years; and (5) those having a history of malignant disease. To check the clinical implication of the predicted biological age, we performed multiclinical feature association study in the gene-environmental interaction and phenotype (GENIE) study [16], which consisted of 123 clinical factors and gene datasets. We used the 116 clinical factors, excluding the 27 factors used to predict biological age, to determine the multiple associations with predicted biological age.

Development of a Biological Age Prediction Model

This study aimed to develop a widely applicable biological age model using only basic health screening parameters. The clinical features used to construct the biological age model were based on routine clinical measurements, including standard demographic features, blood test results, and anthropometric measurements, rather than the findings from expensive specialized examinations. The selection of clinical factors was constrained by the requirement that they be present in both the training dataset (H-PEACE cohort) and the replication dataset (KoGES HEXA cohort). Through this feature selection process, we used 27 clinical factors as inputs for predicting the biological age, which are gender, anthropometric measurements (height, weight, BMI, and waist circumference), metabolic status (levels of fasting glucose, glycated hemoglobin [HbA1c], uric acid, total cholesterol, triglyceride, high-density lipoprotein cholesterol, and low-density lipoprotein cholesterol), liver functions (albumin, total bilirubin, alkaline phosphatase, aspartate aminotransferase, alanine aminotransferase, and gamma-glutamyl transferase), complete blood cell counts (white blood cell count, red blood cell count, hemoglobin, hematocrit, and platelet count), calcium and renal function (levels of blood urea nitrogen and creatinine, and the glomerular filtration rate calculated using the chronic kidney disease epidemiology collaboration (CKD-EPI) equation [18]).

The true labels were defined as the chronological age of the super-control population, based on the assumption that chronological age aligns with biological age in physiologically standard individuals. This cohort was carefully selected to exclude individuals with pathological conditions, such as metabolic diseases or malignant diseases, as well as those exposed to environmental factors known to influence biological age, including smoking and alcohol consumption [19].

The baseline data of the H-PEACE super-control cohort was split into 80% as the training set and 20% as the testing set with stratification based on both age and sex. Specifically, age stratification was conducted by categorizing participants into

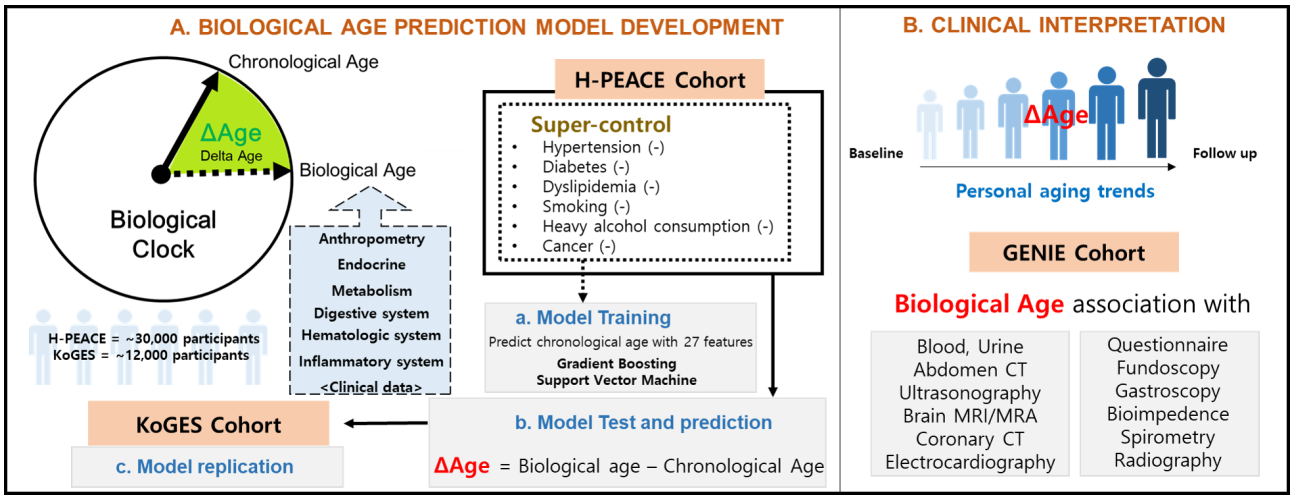
decade-based intervals, which were 20 - 29, 30 - 39, 40 - 49, 50 - 59, 60 - 69, 70 - 79, and more than 80 years. Five-fold cross-validation was performed to find the best hyperparameter for each model. We employed various machine learning models such as linear regression, least absolute shrinkage and selection operator (LASSO) regression, ridge regression, elastic net, random forest, support vector machine (SVM), gradient boosting, and K-nearest neighbors. These models were chosen for their ability to handle diverse relationships in data, including linear, nonlinear, and complex interactions. Hyperparameter optimization for each model was conducted using a grid search. To evaluate the performances of the developed models to predict biological age, we used adjusted R^2 and mean squared error (MSE) values. The evaluation results reported in this study are from 10 iterative experiments. A replication study was conducted in the KoGES HEXA dataset with the same experimental setting as the H-PEACE dataset. We interpreted the biological age prediction results using Shapley Additive exPlanation (SHAP) [20]. SHAP analysis was performed to elucidate the roles and impacts of different biological markers in predicting biological age.

Investigation of the Clinical Relevance of the Predicted Biological Age

We conducted linear regression analysis for multiple clinical factors using the GENIE study dataset with the predicted biological age, adjusting for chronological age. All reported *P* values were corrected for multiple tests using the Bonferroni correction.

The overview of the study is shown in Figure 1.

Figure 1. Overview of the study. H-PEACE: Health and Prevention Enhancement, KoGES: Korean Genome and Epidemiology Study, GENIE: gene-environmental interaction and phenotype, CT: computed tomography, MRI: magnetic resonance imaging, MRA: magnetic resonance angiography.



Ethical Considerations

The Institutional Review Board of the Seoul National University Hospital approved the study protocol and waived the need for informed consent (IRB number H-2005-223-1129). The study was performed in accordance with the Declaration of Helsinki. All patient data were deidentified before analysis, and strict confidentiality measures were implemented throughout the data collection, storage, and analysis processes. Access to the data was restricted to authorized research personnel only. The data management procedures complied with relevant data protection regulations to safeguard participants' privacy. No personally identifiable information was included in the final dataset or results.

Statistical and Computational Analyses

All analyses and calculations were performed using Python version 3.11.11 (Python Software Foundation). Multiple evaluation indices, including adjusted R^2 and MSE, β, and *P* value, were used to comprehensively evaluate the performances of the models and the significance of the associations. The statistical significance was based on a two-tailed *P* value of <.05.

Results

General Characteristics of the Participants

After applying the exclusion criteria to define the super-control cohort and removing the missing variables, we developed a model using a dataset collected from 28,417 individuals who underwent comprehensive health checkups at the Seoul National University Hospital Gangnam Center (ie, the H-PEACE cohort). The enrollment process is shown in Figure S1 in Multimedia Appendix 1. The mean (SD) participant age was 44.22 (11.26) years for 6467 men and 21,950 women. The baseline characteristics according to the aging of the study participants are shown in Table S1 in Multimedia Appendix 2. There were 1005 participants who were more than 65 years old and 27,412 who were 65 years old or less. Figure S2 in Multimedia Appendix 1 shows the chronological age distribution for the respective genders. Figure S3 in Multimedia Appendix 1 shows the distribution of gender in the training and test sets as well as the chronological age group distribution in the training and test sets.

Development and Performance of the Biological Age Prediction Model

The models were trained using 27 clinical variables on the full training dataset (80% of the super-control cohort), then predicted

on the test set (20%). For generalizability, 5-fold cross-validation with 10 iterative experiments were performed. The model was replicated using the KoGES HEXA data of 11,968 super-controls. Among 8 machine learning algorithms, the model showing the best performance was gradient boosting, for which the mean (SE) MSE value was 4.219 (0.140) and the mean (SE) R^2 value was 0.967 (0.001). The hyperparameters for the gradient boosting model were α=0.9, complexity parameter α=0, learning rate=0.1, maximum depth=5, and number of trees=500.

The second-best performing algorithm was the SVM model, with a mean (SE) MSE of 8.244 (0.210) and mean (SE) R^2 value of 0.935 (0.002). The performances of the 8 machine learning models in the test set are shown in Table 1.

Table . Comparison of the performances of 8 machine learning models to predict biological age in the test set (N=5684).

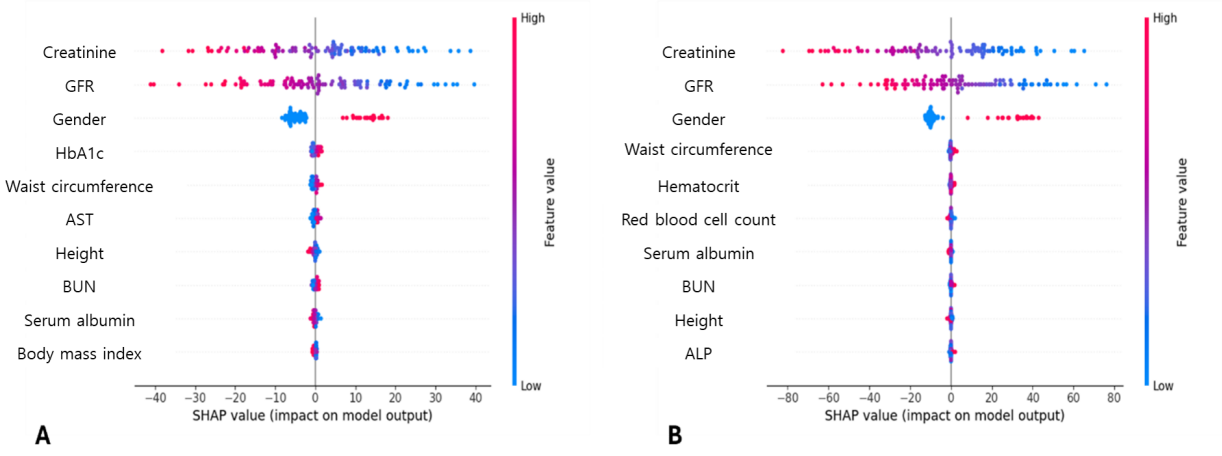
Model	Mean squared error, mean (standard error)	R^2, mean (standard error)
K nearest neighbor	63.829 (0.176)	0.497 (0.002)
Elastic net	50.518 (2.251)	0.602 (0.018)
Linear regression	50.314 (5.165)	0.603 (0.040)
LASSO[a]	50.271 (3.477)	0.604 (0.027)
Ridge	50.235 (5.047)	0.604 (0.039)
Random forest	20.941 (1.020)	0.835 (0.008)
Support vector machine	8.244 (0.210)	0.935 (0.002)
Gradient boosting	4.219 (0.140)	0.967 (0.001)

[a]LASSO: Least Absolute Shrinkage and Selection Operator.

The SHAP values from the gradient boosting and SVM models were analyzed to interpret their predictions of biological age. The SHAP values offer feature importance, providing the interpretation of the model's decision-making by quantifying the contribution of each feature to the model's output [20]. The corresponding visualizations are presented in Figure 2.

In the predictions of biological age generated by the gradient boosting model, the markers of kidney function, gender, HbA1c level, liver function, and anthropometric measurements were highlighted as significant predictors. In the SVM model, the SHAP summary plot revealed that kidney function markers, gender, liver function markers, red blood cell indices, and anthropometric measurements were the most influential predictors of biological age. These findings underscored the multifaceted nature of aging and highlighted the importance of maintaining optimal kidney function, metabolic status, and body composition in mitigating biological aging.

Figure 2. Visualization of the feature importance with Shapley Additive exPlanation (SHAP) values. SHAP summary plots for the model from the gradient boosting model (A) and the support vector machine (SVM) model (B) are visualized. Features with broader spreads and higher SHAP values have a more significant impact to predict biological age and values with the color gradient indicate whether higher or lower feature values are associated with increased biological age predictions. GFR: glomerular filtration rate, HbA1c: glycated hemoglobin, AST: aspartate aminotransferase, BUN: blood urea nitrogen, ALP: alkaline phosphatase.



Subgroup Analysis by Gender

The performances of the gradient boosting and SVM models were evaluated in the respective genders, male versus female participants. Applying the gradient boosting model to male participants, the mean (SE) MSE value was 5.258 (0.490). The SHAP value was significantly influenced by renal function, metabolic status, red blood cell indices, and anthropometric measurements. In female participants, the mean (SE) MSE value was 2.743 (0.099) and the SHAP values with the highest impact were similar to those for the male participants. The performances in the SVM and SHAP plots for male and female participants

are shown in Table 2 and Figure S4 in Multimedia Appendix 1.

Table . Comparison of the performances of the test set and replication set in all ages and in age above 65 years.

Dataset	Subgroup	Gradient boosting		Support Vector Machine	
		All ages	Age above 65 years	All ages	Age above 65 years
		MSE[a]	MSE[a]	MSE[a]	MSE[a]
Test set	Male and Female	4.219 (0.140)	18.942 (1.250)	8.244 (0.210)	18.077 (1.094)
Replication set	Male and Female	2.406 (0.083)	2.190 (0.085)	7.838 (0.065)	3.116 (0.148)
Test set	Male	5.258 (0.490)	20.357 (2.493)	15.476 (0.652)	20.678 (1.504)
Replication set	Male	2.032 (0.110)	2.096 (0.113)	6.337 (0.053)	3.143 (0.205)
Test set	Female	2.743 (0.099)	17.153 (0.819)	7.955 (0.170)	18.928 (1.698)
Replication set	Female	16.050 (0.467)	3.746 (0.366)	37.301 (0.777)	3.832 (0.510)

[a]Mean squared error (MSE) values are shown as mean (standard error).

Replication of the Developed Biological Age Prediction Model

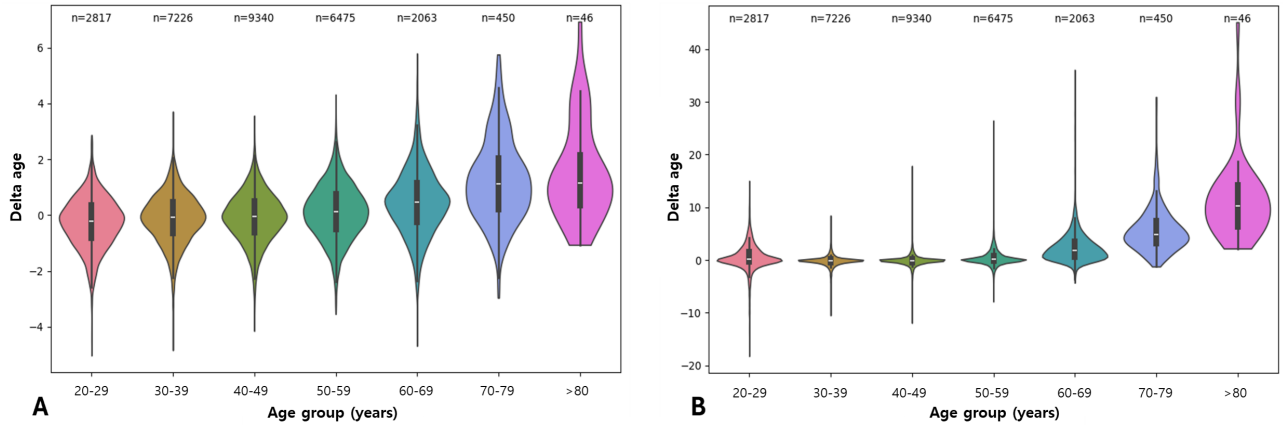
We replicated the model with the gradient boosting and SVM models using the KoGES HEXA data for participants of all ages and those under 65 years of age. The prediction model was better replicated in male participants and those aged above 65 years. The replicated results are shown in Table 2.

Delta Age Evaluation Using Baseline and Follow-Up Data

The model predicted the biological age in the test set (20% of the total dataset; 5684 individuals). The delta age, which is the difference between the biological age and the predicted biological age, was calculated for all individuals in the test dataset.

Figure 3 shows the delta age distribution across the different age groups, and Figure S5 in Multimedia Appendix 1 shows the delta age distribution across different age groups in each gender.

Figure 3. The delta age distribution across different age groups. The distribution of the delta age across different age groups in the test set at baseline (total n=5684) is shown for the gradient boosting (A) and support vector machine (B) models.



With the increase in the age groups, there was an observable pattern in the variability of delta age. In the younger age group (the 1st to the 3rd groups), there was increased variability, suggesting diverse aging processes influenced by multiple factors such as genetics, lifestyle, and health conditions. Older groups (the 7th and 8th groups) showed less variability and more positive values of delta age, possibly reflecting a selection of healthier individuals who have managed to reach older ages. The results were consistent in each gender group as well.

Among 5684 baseline participants, there were 2022 participants who had follow-up data, with follow-up duration ranging from 1 to 10 years (with 0 meaning the same age at two consecutive visits).

Figure 4 shows the projectiles of the changes in delta age during follow-up across different age groups in the test set (n=2022) for the gradient boosting and SVM models. While the younger age groups exhibited stable biological aging trajectories, the middle-aged and older groups showed increased variability and accelerated aging over the follow-up period. The observed trends were consistent across both the gradient boosting and SVM models, providing robust evidence for the described aging patterns.

Figure 4. The delta age trajectory during follow-up across different age groups. The projectiles of the changes in delta age during follow-up across different age groups in the test set (n=2022) are shown for the gradient boosting model (A) and SVM model.

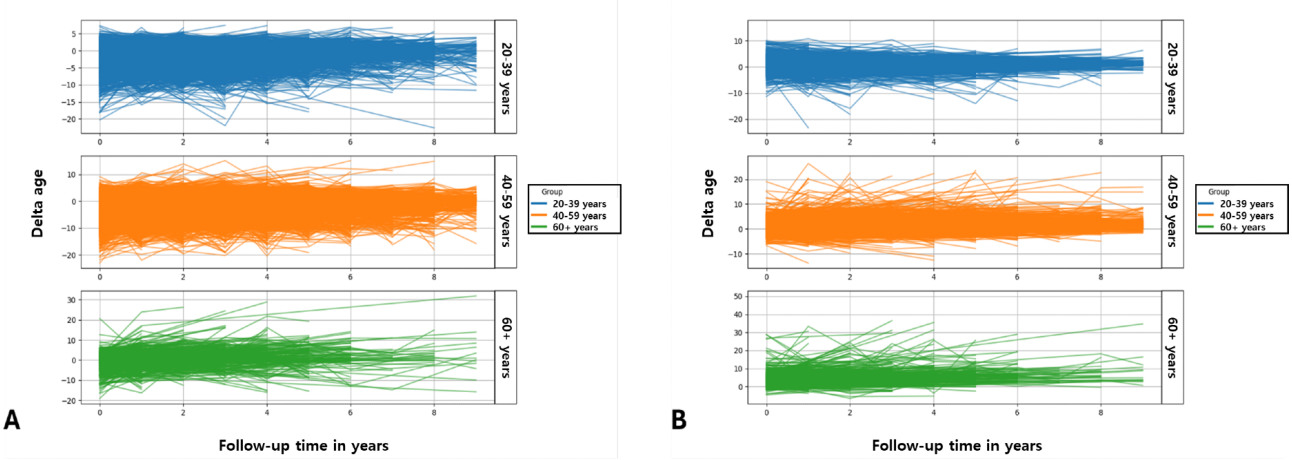


Figure S6 in Multimedia Appendix 1 shows the trajectory of the changes in delta age during follow-up across different gender groups in the test set at baseline (n= 5684) for the gradient boosting model and SVM model.

Clinical Interpretation Using a Multiple Clinical Factor Association Study

To explore the clinical relevance of the predicted biological age, we performed a phenome-wide association analysis between 116 phenotypes corroborated by comprehensive health checkups from the GENIE study dataset and the output of the predicted biological age model (data for both genders are shown in Table S2 in Multimedia Appendix 2, data for the male gender are shown in Table S3 in Multimedia Appendix 2, and data for the female gender are shown in Table S4 in Multimedia Appendix 2).

We found that the predicted biological age was significantly associated with 50 clinical factors after Bonferroni correction (Tables S2-S4 in Multimedia Appendix 2). Notably, the most significant associations were observed with metabolic status, body composition, fatty liver, smoking status, and pulmonary function, after adjusting for the chronological age. Table 3 shows the top 10 significant results in both genders, in male participants, and in female participants. The correlations among the variables are shown in Figure S7 in Multimedia Appendix 1. These findings suggest that the predicted biological age, developed from multiple clinical factors from comprehensive health checkups, may also possess predictive capabilities for aging in various organs.

Table . Top 10 significant clinical factors associated with the predicted biological age.

Clinical factors	Study modality	N	β	*P* value
In both genders				
Diabetes diagnosis	Questionnaire	10,351	−.002	1.75×10^{-270}

Discussion

This study underscores the clinical relevance of biological age as predicted by AI using comprehensive health checkup data. Our findings elucidate the clinical relevance of biological age—as assessed through machine learning models—which exhibits strong associations with multiple clinical factors, thereby providing valuable insights into the aging process and its implications on health. The result demonstrated that the best-performing model, gradient boosting, achieved a mean (SE) MSE value of 4.219 (0.140) and mean (SE) R^2 value of 0.967 (0.001), indicating acceptable predictive accuracy. Additionally, the SHAP analysis highlighted markers such as kidney function, gender, HbA1c level, liver function, and anthropometric measurements as significant predictors of biological age. These findings suggest that biological age is a multifaceted construct influenced by various physiological factors and can serve as a robust indicator of the overall health status. The identification of these markers is significant because it supports the importance of maintaining optimal kidney function, metabolic health, and body composition in mitigating biological aging. This comprehensive understanding can lead to more targeted and effective interventions aimed at improving overall health and longevity.

Our study findings align with existing research findings that emphasize the utility of biological age as a comprehensive health indicator [21-23]. Previous studies have also identified the importance of factors such as kidney function [24], metabolic health [25,26], and inflammatory markers [27,28] in the aging process. However, our use of machine learning models such as the gradient boosting model and the SVM model provides a more nuanced understanding of how these factors interact to influence biological age, setting our research apart from traditional statistical methods. For instance, while existing literature has demonstrated the importance of individual biomarkers, our approach integrates multiple clinical variables to provide a holistic prediction model.

The use of multiple machine learning algorithms allowed for a comprehensive evaluation of their predictive capabilities. The gradient boosting model outperformed other algorithms, with performance R^2 of 0.967 and MSE of 4.219, due to its ability to handle nonlinear relationships and feature interactions, which are crucial in modeling complex biological systems [29]. Unlike linear models such as the ridge or LASSO regression, the gradient boosting model iteratively optimizes residual errors, capturing intricate dependencies between features. Its robustness to outliers and noise further enhances performance, making it particularly suited for real-world health checkups [30,31]. The generalizability of gradient boosting, demonstrated in both the training and replication datasets, underscores its potential for clinical application. Future studies should explore hybrid approaches to integrate the strengths of the gradient boosting model with more efficient models for broader use.

In the SHAP analysis, kidney function emerged as a significant predictor of biological age, consistent with its established role as an indicator of systemic health [32]. The decrease in kidney function is closely associated with aging-related changes, such as a reduced glomerular filtration rate and increased risk of chronic kidney disease [33]. These conditions often signify cumulative damage from metabolic stressors, hypertension, and other age-related factors [34]. The inclusion of kidney function markers, such as creatinine and the estimated glomerular filtration rate, in our model highlights their critical contribution to capturing the physiological aging process. Maintaining optimal kidney function could therefore serve as a target for mitigating biological aging and reducing the burden of associated comorbidities.

The body composition, including markers such as waist circumference and BMI, was another key contributor identified on SHAP analysis. This finding underscores the impact of adiposity and muscle mass on aging trajectories. Increased visceral fat and reduced skeletal muscle mass are hallmark features of sarcopenic obesity, a condition linked to metabolic dysfunction and accelerated biological aging [35,36]. Such changes exacerbate systemic inflammation and insulin resistance, further compounding aging-related risks [37,38]. The identification of body composition as a significant predictor emphasizes the importance of lifestyle interventions, such as exercise and dietary modifications, to preserve muscle mass and manage body fat. By integrating these markers into the prediction model, our study highlights their multifaceted roles in biological aging. Kidney function and body composition serve not only as indicators of systemic health but also as modifiable factors, offering potential avenues for personalized health interventions aimed at slowing biological aging and promoting longevity. This enhanced understanding enriches the clinical utility of our model and provides actionable insights for practitioners.

Visualization of the delta age distribution across different age groups shows that there is increased variability in the younger age group and less variability and a more positive value of delta age in the older group. This pattern underscores the importance of middle age as a critical period for implementing health interventions to manage biological aging effectively, and the need for focused care strategies to manage aging-related health issues in older adults.

In the multiple clinical factor association study for predicted biological age, we found that the predicted biological age was significantly associated with 50 clinical factors even after the adjustment of chronological age. The most significant associations were observed with the metabolic status, body composition, fatty liver, smoking status, and pulmonary function. These associations highlight the clinical relevance of biological age as a comprehensive marker of an individual's health status and suggest potential pathophysiological mechanisms accompanying the aging process. Reduced pulmonary function is known to be an indicator of systemic aging and has been linked to increased mortality and morbidity in older adults [39,40]. This suggests that maintaining optimal lung function could be crucial in mitigating the effects of biological aging and improving overall health outcomes.

The association between smoking status and predicted biological age is well-documented in various studies. For example, research using AI to analyze blood data from 149,000 adults revealed

that smokers exhibit a faster rate of biological aging compared to nonsmokers [41]. Remarkably, female smokers were predicted to have a biological age twice that of their chronological age [42]. These findings emphasize the detrimental impact of smoking on biological age. Additionally, exposure to tobacco during early life has been linked to accelerated biological aging in adulthood [43]. The underlying mechanisms include inflammation [44,45], epigenetic changes [46], and chromosomal damage [47]. These results underline the potential for biological recovery after cessation, aligning with prior research and emphasizing both the dangers of smoking and the benefits of quitting.

Body composition changes, including increased body fat, decreased muscle mass, and higher BMI, were also significantly associated with biological age. These findings align with previous studies that have shown that sarcopenia (loss of muscle mass) and obesity are critical factors in the aging process [48]. Excess body fat, particularly visceral fat, is associated with metabolic syndrome, cardiovascular diseases, and insulin resistance, all of which contribute to accelerated biological aging [49,50]. Conversely, maintaining muscle mass is essential for physical function and metabolic health, highlighting the importance of exercise and nutrition in managing the biological age. These findings also provide insights into the pathophysiological aspects of aging, suggesting that targeted interventions in these areas could potentially mitigate the adverse effects of aging and improve health outcomes.

The results have significant implications for health care and aging research. By providing a comprehensive measure of biological age, health care providers can better assess an individual's overall health status and identify potential risks for age-related diseases. This approach could also facilitate more personalized health care strategies, improving patient outcomes and quality of life. Furthermore, the findings contribute to the broader understanding of the aging process, offering valuable insights for researchers aiming to develop innovative strategies to overcome age-related diseases and enhance healthy aging.

Despite the robust findings, there are limitations to consider. The study population was predominantly Korean, which may limit the generalizability of the results to other ethnic groups. Additionally, the reliance on clinical data from health checkups may not capture all factors influencing biological age, such as genetic predispositions or epigenetic clocks and environmental influences. Future studies should aim to include more diverse populations and incorporate additional variables to enhance the comprehensiveness and applicability of the models. Furthermore, longitudinal studies are needed to validate the long-term predictive capabilities of the models and their effectiveness in different health care settings.

In conclusion, our study demonstrates the clinical relevance of biological age as predicted by machine learning models. The findings provide valuable insights into the aging process and highlight the potential of biological age as a comprehensive health indicator. Future research should focus on refining these models and exploring their applicability in diverse populations to further enhance their utility in clinical practice. The integration of advanced machine learning techniques with comprehensive health data holds great promise for advancing our understanding of aging and improving health care outcomes.

Abstract

Background: The rising prevalence of mental health conditions such as depression and anxiety among the aging population underscores the need for accessible and effective psychosocial support, particularly for community-dwelling older adults who face barriers like social stigma and limited mental health literacy. Peer volunteers have emerged as a promising resource to support these individuals; yet, they often lack the requisite training for effective intervention.

Objective: This study aims to explore the experiences of peer volunteers who participated in a Psychological First Aid training program.

Methods: Using a descriptive qualitative research design, semistructured interviews were conducted with 13 older adults between September and October 2024, and data were thematically analyzed.

Results: Three themes were identified: (1) dimensions of volunteerism from motivations to resistance, (2) empowerment through collaborative learning, and (3) recommendations for designing inclusive, holistic training programs.

Conclusions: The findings of this study showed positive outcomes such as personal growth and strengthened social connections among participants. However, enhancements in teaching methods, logistical arrangements, and session regularity are recommended to optimize the Psychological First Aid program. These insights can guide the development of more robust training models to support both peer volunteers and the older adult communities they serve.

KEYWORDS

psychological first aid; PFA training; peer volunteers; mental health; psychosocial support; older adults

Introduction

The global population of older adults has grown significantly in recent years. In Singapore, the proportion of citizens aged 65 years and older increased to 19.1% in 2023 and is projected to reach 24.1% by 2030 [1]. Globally, approximately 14% of older adults live with mental health conditions, with depression and anxiety being the most common [2]. This trend is mirrored in Singapore, where issues such as depression, dementia, and subsyndromal depression are increasingly prevalent among older adults [3]. Social isolation, multimorbidity, and low socioeconomic status have been identified as key contributors to the development of mental health conditions in older adults. These factors are associated with severe consequences, including increased suicide risk, diminished quality of life, and heightened susceptibility to cognitive disorders such as dementia [4-7]. Unfortunately, mental health conditions in this population often remain undiagnosed or underreported due to stigma and limited mental health literacy, leading to delays in treatment and intervention [8,9].

Volunteerism has been recognized as an effective approach to improving the mental well-being of older adults. Programs such as AmeriCorps Seniors and Age UK internationally, and SG Cares and Lions Befrienders locally, provide platforms for older adults to engage socially and meaningfully, helping to reduce social isolation and promote active aging [10-15]. Despite these benefits, studies conducted in Portugal and the United Kingdom reveal that volunteers often face challenges due to insufficient training to support individuals with mental health conditions [16,17]. Structured training programs have been increasingly recognized for their ability to prepare peer volunteers to provide effective psychosocial support. Peer volunteers' training has been widely used in various settings to help individuals cope with potentially traumatic events, reduce distress, and foster a

sense of safety while supporting others [18,19]. Such programs have also proven beneficial not only in humanitarian aid situations but also in enhancing volunteers' ability to offer timely, empathetic, and informal support [20,21]. Formal training equips volunteers with the knowledge and skills necessary to provide effective support to individuals in distress while also addressing the volunteers' own needs [22].

However, most studies examining peer volunteer training have been conducted in Western contexts, highlighting a critical gap in understanding its application and effectiveness in Asian settings [23-25]. Given that Asian cultures are deeply rooted in collectivism and family-centered caregiving, there is strong evidence that Western models shaped by individualism and structured volunteer systems may not fully translate to these contexts [26]. Considering the growing prevalence of mental health conditions among Singapore's older adults and the potential benefits of formal training programs, there is an urgent need to implement and evaluate such initiatives locally.

This study aims to explore the experiences of peer volunteers who participated in a Psychological First Aid (PFA) training program designed to support community-dwelling older adults in Singapore. Specifically, it addresses the research question: "What are the experiences of peer volunteers who completed the PFA programme?" The findings will inform the refinement of culturally relevant and effective training strategies to enhance psychosocial support for both volunteers and the older adult population in Singapore.

Methods

Study Design

A descriptive qualitative research design was used to explore the experiences of peer volunteers who participated in a PFA program. The use of a qualitative design is prudent as it allows participants to share "thick" or "rich" descriptions, providing deeper insights into subjective topics [27]. The Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist guided the reporting of this qualitative study [28] (Table S1 in Multimedia Appendix 1).

Sampling Strategy and Eligibility

Convenience sampling was used to recruit eligible participants who met the following criteria: (1) older adults aged 50 to 95 years, (2) participated in the PFA program, and (3) spoke and read English.

PFA Program

The PFA program was developed based on foundational literature [29-31] and insights from a multidisciplinary research team. This team comprised psychiatrists, psychologists, nurses, and peer volunteers with extensive experience supporting community-dwelling older adults. Their prior primary and secondary research studies formed the basis of the PFA intervention design.

The program consisted of 4 half-day workshops, each lasting 4 hours, and conducted face-to-face over consecutive weekends. The workshops were held in a conducive community space and addressed a range of topics, including common mental health disorders in Singapore, psychosocial needs of older adults and peer volunteers, skills in empathetic listening, low-intensity psychological support, mindfulness training, identifying individuals at risk, and strategies for facilitating connections to professional care.

Workshops were delivered by a diverse team of trainers, including psychiatrists, nurses, experienced peer volunteers, and mindfulness instructors. Peer volunteers involved in earlier training sessions also contributed as facilitators, adding a practical perspective to the training content. The primary objective of the PFA program was to enable early detection of mental health issues among community-dwelling older adults. By equipping volunteers with these skills, the program also aimed to enhance the resilience and coping strategies of both the older adults and the volunteers themselves.

Ethical Considerations

The study received ethical approval from the institutional review board of the National University of Singapore (NUS-IRB-2024 - 506), which serves as the ethics board for the participating institution. Prior to recruitment, participants were provided with detailed information sheets outlining the study's objectives and their roles. Written informed consent was obtained, and voluntary participation was emphasized. To ensure anonymity and confidentiality, each participant's data were coded using unique serial numbers ranging from 1 to 13.

Data Collection

Data collection for the study was conducted between September and October 2024. All 20 peer volunteers who participated in the first batch of the PFA program were invited to join the study. Invitations were extended by a study administrator independent of the research team. Volunteers who expressed interest were introduced to the research team. A male research assistant (independent of the PFA program and participants) explained the study details to the interested participants, provided the participant information sheet, and obtained written informed consent. Subsequently, one-on-one interviews were arranged. Participants could choose between web-based or in-person interviews based on their preference. Before the interview, sociodemographic data such as age, gender, citizenship, ethnicity, religion, marital status, number of children, education level, employment status, and volunteering duration were collected.

A male research assistant (JS) with a BSc (Hons) in Nursing and no dependent relationship with the participants, developed the semistructured interview guide guided by literature review [32,33] and conducted the interviews to ensure consistency. Additionally, the same research assistant recorded field notes during each session. The guide included open-ended questions focusing on participants' experiences with the PFA program and their volunteerism journey (eg, "Would you like to share any personal experiences or stories that inspired you to join this PFA programme?" and "How was your experience with the PFA programme?"). All interviews were conducted via Zoom (Zoom Video Communications), and consent was obtained from participants for audio and video recording. Transcripts were transcribed verbatim from the recordings. To ensure rigor, the

research assistant (JS) received qualitative research training under the guidance of a PhD-trained researcher (SS) with extensive qualitative experience. A pilot interview was conducted with one peer volunteer to evaluate the interview guide's flow and relevance, aligning it with the research objectives; no modifications were needed, and the data from this pilot interview was included in the analysis as it contributed valuable insights to the study. A total of 13 interviews were conducted with no attrition, with durations ranging from 36 to 101 minutes (mean of 59.5 min). Data saturation was reached after the 11th interview, as no new concepts emerged [34]. Two additional interviews were conducted to confirm saturation. The interview guide is provided in Table S2 in Multimedia Appendix 1.

Data Analysis

The data were analyzed using Braun and Clarke's [35] 6-step framework for inductive thematic analysis. The process began with the verbatim transcripts being imported into Microsoft Word for organization and management. Two researchers (JS and SS) independently familiarized themselves with the data by reading and rereading the transcripts to gain a thorough understanding. Initial codes were generated by identifying meaningful units of information and relevant concepts within the data. These codes were systematically applied across all transcripts. Through an iterative process, the researchers grouped the codes into broader categories to develop initial themes and subthemes. These themes reflected the key patterns and narratives emerging from the data (Table S3 in Multimedia Appendix 1). The coding and thematic development were continuously refined through team discussions to ensure accuracy and depth. Any discrepancies in interpretation were resolved through consensus, ensuring a comprehensive and cohesive representation of the findings.

Rigor

To ensure the rigor of this study's findings, credibility, transferability, dependability, and confirmability were prioritized, as outlined by Cypress [36]. Credibility was maintained through prolonged engagement with participants during data collection and investigator triangulation during data analysis. This allowed for multiple perspectives to be considered and verified against the data. Transferability was established by providing thick, rich descriptions of participants' experiences with the PFA program, supported by direct quotes. This approach enables readers to evaluate the applicability of the findings to other contexts. Dependability was reinforced by creating an audit trail, which included comprehensive documentation of interview transcripts, coding, and the analytical process. This ensures that the study can be independently reviewed and verified. Confirmability was achieved using a reflexive journal throughout the research process. Reflexivity, as highlighted by Teh and Lek [37], is a critical aspect of qualitative research that minimizes the influence of unconscious researcher biases during data interpretation. By maintaining this journal, the researchers ensured their reflections and decisions were transparent, bolstering the trustworthiness of the study [38].

Results

Overview

A total of 13 community-dwelling older adults participated in this study, and their sociodemographic characteristics are presented in Table 1. The mean age of the participants was 61.2 (SD 6.9) years. Most participants were female (9/13, 69%) and married (9/13, 69%), with all of them were Singaporeans (13/13, 100%). The group was predominantly composed of Malay (6/13, 46%) and Chinese (5/13, 38%) ethnic backgrounds. The participants' employment status varied, with being retired (4/13, 31%), employed full-time (4/13, 31%), employed part-time (2/13, 15%), unemployed (2/13, 15%), and self-employed (1/13, 8%). The group had a balanced distribution of volunteerism experience, with 54% (7/13) having up to 1 year of experience, and 46% (6/13) having more than 1 year of experience.

Three themes were identified from the data analysis, highlighting older adults' experiences of the PFA program and the value it added to their volunteerism journey: (1) dimensions of volunteerism from motivations to hurdles, (2) empowerment through collaborative learning, and (3) recommendations for designing inclusive, holistic training programs. These themes were further supported by 9 subthemes (Figure 1).

Table . Participants' sociodemographic characteristics (n=13).

Sociodemographic variables	Values
Age (years), mean (SD)	61.2 (6.9)
Sex, n (%)

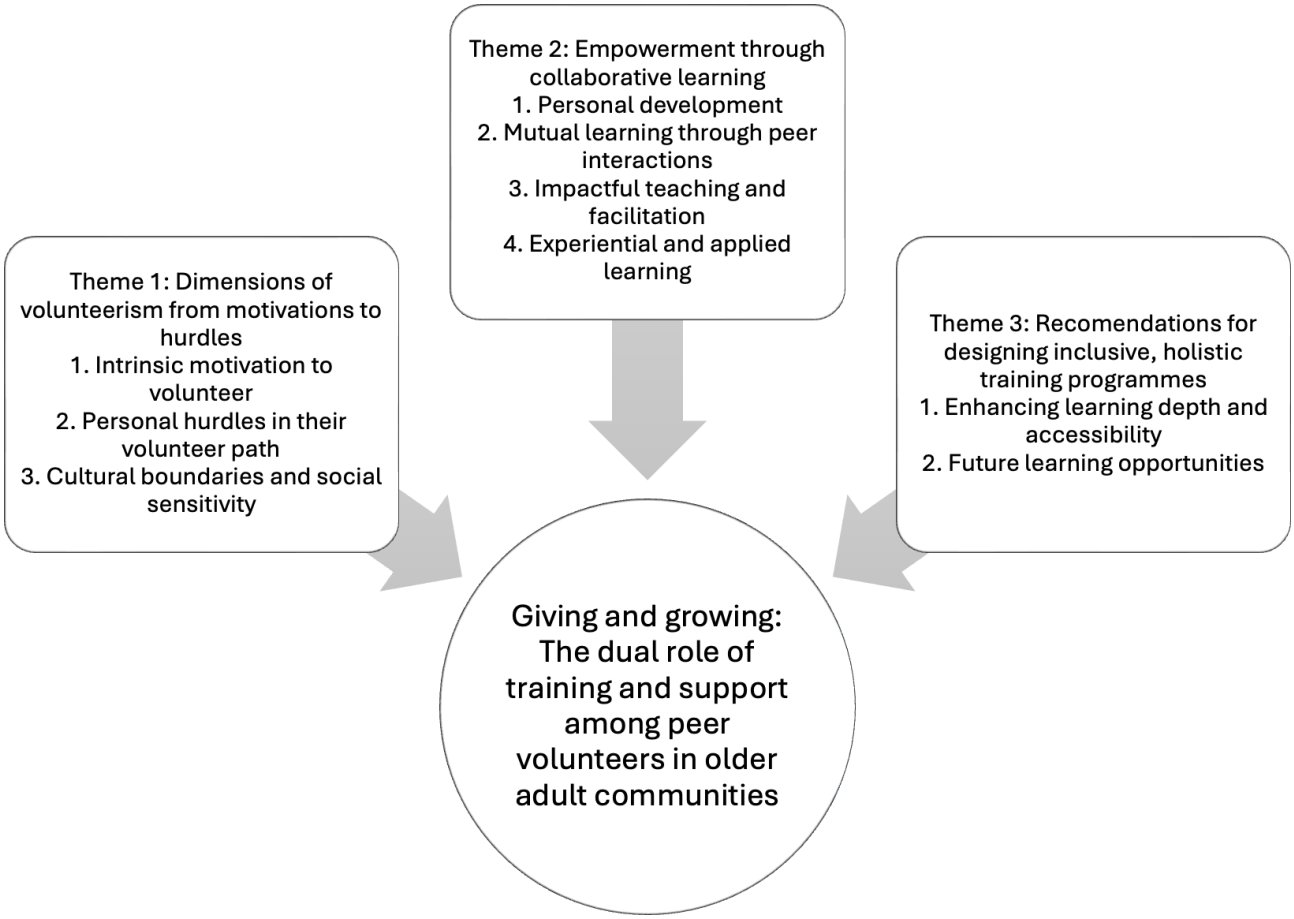
Figure 1. Older adults' experience on the Psychological First Aid program and personal volunteering experience.



Theme 1: Dimensions of Volunteerism From Motivations to Hurdles

Overview

This theme highlighted older adults' experiences from motivations to hurdles, which shaped both their initial decision to volunteer and their continued commitment. These were categorized into 3 subthemes: intrinsic motivation to volunteer, personal hurdles in their volunteer path, and cultural boundaries and social sensitivity.

Intrinsic Motivation to Volunteer

Most older adults shared their personal motivations for volunteerism. As the majority of older adults were either employed part-time or retirees, they had free time available. Hence, they expressed a strong desire to actively engage with the community to enhance their personal well-being by giving back to society and fostering friendships. Many older adults also shared the perceived benefits of volunteerism, from keeping their minds active and serving as a protection to prevent the onset of dementia.

> *I volunteer as It's to help myself to prevent having dementia because I'm learning something new...* [K3, Female peer volunteer]

> *I volunteer as It's to help myself to prevent having dementia because I'm learning something new...* [K3, Female peer volunteer]

Some older adults attributed their volunteerism motivations to the cultural values instilled by their families. They were raised by their parents to be benevolent and gracious, which fostered a strong desire to give back to society. As a result, the concept of volunteerism became deeply embedded in their upbringing.

> *I see my father as a figure who do all this volunteer work in his life.… so it's already in my blood* [K5, Female peer volunteer]

Older adults attributed their decision to join the PFA program to the influence of their peers, highlighting the positive impact of fostering a sense of purpose and building meaningful friendships. For instance, one participant, who became a single mother during her teenage years, recounted the emotional struggles she faced, such as limited support from her family and peers, which negatively affected her emotional health. Having developed emotional resilience through overcoming these challenges, she felt inspired to volunteer and provide emotional support to others navigating similar difficulties.

> *To help people because I had gone through a period of time [her teenage years] and from that time, it makes me want to touch more and especially on single moms* [K13, Female peer volunteer]

Older adults shared that establishing meaningful engagement with their community residents was a significant challenge. Many encountered resistance when attempting to approach and offer support. Observing the reluctance of fellow older adults to seek help underscored for them the importance of acquiring

proper training. They recognized that such training was crucial to effectively support and connect with others in their communities.

> *I think it's the resistance of the people like when we try to talk or whatever, there is certain resistance… that led me to learn more from this programme* [K11, Female peer volunteer]

Personal Hurdles in Their Volunteer Path

Older adults highlighted the struggle of physical limitations, such as the lack of strength, despite being motivated to attend training courses to support others. This is an important consideration, as most community residents are older adults who may need assistance moving from one place to another. One participant shared that, due to her age and physical build, she is not as strong as she was in her youth and therefore needs to be more cautious when interacting with the older community residents or attending any courses.

> *I don't have much strength, things are very physical. I would not be able to help because … we may need to provide them physical support, like to support them so that they don't fall down...maybe emotional support would do better [for me]…* [K3, Female peer volunteer]

In addition, one participant shared that he was diagnosed with aphasia. This gravely impacted his communication abilities with both his peers and community residents. As a result, he struggled to express his needs efficiently.

> *Sometimes my train of thoughts go out... sometimes when people talk to me, I can't interpret properly… that sometime dampen me from opening up…* [K10, Male peer volunteer]

Cultural Boundaries and Social Sensitivity

Many older adults identified cultural perceptions as a significant barrier in their volunteerism experiences. They faced cultural taboos, such as Muslims' discomfort with certain terms used around older adults, including "forgetful" and concerns about interacting too much with the opposite gender. As a result, the volunteers, especially those of different ethnicities, had to be mindful of their behavior when approaching the community-dwelling older adults. Additionally, some volunteers highlighted that Muslim residents in the community often exhibit caution towards "outsiders" and show a preference for staying within their own social and ethnic circles, which limits their willingness to engage with others. These cultural dynamics present challenges in fostering broader social connections and offering support.

> *For the Malay elderly how we want to get them, how are we going to approach them to ask them that, we can really give them help. That's our challenge now.* [K13, Female peer volunteer]

Gender dynamics were frequently discussed by older adults, who reported that supporting members of the opposite gender was often challenging and required careful consideration, particularly regarding body language and posture. Many volunteers found it easier to assist individuals of the same gender, such as a female peer volunteer supporting a female older adult, as they could more easily interpret nonverbal cues like body language and gestures. One female peer volunteer shared her discomfort when a male community resident exhibited inappropriate behavior, such as touching without consent. These gender-related challenges highlight the complexities involved in volunteer interactions and the need for sensitive handling of such situations in community support roles.

> *Not easy to understand a male, what he's thinking. A female, when you look into her eyes, you talk to her, you can understand more… not easy with males….* [K1, Female peer volunteer]

Many felt the need for a chaperone, especially when interacting with the opposite gender, as a safety measure and to prevent unnecessary conflict. In one instance, one female peer volunteer experienced negative experiences from a wife due to her close rapport with the community resident.

> *There is a gender difference [in our local setting] that we need to be more mindful. For female, we can touch the female, can consult but for male, we need to be more careful, more mindful on our gesture.* [K11, Female peer volunteer]

Theme 2: Empowerment Through Collaborative Learning

Overview

This theme highlighted elements that contributed to the empowerment of older adults through collaborative learning during the PFA program. These were supported by 4 subthemes as follows: personal development, mutual learning through peer interactions, impactful teaching and facilitation, and experiential and applied learning.

Personal Development

Older adults highlighted the benefits of participating in the PFA program. Many expressed how the knowledge acquired through the PFA program helped them in real-life situations, enabling them to better showcase their skills as peer volunteers. Topics such as grief and mindfulness were essential in their role as peer volunteers. This, in turn, fostered a sense of empowerment and personal growth among the older adults.

> *It Was Nice, It Was Very Knowledgeable. I Must Say We Learn a Lot* [K1, Female Peer Volunteer]

Additionally, the older adults reported maintaining a positive attitude toward learning. They expressed that learning is a continuous journey, and the knowledge they gained expanded their viewpoints.

> *The… workshop where it really broadened our mind and then we learn more about things [eg how to support others better].* [K2, Male peer volunteer]

Mutual Learning Through Peer Interactions

Older adults emphasized that the PFA program highlighted the importance of maintaining open and effective communication among peers. Through interactions during class and breaks,

they had the opportunity to share personal experiences, which many participants found invaluable. This peer exchange allowed them to learn from each other's experiences and mentally prepare for similar real-life situations in the future. The older adults also expressed that the learning process was reciprocal, with everyone eager to contribute and learn from one another.

> *You get different ideas from them [peers attending PFA programme]. You learn more things from them, they learn from you.* [K1, Male peer volunteer]

Additionally, some older adults shared that the class, which included individuals from various ethnic backgrounds such as Chinese, Malay, and Indian, provided a valuable opportunity to engage with and learn about different cultural practices. This allowed them to conceptualize and compare the differences or similarities between the cultures.

> *The other group are Malays so then cultural wise, it's quite different. I think to understand each other's cultural difference… that was helpful* [K3, Female peer volunteer]

Impactful Teaching and Facilitation

Dedicated facilitators consistently worked to build rapport with the older adults, helping to ease initial discomfort and encouraging open communication. Older adults highlighted that the facilitators were highly knowledgeable in their respective fields. They were committed to sharing their knowledge on various topics such as handling difficult situations and mindfulness, which made the older adults feel comfortable asking questions whenever they had any doubts. With that, this fostered communication and the older adults were able to maximize the knowledge gained throughout this PFA program.

> *Think the way they [facilitators] present and they deliver the topic well, yeah and they are very knowledgeable on the topic… you feel motivated.* [K11, Female peer volunteer]

Additionally, many older adults highlighted that they were inspired by the facilitators' presentation style. The facilitators' consistent engagement, well-paced sessions, body language, tone, and delivery made the learning process more accessible and understandable for older learners. The older adults also valued the facilitators' sharing of personal experiences, as it allowed them to learn from real-life situations.

> *I learn from it and [blinded] because she's a mindfulness teacher and I'm learning to teach mindfulness. So of course I also want to learn all the right things from her.* [K3, Female peer volunteer]

Experiential and Applied Learning

Many older adults favored experiential learning over traditional lecture-style delivery. During the PFA program, they were able to actively participate in hands-on activities such as role-plays and this helped them to better visualize and retain the concepts taught.

> *The role play, it showed you like reality what could happen or what will happen or what can happen. That was really like an experience, very good because learning from slides and all is quite normal.* [K1, Female peer volunteer]

Additionally, participants reported that the role-playing exercises played a crucial role in boosting their confidence in handling real-life situations. By simulating real-world scenarios, they were able to "experience" these situations in a controlled environment. This allowed them to observe nonverbal cues and body language, which heightened their awareness of their own nonverbal communication when offering support. The interactive nature of the role-playing activities also facilitated communication among the older adults, helping to break the ice and foster connections.

> *When you have a role play, you really understand it more. You sometimes put yourself into that shoes and see how it is like.* [K1, Female peer volunteer]

Theme 3: Recommendations for Designing Inclusive, Holistic Training Programs

Overview

This theme highlighted recommendations to enhance the PFA program by addressing the varied needs, backgrounds, abilities, and learning styles of the participants. This theme is supported by 2 subthemes as follows: depth and quality of learning, and future learning opportunities.

Depth and Quality of Learning

A few older adults expressed that the content covered was too brief. They desired more in-depth knowledge to be taught, enabling them to gain additional insights that could be applied throughout their volunteerism journey. However, they noted that the brief content might be a result of the short session duration. Therefore, they expressed a preference for longer sessions.

> *I think it can go a bit deeper. It's just that the depth can be, in my personal opinion, if time allowed, the depth can be more* [K9, Female peer volunteer]

Furthermore, the older adults highlighted that the program venue was inconvenient. Some had to get up as early as 7 in the morning to arrive on time for the session. Despite the travel challenges, they expressed a desire for longer sessions to facilitate deeper learning.

> *I find it's really short because we [travel] from the east [and] we spend only two hours… the timing is not enough to share with us.* [K04, Female Peer Volunteer]

Many older adults envisage more hands-on practice during the PFA program. Though older adults caught up during breaks and role-plays, having a specific time for small-group discussions regularly was highlighted by some older adults.

> *I was thinking maybe it's good to have maybe small group discussion during each session.* [K11, Female peer volunteer]

A few older adults suggested incorporating various learning tools, such as case studies and better audio-visual materials for learning. Those older adults with less volunteer experience felt

the need for more case studies to be discussed so that they are more prepared to handle the situations in real life.

> *The other techniques like case study so examples of how we can approach the people… I never counsel anyone so I wouldn't know, what [is] the real situation outside... I am bit worried to handle if someone suddenly cry…* [K3, Female peer volunteer]

In addition, older adults highlighted several considerations that influenced their learning experience when engaging with older learners. They encountered issues with audio and visual clarity, such as some participants finding the projected fonts too small, requiring them to squint to read. Furthermore, the facilitators' lack of use of a microphone led to poor hearing, making it difficult for a few participants to fully comprehend the content taught.

> *As we age, our eyesight is not so good, we have to strain our eyes. I had to strain my eyes to read [the slides].* [K1, Female peer volunteer]

> *If you're seated behind far away, you can't hear much. I'm trying to figure out what he's saying. So if you have a mic, then at least, you know, we can hear, everybody can hear.* [K4, Female peer volunteer]

Future Learning Opportunities

Older adults highlighted the potential for future learning opportunities. Many expressed a desire for regular "top-up" sessions, either annually or semiannually, to revise the knowledge. Furthermore, they showed interest in gaining new knowledge through these regular sessions. A few older adults stressed the importance of regular sessions so that more peer volunteers from their respective organizations could participate and benefit from the PFA program.

> *It will be good if there's every six months or a year, we come back do skill upgrading.* [K9, Male peer volunteer]

> *I think we need to have more of this courses, for more people to be trained because now Singapore is aging.* [K7, Male peer volunteer]

In addition, they valued the regular sessions as an opportunity to reconnect with their peers. They were eager to meet and share their recent volunteerism experiences, fostering mutual learning through casual conversations.

> *A small group, then we will have regular meetups for sharing and to also impart certain message.* [K11, Female peer volunteer]

Discussion

Principal Findings

This study explored the experiences of peer volunteers in the PFA program in Singapore, providing insights into their motivations, challenges, and the overall impact of their participation. All interviewed peer volunteers participated in all 4 sessions of the program. The sample was primarily composed of Malay participants (n=6), followed by Chinese participants (n=5), with one participant from each of the Indian and Javanese communities. While Singapore's population is predominantly Chinese, Malay, and Indian, future studies could aim for a more balanced racial distribution to better reflect broader societal trends [39].

The older adults in this study cited various reasons for their continued involvement in volunteerism, including cultural values instilled by their families, peer influence, and the promotion of healthy aging. Through volunteerism, the older adults in this study were also able to actively engage with the community, fostering new friendships and a sense of purpose. This aligns with existing literature, with studies conducted in Japan, Australia, and the United Kingdom suggesting that the motivations for volunteerism in older adulthood were driven by community engagement, building new friendships, positive influences on personal well-being, and the desire to foster a sense of purpose [40-42]. Interestingly, altruistic attitudes, such as cultural values of graciousness instilled in them, were a key motivation for the older adults in our study. This contrasts with existing literature, where volunteers report motivations driven by egoistic reasons such as the development of a new skill and personal satisfaction [43,44]. This difference may be attributed to the strong Asian values that emphasize family cohesion and collective well-being [45]. As such, future studies can compare and explore volunteer motivations across different cultural contexts.

While the older adults in this study demonstrated a strong commitment to volunteerism, they also faced personal barriers, including difficulties in engaging with the community and physical limitations such as ongoing medical conditions or frailty. Chronic illnesses or frailty restrict their ability to participate in physically demanding tasks, limiting their ability to contribute as fully as they may have wished. This is consistent with studies conducted on older adults in Spain and Norway, which found that maintaining good health was a key factor enabling volunteerism as it was highly prioritized by older adults [46,47]. These challenges highlight the need for support systems that prioritize older adults' health to ensure their ongoing participation in volunteer activities, ultimately improving both their physical well-being and their ability to contribute meaningfully to the community.

Cultural and social sensitivity emerged as another key theme in this study. Older adults encountered cultural taboos, particularly within the Muslim community, where there was a preference for interactions within one's own ethnic or social circle. This limited broader community engagement, highlighting the importance of cultural sensitivity in volunteer programs. Additionally, gender dynamics were cited as a challenge, with female participants feeling more comfortable providing support to those of the same gender. These findings are consistent with research indicating that cultural and gender factors can influence interpersonal dynamics in volunteer settings [48]. This may be attributed to Singapore's diverse ethnic composition, where cultural norms are critical. Furthermore, in the Asian context, where gender dynamics are often less openly discussed, it is possible that the older adults in this study feel more at ease interacting with individuals of the same gender [49]. This suggests the importance of addressing these sensitivities in designing inclusive volunteer

programs that accommodate diverse cultural and gender preferences. Future research could explore how these factors shape volunteer experiences and inform the development of more culturally inclusive training programs.

Personal development emerged as another significant theme, with participants noting the value of peer interactions, role-plays, and experiential learning during the PFA program. These activities not only reinforced the content but also helped participants apply the concepts to real-world situations. This contrasts with a study of clinicians in the United States, where participants expressed a preference against interactive training methods [50]. The difference may be attributed to the older adult population's preference for active, hands-on learning approaches, which has been noted in other studies [51]. Facilitators also played a crucial role, providing reassurance and fostering a supportive learning environment. This finding is consistent with research indicating that facilitators' knowledge and support are integral to positive learning experiences [52,53]. Participants in this study also expressed a desire for more knowledge and confidence to handle real-life situations, aligning with findings from Japan and Haiti, where peer volunteer training boosted confidence in applying training strategies safely [54,55]. This highlights the importance of designing volunteer training programs that incorporate both theoretical knowledge and practical, experiential learning.

Designing inclusive training programs involves a holistic approach that considers accessibility, logistical support, practical learning experiences, and efficient course delivery, all of which contribute to enriched learning experiences and future improvement opportunities. Our study highlighted that the participants in our study desired greater comprehensive coverage of the content, with additional hands-on practice and small group discussions to enhance the training experience and add greater value to their volunteerism journey. Additionally, they expressed interest in incorporating other educational tools, such as case studies, to better assimilate real-world scenarios and mentally prepare themselves. This is consistent with studies conducted in Gaza, Korea, and Singapore, which emphasized that PFA trainers desire more in-depth training and new delivery approaches to psychologically equip themselves, enabling them to better support the recipients [25,52,56]. Additionally, older adults in our study emphasized the importance of regular sessions to stay informed about current information about PFA. Moreover, our study found that holding regular sessions would facilitate enrollment for prospective participants, providing them with comprehensive knowledge. These findings align with studies conducted in the United States and the United Kingdom, where participants envisage refresher sessions for PFA to further equip themselves with the latest knowledge [32,50]. Furthermore, several participants in our study, drawing on their prior volunteerism experience, expressed a desire for advanced volunteerism courses offering enhanced learning opportunities. This aligns with findings from studies conducted in the United States and Singapore, which highlight that individuals with volunteerism experience gain greater benefits from comprehensive training programs compared with basic ones [50,52]. Thus, a holistic approach to program design, which considers accessibility, practical learning opportunities, and continuous support, can enhance the overall success and impact of volunteer programs, and stakeholders can consider these recommendations in providing better support to the peer volunteers and, in turn, to the community-dwelling older adults.

Limitations

This study has a few limitations. First, this study was conducted on English-speaking older adults and may not be transferable to non–English-speaking older adults in Singapore. Furthermore, Indians were underrepresented in this study. Hence, future studies can consider exploring the purposive sampling technique to study participants who are non–English-speaking and from diverse ethnic backgrounds to get a holistic understanding of the phenomenon of interest. Second, interviews were conducted with a convenience sample of older adults who volunteered to participate and hence could have harbored particularly positive views from those participants who were motivated to share about the PFA program. Third, a potential limitation is that participants were not explicitly asked to provide feedback on the interview guide during the pilot interviews, specifically on aspects such as question clarity, sequencing, and overall structure. Such feedback could have offered valuable insights for refining the guide and enhancing its suitability. This should be considered in future research.

Implications for Future Research and Practice

Future research should explore the influence of cultural norms and gender dynamics in volunteer programs, particularly in diverse and multiethnic contexts like Singapore. Studies can investigate how cultural and gender considerations affect volunteer engagement and explore strategies for overcoming these barriers. Future studies should focus on the role of cultural sensitivity training and its impact on improving interactions among volunteers and community members. The physical limitations of older adults, including chronic illnesses or frailty, were identified as significant barriers to volunteerism. Future research should delve deeper into how health status influences volunteer participation and explore ways to accommodate volunteers with varying levels of physical ability. Moreover, longitudinal studies could assess the long-term health benefits of volunteerism and how these programs might mitigate the physical limitations of older adults. Stakeholders working with older adults, such as community partners and health care providers, could benefit from considering the cultural and age-related concerns highlighted in this study. Understanding the unique cultural values, gender dynamics, and health challenges faced by older adults is crucial for fostering more effective engagement and providing tailored support. This study highlighted the importance of hands-on learning, role-playing, and peer interactions in enhancing volunteers' understanding and confidence. Future research should focus on evaluating the effectiveness of different interactive learning methods across various populations. Additionally, exploring the impact of peer-led sessions versus professional-led training could help refine approaches to fostering confidence and competency in volunteers. Research into the most effective formats for delivering such programs—whether through in-person, via web, or hybrid methods—could contribute valuable knowledge to improve volunteer retention and engagement. This study

emphasizes that individuals with prior volunteerism experience benefit from a more comprehensive training curriculum. Hence, future research can explore the potential of offering both basic and advanced PFA programs for learners at different proficiency levels to enhance individual learning outcomes. While this study focused on short-term engagement with the PFA program, future research should explore the long-term effects of participation on older adults' well-being, volunteer retention, and community impact.

Conclusions

This study explored the experiences of older adult volunteers who participated in a PFA program in Singapore. Findings highlighted the complex interplay of cultural, social, and personal factors that influence the experiences of older adult volunteers. The findings suggest that training programs could be designed with cultural sensitivity, provide experiential learning opportunities, and support participants' ongoing personal development to maximize their engagement and impact. Future research should further explore these findings to develop more inclusive, effective, and sustainable volunteer programs that empower older adults to contribute meaningfully to their communities.

Abstract

Background: Electronic personal health records (ePHRs) hold significant potential to improve health management for older adults by enhancing access to medical information and facilitating communication with health care providers. However, usage remains low among individuals aged 65 and older. While existing research has identified barriers such as low self-efficacy, limited digital literacy, and usability challenges, the specific factors influencing the use of ePHRs among older adults are not yet fully understood.

Objective: This study integrates the Aging and Technology framework with the Patient Technology Acceptance Model to examine key predictors of ePHR use among older adults, including age, education, issue involvement, performance expectancy, effort expectancy, and self-efficacy, while controlling for demographic factors such as gender, race, and income.

Methods: This study utilizes data from the Health Information National Trends Survey (HINTS 5 cycle 3), which includes 532 respondents representing 13,136,180 US adults aged 65 years and older, after applying survey weights. Structural equation modeling was used to analyze the factors influencing the frequency of ePHR access over the past 12 months.

Results: The findings indicate that older adults with higher self-efficacy used ePHRs more frequently. Additionally, issue involvement, performance expectancy, and effort expectancy were positively associated with ePHR use. Notably, self-efficacy partially mediated the relationship between age and the frequency of ePHR use.

Conclusions: These findings suggest that enhancing self-efficacy, improving usability, and increasing the perceived benefits of ePHRs are critical for boosting usage among older adults. The study underscores the need for targeted interventions to support older users, simplify digital interfaces, and provide accessible educational resources, ultimately contributing to better health outcomes and an improved quality of life for older adults.

Introduction

Background

Health information technologies (HITs), such as electronic health records (EHRs) and electronic medical records (EMRs), are pivotal tools in modernizing health care by enhancing efficiency and improving the quality of care [1-3]. Beyond these general applications, HIT has the potential to address the unique medical needs of the older population. Extensive research demonstrates that HIT use can significantly improve health outcomes for older adults [4], particularly through tools such as EMRs and electronic personal health records (ePHRs). For example, EMRs in hospital settings help health care professionals identify at-risk patients, such as those prone to falls, by analyzing factors such as age and medication use [5]. Similarly, ePHRs empower older adults by providing easier access to health information, fostering improved communication with health care providers, and encouraging active engagement in personal health care management [6].

Luo et al [7] highlighted that, among older adults, the use of ePHRs was positively associated with the ease of understanding health information. ePHRs enable patients to track their health history to better understand the progress or deterioration of their health conditions. Patients with access to their health information experience increased medical data transparency, which reduces medical errors, improves trust in care providers, and enhances

patient satisfaction [8]. As such, in the United States, the adoption of ePHRs has steadily increased. This growth has been supported by policies such as the Health Information Technology for Economic and Clinical Health Act of 2009 [9], which incentivized health care providers to adopt EHR systems through financial rewards, indirectly creating an infrastructure supportive of ePHRs. The subsequent Meaningful Use Program set specific objectives for health care providers to demonstrate effective use of EHRs, including patient-access capabilities. Further support came from the 21st Century Cures Act of 2016 [10], which enhanced patient access to electronic health information and prohibited information blocking, thereby facilitating smoother integration and utilization of ePHRs.

While the benefits of HIT for older persons are well-documented, the adoption and sustained use of these technologies face notable barriers, such as lower levels of technology usage among older adults [11]. Recent data indicate that approximately 4 in 10 individuals aged 65 years and older utilize ePHRs, a rate significantly lower than that of younger populations [12]. Furthermore, a previous study reported that approximately 54% of US adults have been offered access to their online medical records, and among those offered, 57% accessed them at least once, translating to about 31% of the adult population accessing their online medical records [13]. However, specific statistics for individuals aged 65 years and older are not provided in this source. Given that older adults are generally less likely to use the internet, it is reasonable to infer that their rates of ePHR usage may be lower than those of younger populations [12].

Further, researchers have found that older age is negatively associated with HIT [14]. Reduced cognitive and motor abilities, common among older adults, often complicate interactions with modern digital applications [15,16]. van der Vaart et al [8] discussed how older age is associated with the nonuse of web-based portals. Czaja and Lee [17] argued that although older adults are willing to use technology, many report usability problems with existing systems, which may, in part, be due to the cognitive and perceptual demands placed on the user. Their findings show that self-efficacy is an important predictor of general use of technology and that people with lower self-efficacy are less likely to use technology. However, individual-level barriers such as confidence and usability are only part of the picture. A growing body of research suggests that technologies are often not designed with the specific needs of older adults in mind [18,19]. Studies have also shown that older patients may not be offered digital health tools for various reasons, including—but not limited to—age-related stereotypes held by health care professionals or concerns about overburdening older patients [20,21]. Together, these individual and environmental barriers create a complex landscape that can inhibit older adults' use of health technologies.

Despite advancements in technology, significant gaps remain in understanding the factors that influence the regular use of ePHRs among older adults. Existing research has focused on general barriers and facilitators, but limited knowledge exists about the interplay between these factors and how they shape the frequency of ePHR usage. This knowledge gap calls for a deeper examination of the factors affecting ePHR use in older populations. Additionally, limited electronic health literacy remains a critical challenge that hinders ePHR use in older populations [22]. However, the potential benefits cannot be overlooked. ePHRs offer older adults opportunities to coordinate their health care by sharing critical health information with providers and other stakeholders, an approach particularly crucial for managing chronic conditions that require multifaceted treatment strategies [7].

There are still unanswered questions about how older adults use ePHRs, particularly regarding the specific factors that facilitate or hinder ePHR use and the extent to which these factors influence it. To address this gap, this study explores the following research questions:

- What are the key factors influencing the use of ePHRs among older adults?
- How do age and education mediate the impact of self-efficacy on the frequency of ePHR use in older populations?
- What roles do facilitators such as issue involvement, performance expectancy, and effort expectancy of ePHRs play in encouraging regular use?

To answer these questions, we build on established theoretical frameworks such as the Patient Technology Acceptance Model (PTAM) [23], which provides insights into technology adoption and use processes. We extend the PTAM by incorporating factors specifically relevant to older persons, such as usability challenges, limited education, and issue involvement, to develop a comprehensive understanding of the dynamics at play. This study aims to contribute to the literature by offering empirical evidence and actionable insights into how ePHRs can be effectively designed and implemented to support the unique health care needs of aging populations.

Hypotheses and Proposed Model

Overview

This study aims to deepen the understanding of the frequency of PHR use among the older population by addressing critical individual factors that influence usage. A nuanced understanding of these factors is essential for improving ePHR-related outcomes, such as patient empowerment, health care accessibility, and overall health management. Specifically, this research investigates the determinants influencing the frequency of ePHR use among individuals aged 65 years and older.

Based on the existing literature, we contend that theoretical frameworks grounded in the Technology Acceptance Model (TAM) [24], including the PTAM [23], are particularly suitable for investigating frequency of use, aligning well with our study's specific outcomes. Previous research applying the TAM has effectively examined ongoing usage rather than merely initial adoption. For instance, McCloskey [25] utilized the TAM to evaluate sustained electronic commerce (e-commerce) behaviors, specifically the frequency of online purchasing, and found that perceived usefulness directly influenced the frequency of technology use. Similarly, Lederer et al [26] applied the TAM to explore frequent usage of the World Wide Web, explicitly addressing ongoing use rather than initial acceptance. Moreover, Martín-García et al [27] extended the TAM framework to

examine older adults' frequency of using technological devices, demonstrating the applicability of TAM constructs beyond initial intentions to sustained technological engagement.

Building upon this foundation, we integrate Czaja et al's [28] conceptual model of aging and technology with the PTAM [23]. Our selection of the PTAM specifically addresses our research context—older patients managing multiple chronic conditions at home using digital health tools. Unlike broader acceptance models such as the TAM [24], the Unified Theory of Acceptance and Use of Technology (UTAUT) [29], and the Health Belief Model [30], PTAM explicitly considers patient-centric variables critical for older populations managing complex health conditions.

For example, while the TAM broadly emphasizes general technological acceptance through perceived ease of use and perceived usefulness, it lacks explicit patient-oriented or health outcome considerations [31]. Similarly, the UTAUT primarily addresses technology acceptance within general workplace contexts rather than the nuanced health care needs of older patients with chronic conditions [32]. The Health Belief Model likewise falls short by inadequately addressing the interactive dynamics unique to older patient populations [33].

By contrast, PTAM's incorporation of patient-specific constructs—such as perceived health improvements, patient-provider relationships, and health care contextual factors—offers a more precise and comprehensive understanding of older patients' sustained engagement with digital health interventions. This tailored approach provides richer theoretical insights and clearer practical implications, significantly enhancing explanatory power and applicability compared with general acceptance models.

Age

The utilization of ePHRs and patient portals exhibits notable age-related disparities. Despite being frequent consumers of health care services, older adults are significantly less likely to use these digital tools compared with younger individuals [34]. This gap in use can be attributed to age-related barriers, such as limited digital literacy and difficulties in navigating technological interfaces, which become increasingly pronounced with age [34,35].

A systematic review of patient acceptance of HIT underscored this trend, finding a negative correlation between age and HIT acceptance [14]. Similarly, Heart and Kalderon [36] provided compelling evidence that older adults demonstrate lower use of health-related information and communication technologies. Additionally, van der Vaart et al [8] highlighted that older individuals are generally less likely to use patient web portals. Based on these findings, we propose the following hypothesis:

- *H1a: Age is negatively associated with the frequency of ePHR use.*

Research has consistently shown that as individuals age, their electronic self-efficacy—the belief in their ability to effectively use technology—tends to decline. This decrease in self-efficacy is often attributed to a combination of factors, including reduced exposure to new technologies, cognitive decline, and negative stereotypes associated with older adults and technology use. For example, studies suggest that older adults are more likely to perceive technology as complex and overwhelming, which can lower their confidence in using digital tools such as EMRs or patient portals [28]. With age, physiological capacity and the ability to respond to environmental stresses decline, further contributing to the reduction in electronic self-efficacy [37]. Hence, we hypothesize:

- *H1b: Age is negatively associated with self-efficacy.*

Education

Smith et al [38] argued that individuals with higher levels of education are more likely to register for and utilize patient portals. Empirical evidence supports this claim, indicating that higher educational attainment is positively correlated with increased patient portal usage [39]. Educated individuals are more likely to engage with digital platforms for managing their health information, as they typically possess greater health literacy and familiarity with technology. Furthermore, a recent literature review highlights that lower educational levels act as a barrier to ePHR use [40]. Similarly, individuals with higher education are more likely to perceive the benefits of ePHRs, leading to higher usage rates [41]. Based on these findings, we propose the following hypothesis:

- *H2a: Education is positively associated with the frequency of ePHR use*.

Research consistently demonstrates that education and training play a pivotal role in enhancing individuals' electronic self-efficacy, particularly in the context of using digital tools such as patient portals and EMRs. Czaja et al [28] highlighted a positive association between education and self-efficacy, emphasizing the importance of foundational skills acquired through educational experiences. These skills, including problem-solving, critical thinking, and basic computer literacy, are critical for successfully navigating digital platforms [42]. Furthermore, education has been shown to empower individuals across all age groups to overcome barriers to technology use. Based on this, we propose the following hypothesis:

- *H2b: Education is positively associated with self-efficacy.*

Issue Involvement

Issue involvement in the health care domain refers to "how relevant a specific health issue is to a patient" [43,44]. A more involved patient typically has a severe health condition and frequently visits health care providers [45]. Ross et al [46] argued that issue involvement has a significant positive impact on the use of patient-accessible medical records. This finding is further confirmed by Angst and Agarwal [45] and Abdelhamid et al [43]. A more involved patient is more likely to use ePHRs, as they help patients better prepare for upcoming visits with physicians by enhancing their knowledge of their medical condition, increasing their sense of control, and allowing them to seek clarification about treatment. Hence, we hypothesize:

- *H3: Issue involvement is positively associated with the frequency of ePHR use.*

Performance Expectancy

Performance expectancy is defined as the degree to which a person feels that using a system will help them perform a job more efficiently [29]. In keeping with this understanding, we refer to performance expectancy as the degree to which the patient believes that using ePHRs helps them monitor their health. Venkatesh et al [29] theorized that performance expectancy drives the intention to use information systems. Several researchers have also identified performance expectancy as one of the critical predictors of eHealth acceptance and use [40,47-49]. Patient portals help improve patient engagement and empower individuals to access their health information anytime and anywhere [50]. Thus, we hypothesize:

- *H4: Performance expectancy is positively associated with the frequency of ePHR use.*

Effort Expectancy

Venkatesh et al [29] defined effort expectancy as the degree of comfort associated with system use. Consistent with Venkatesh et al [29], we define effort expectancy as the degree of ease associated with understanding the health information in the online medical record. Effort expectancy is another key variable that drives use intentions [46]. Many researchers have also identified effort expectancy as one of the critical predictors of health technology use [2,23,37,48]. Therefore, we also propose the following hypothesis:

- *H5: Effort expectancy is positively associated with the frequency of ePHR use.*

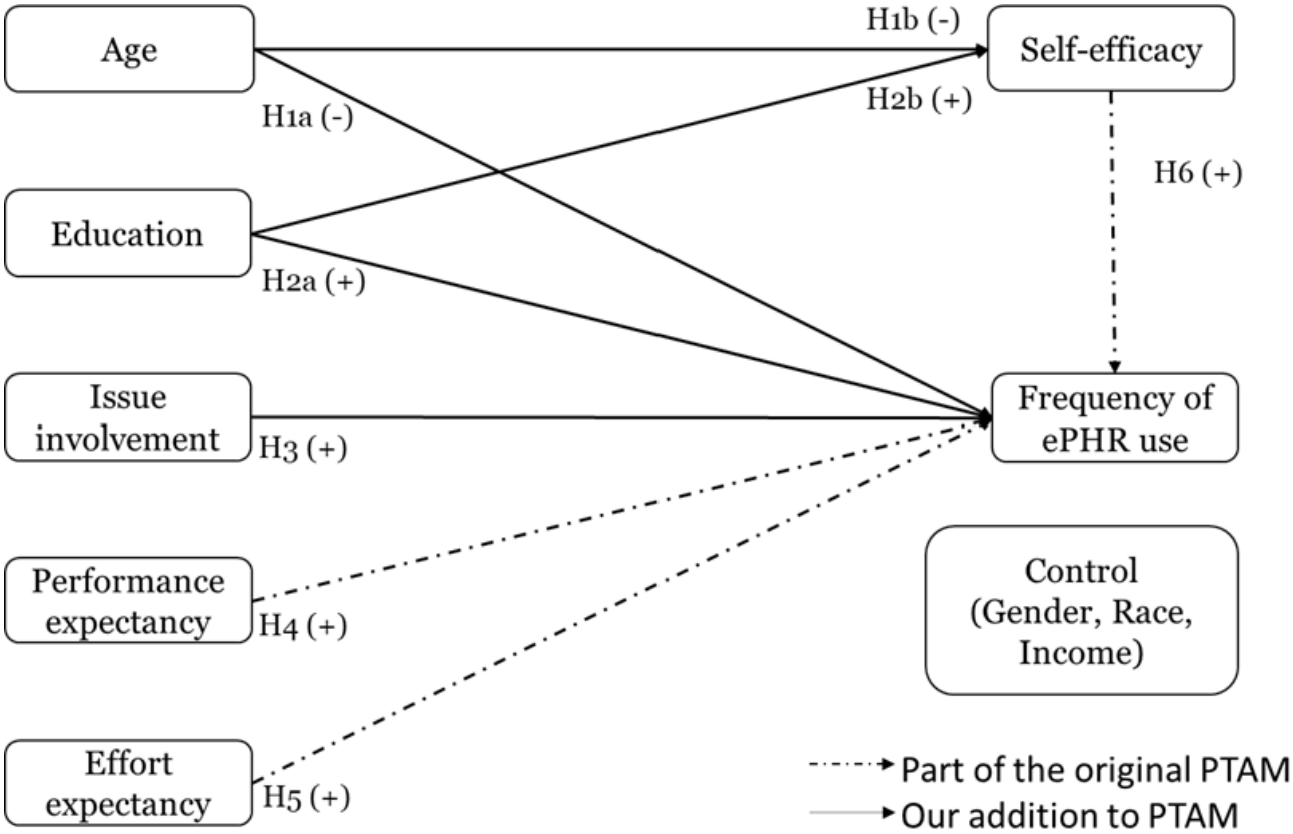
Self-Efficacy

Research has consistently demonstrated that electronic self-efficacy—the belief in one's capability to effectively use technology—declines with age due to factors such as reduced exposure to new technologies, cognitive decline, diminished physiological capacity, and negative stereotypes about older adults' technology use [28,37]. Consequently, older adults often perceive technology, including ePHRs, as complex and overwhelming, undermining their confidence in engaging with such digital tools. Therefore, we selected self-efficacy as a mediator to explicitly capture the psychological mechanism linking age with ePHR use. Rather than age directly limiting ePHR engagement, we posit that reduced electronic self-efficacy partially explains why older adults use ePHRs less frequently. This approach emphasizes the central role of self-efficacy in technology use among aging populations [36,51]. Hence, we hypothesize:

- *H6: Self-efficacy is positively associated with the frequency of ePHR use.*

Our proposed model is depicted in Figure 1. Additionally, we control for demographic factors such as gender, race, and income to account for their potential influence on the frequency of ePHR use.

Figure 1. The research model. ePHR: electronic personal health record; PTAM: Patient Technology Acceptance Model.



Methods

Data Source

This study used publicly available cross-sectional data collected in 2019 by the National Cancer Institute (Health Information National Trends Survey [HINTS] 5 cycle 3). The cross-sectional analysis for this study was limited to a subset of the original dataset and included participants aged 65 years or older. The total number of individuals aged 65 years or older was 1961. Of these, 1234 had not used an ePHR at least once in the past 12 months and were therefore excluded from the analysis. Further, 195 responses were removed due to missing values for key variables. The final sample consisted of 532 respondents, representing 13,136,180 US adults aged 65 and older when survey weights were applied.

Ethical Considerations

The HINTS 5 survey, conducted with the general population, underwent expedited review and received approval from the Westat Institutional Review Board on March 28, 2016 (project number 6048.14). This analysis used deidentified, publicly available data from HINTS, which did not constitute human research as defined by 45 CFR 46.102 and, therefore, did not require Institutional Review Board review.

Measurements

In this study, the primary dependent variable, “frequency of ePHR use,” is operationalized using a single-item measure assessing how frequently patients accessed their online medical records within the past 12 months. The response options are categorized as follows: 1-2 times, 3-5 times, 6-9 times, and 10 or more times. Individuals who reported not accessing their online medical records during the past year were excluded from the analysis, as critical variables pertinent to these respondents were not captured.

Performance expectancy, representing the perceived usefulness of online medical records for health monitoring, is measured using a 5-point Likert scale, ranging from “5=very useful” to “1=don’t use.” Effort expectancy, reflecting the perceived effort necessary to understand health information in online medical records, is assessed using a 4-point Likert scale ranging from “4=very easy” to “1=very difficult.” Issue involvement captures an individual’s engagement with personal health management and is operationalized as the number of interactions a respondent has had with health care providers over the past year. Self-efficacy in accessing electronic health records is assessed through a binary-choice question indicating whether respondents have utilized any electronic method to access their medical records during the past 12 months.

Single-item measures are used for several constructs in this study. Such measures are considered acceptable when questions are clear, unambiguous, and not prone to multiple interpretations [52]. Additionally, single-item measures are prevalent and widely validated within information systems research, particularly in studies applying structural equation modeling (SEM) in health care contexts [43,44].

Gender, race, and income are incorporated as control variables, consistent with prior studies [43,44]. For comprehensive details on questionnaire items, scales, and specific variable operationalizations, please refer to Multimedia Appendix 1.

Statistical Analysis

This study uses SEM to conduct a path analysis. Although SEM is predominantly used to model latent variables, it is also commonly applied to conduct a path analysis in mediation models. We examine 2 mediating relationships: first, self-efficacy mediates the relationship between age and the frequency of ePHR use; second, self-efficacy also mediates the relationship between education and the frequency of ePHR use. Accordingly, we use SEM to test the model, consistent with prior research [53,54]. We used SEM with weighted least squares mean and variance adjusted estimation to test the hypotheses. Weighted least squares mean and variance adjusted is well-suited for models with ordinal outcome variables [55,56]. The analysis was conducted in R (R Foundation) using the “lavaan.survey” package. We incorporated HINTS-supplied survey weights and used jackknife variance estimation techniques to account for the complex HINTS sampling design and to calculate nationally representative estimates [57].

Results

Descriptive Statistics

Table 1 shows the descriptive statistics of the survey respondents. The survey included questions about the frequency of participants’ ePHR use, as well as questions related to the model variables, including performance expectancy, effort expectancy, issue involvement, self-efficacy, age, education, gender, race, and income.

Table . Descriptive statistics.

Demographic characteristics	Sample size (N=532)[a]	With survey weights (N=13,136,180)[b]
Gender		
Male	249 (46.8)	5,729,371
Female	283 (53.2)	7,406,809
Race		
White	458 (86.1)	11,961,412
Non-White	74 (13.9)	1,174,768
Education		
Less than high school	7 (1.3)	278,445
High school or higher	525 (98.7)	12,857,735
Income (US $)		
Less than 20,000	57 (10.7)	1,191,896
20,000 to <35,000	68 (12.8)	2,009,787
35,000 to <50,000	86 (16.2)	2,100,148
50,000 to <75,000	122 (22.9)	3,110,545
75,000 or higher	199 (37.4)	4,723,804
Age (years)		
Range	65-97	65-97
Mean (SD)	71.68 (5.66)	71.90 (6.09)

[a]The sample size for gender, race, education, and income is presented as n (%).

[b]Data are presented as n for gender, race, education, and income.

Reliability and Validity

Table 2 presents the correlations between all variables of interest. Correlation coefficients are important because high correlations among independent variables may indicate multicollinearity, which can introduce bias into the model results. Multicollinearity is not a concern in this analysis, as all correlations fall within the acceptable threshold of 0.6 [58], with the highest correlation being 0.37 between performance expectancy and effort expectancy. Table 2 also provides the means and SDs for the principal variables.

Table . Correlation matrix.

Correlation	Mean (SD)	Performance expectancy	Effort expectancy	Issue involvement	Self-efficacy
Performance expectancy	4.15 (1.03867)	1.00	—[a]	—	—
Effort expectancy	3.30 (0.67763)	0.37	1.00	—	—
Issue involvement	3.80 (1.49733)	−0.01	−0.14	1.00	—
Self-efficacy	0.82 (0.38126)	0.17	0.06	0.09	1.00

[a]Not applicable.

Common Method Variance

As data are self-reported and collected through a single survey, they may suffer from common method variance (CMV), which hampers the relationship between the variables [59]. We used the marker variable technique [60] to check if the data are suffering from CMV. Marker variable is a variable that is theoretically unrelated to 1 or more of the principal variables measured in the study and typically has a low correlation with the central variables.

The theoretically unrelated construct “morning person or night person” was used as a marker variable. The correlations between the marker variable morning person or night person and other principal variables were below the threshold of 0.1 (performance expectancy: −0.08; effort expectancy: −0.08; self-efficacy: 0.03) [60], except for issue involvement (0.17). The low correlation of the marker variable with the principal variables in the model indicates that CMV is not a problem.

Data Analysis

As the National Cancer Institute administered both a paper-based questionnaire and an online questionnaire to survey participants, we first assessed whether the mode of survey introduced any biases. We regressed the dependent variable, "frequency of ePHR use," on the mode of survey and found that the relationship between the 2 was nonsignificant (*P*=.48). Thus, the mode of survey administration did not introduce any bias in the main outcome variable, that is, "frequency of ePHR use."

The SEM results are presented in Table 3. The overall fit statistics (χ^2_{17}=13.230, *P*=.004; Comparative Fit Index=0.950, Tucker-Lewis Index=0.715, root-mean-square error of approximation=0.080, standardized root-mean-square residual=0.022) indicate a good model fit [61]. Table 4 presents the results of the mediation analysis for self-efficacy with age and education.

The results show that age is negatively associated with self-efficacy (β=−.9890, *P*=.03), suggesting that as age increases, self-efficacy decreases, supporting H1b. However, no significant (*P*=.85) relationship was found between self-efficacy and education (H2b) in our research context.

Further, the results show that age is positively associated with the frequency of ePHR use (β=1.4950, *P*=.03), suggesting that as age increases, ePHR use also increases. This is the opposite of what we hypothesized for H1a. This counterintuitive trend may reflect increased health care needs among older adults, leading to greater engagement with ePHRs for managing chronic conditions, medication schedules, and communication with physicians. No significant (*P*=.88) relationship was found between education and the frequency of ePHR use (H2a) in our research context. H3 proposed a positive relationship between issue involvement and the frequency of ePHR use. The path coefficient was positive and statistically significant (β=.2560, *P*<.001), suggesting that higher issue involvement leads to higher ePHR use.

Our analysis also revealed a significant positive relationship between performance expectancy and the frequency of ePHR use (β=.2470, *P*<.001), as well as between effort expectancy and the frequency of ePHR use (β=.1850, *P*=.04). These findings suggest that higher performance expectancy and higher effort expectancy both lead to increased ePHR use, supporting H4 and H5. We also found that self-efficacy is positively associated with the frequency of ePHR use (β=.4990, *P*<.001), supporting H6.

Further analysis confirms that self-efficacy partially mediates the relationship between age and the frequency of ePHR use among older adults, as evidenced by the statistical significance of both indirect (*P*=.03) and direct effects (*P*=.03). Specifically, self-efficacy accounts for 49.2% (−0.493/1.002) of the total effect, underscoring its substantial role as a mediator in this relationship. However, we did not find any statistically significant mediating effect of self-efficacy on the relationship between education and the frequency of ePHR use.

Table . Results of structural equation modeling.

Dependent variable and hypothesis	Variables	Estimate	95% CI	*P* value	Significant
Self-efficacy					
H1b	Log (age)	−0.9890	−1.8870 to −0.0900	.03	Yes
H2b	High school or more	−0.0360	−0.4070 to 0.3350	.85	No
Control	Female	−0.0190	−0.1300 to 0.0910	.73	No
Control	White	−0.0040	−0.1460 to 0.1370	.95	No
Control	Income	0.0120	−0.0200 to 0.0430	.47	No
Dependent variable: frequency of electronic patient health record use					
H1a	Log (age)	1.4950	0.1460 to 2.8440	.03	Yes
H2a	High school or more	0.0320	−0.3770 to 0.4410	.88	No
H3	Issue involvement	0.2560	0.1810 to 0.3300	<.001	Yes
H4	Performance expectancy	0.2470	0.1340 to 0.3600	<.001	Yes
H5	Effort expectancy	0.1850	0.0070 to 0.3640	.04	Yes
H6	Self-efficacy	0.4990	0.3260 to 0.6730	<.001	Yes
Control	Female	0.1970	−0.0410 to 0.4340	.10	No
Control	White	0.0590	−0.3050 to 0.4220	.75	No
Control	Income	−0.0300	−0.1290 to 0.0680	.54	No

Table . Mediation results of structural equation modeling.

Variables	Estimate	95% CI	*P* value	Significant
Log (age)				
Indirect through self-efficacy	−0.4930	−0.9410 to −0.0460	.03	Yes
Direct	1.4950	0.1460 to 2.8440	.03	Yes
Total	1.0020	−0.3170 to 2.3200	.14	No
High school or more				
Indirect through self-efficacy	−0.0180	−0.2040 to 0.1680	.85	No
Direct	0.0320	−0.3770 to 0.4410	.88	No
Total	0.0140	−0.4860 to 0.5140	.96	No

Discussion

Determinants of ePHR Use

Our study aimed to update the PTAM by examining the impact of performance expectancy, effort expectancy, and self-efficacy on the frequency of ePHR Use. By using an integrated framework, this research provides actionable insights into the factors driving ePHR usage among older adults, incorporating variables that have not been widely explored in prior studies. This study makes both a significant theoretical and practical contribution.

Theoretical Implications

This study contributes to the literature on ePHR use by building on and extending existing theoretical frameworks, including the Aging and Technology framework [28] and the PTAM [23]. Prior research has predominantly highlighted barriers to ePHR use among older adults, such as reduced self-efficacy, usability challenges, and low digital literacy [15,17]. While these studies provide an important foundation, our findings challenge and refine these perspectives by demonstrating a positive association between age and ePHR use, with self-efficacy serving as a partial mediator in this relationship.

Contrary to earlier work suggesting older age is a barrier to HIT use [8,14], this study reveals that age positively influences ePHR use when health needs increase, as chronic illnesses and frequent health care interactions necessitate greater reliance on digital tools. This finding aligns with studies emphasizing the contextual nature of technology use, where health-related motivations can offset age-related challenges [7]. By demonstrating that older adults use ePHRs more frequently despite lower self-efficacy, this study extends theoretical models by incorporating health-related drivers, such as issue involvement, into the broader narrative of technology adoption.

Self-efficacy, identified as a strong predictor and mediator, validates and expands prior work in the field. Studies have consistently highlighted self-efficacy as a key determinant of technology use [62]. Our findings reinforce this and reveal that self-efficacy mediates the impact of both age and education on ePHR use. This underscores the critical role of psychological factors, particularly in populations facing cognitive and physical challenges, and aligns with theories from the PTAM [23] and the UTAUT [29].

The study also affirms the relevance of performance expectancy and effort expectancy as critical drivers of ePHR usage, consistent with the PTAM and UTAUT frameworks [47,48]. However, by identifying issue involvement as a significant predictor, this study contributes a novel dimension to the literature. This finding supports prior arguments that perceived relevance and personal health involvement significantly enhance engagement with health technologies [43,45].

Overall, this research advances theoretical understanding by integrating psychological, motivational, and contextual factors into established frameworks for HIT use. It bridges gaps in the existing literature by demonstrating that age, when considered alongside mediating factors such as self-efficacy and health involvement, can positively influence ePHR use. These insights offer a nuanced understanding of older adults' interactions with health technologies, offering a robust foundation for future research and practical interventions.

Practical Implications

Overview

The findings of this study underscore several actionable strategies for health care providers, policy makers, and technology developers to enhance ePHR usage among older adults. By addressing barriers and leveraging the facilitators identified, targeted interventions can empower older adults to better manage their health through ePHRs, contributing to improved health outcomes and broader system-wide benefits, as outlined below.

Building Self-Efficacy Through Tailored Training Programs

To enhance older adults' self-efficacy in using ePHRs, health care organizations can establish targeted training and education programs aligned with the recommendations of the Office of the National Coordinator for Health Information Technology [63]. These programs could include workshops in collaboration with senior community centers and local health care providers, focusing on essential tasks such as medication tracking, viewing test results, and scheduling appointments [64]. Additionally, peer-led mentoring initiatives, consistent with community-based

health literacy efforts promoted by Healthy People 2030, can encourage skill sharing among older adults [65].

Supporting Continuous Improvement and User-Centered Innovation

Continuous evaluation through user feedback mechanisms should be institutionalized to guide the ongoing improvement of ePHR technologies [66], particularly for older adults. Actively encouraging the participation of older adults in innovation processes can help health care organizations advance the user-centered innovation strategies promoted by federal health technology initiatives [63]. Collaboration among academia, health care providers, and technology developers can further drive innovation tailored to the evolving needs of older adults.

Promoting Health Involvement Through Guided Support

Health care providers can encourage older adults' active participation in managing their health through targeted education campaigns that highlight the practical benefits of ePHRs. Public health strategies that emphasize patient-provider communication, administrative ease, and improved health care outcomes can be strengthened by incorporating user testimonials and success stories [67]. Additionally, guided tutorials embedded within ePHRs can further support patient engagement, aligning with strategies recommended by the Agency for Healthcare Research and Quality for patient empowerment [68].

Implementing these recommendations, grounded in existing US health care policies and strategies, can significantly enhance ePHR adoption among older adults, help reduce health disparities, and promote a more efficient and patient-centered health care system.

Limitations

This study has several limitations that should be considered. First, the use of secondary data from the HINTS limited the analysis to variables available in the dataset. Important factors, such as detailed measures of digital literacy or prior technology experience, could not be examined. Further, this study included only individuals who reported using ePHRs at least once in the past 12 months, as key variables of interest were not captured for those who had not used ePHRs. Additionally, some variables in this study were measured using single-item scales, which may lack the robustness of multi-item measures. However, single-item measures are considered acceptable when the constructs are straightforward and unambiguous [52]. We acknowledge that single-item measures inherently do not allow for traditional assessments of internal consistency reliability, which presents a limitation in this study. This limitation necessitates cautious interpretation of the findings. Future research should aim to incorporate multi-item scales where feasible and conduct reliability analyses to ensure the stability and consistency of these measures.

Second, the reliance on self-reported data introduces the possibility of CMV, which could inflate relationships between variables [59]. To address this concern, the study applied the marker variable technique [53], which confirmed that CMV was not a significant issue. Third, the cross-sectional design of the study limits the ability to establish causal relationships among the variables. Longitudinal research is needed to explore how factors such as self-efficacy and performance expectancy influence the use of ePHRs over time. Fourth, although the use of survey weights enhances the representativeness of the sample for the United States, the relatively small sample size remains a limitation that future research with a more targeted approach could address. Additionally, we did not control for factors such as income, digital literacy, and prior technology experience, as these variables were not accessible in the dataset. The absence of these controls may limit the completeness of the study. Future research should incorporate these variables to provide a more comprehensive understanding of the frequency of HIT use among older adults. Finally, the findings are specific to the US context and may not fully generalize to other populations or health care systems. Despite these limitations, the study offers valuable insights and lays important groundwork for future research.

Conclusions

This study emphasizes the important role of ePHRs in empowering older adults to manage their health and maintain independence. By utilizing survey weights, the findings can be generalized to the broader US population, making them particularly relevant as the aging demographic continues to grow. Unlike previous research, this study reveals a positive relationship between age and the level of ePHR use, challenging the common assumption that older adults are reluctant to adopt health technologies.

Key factors driving ePHR usage are performance expectancy, effort expectancy, self-efficacy, and issue involvement, all of which offer actionable pathways for increasing the frequency of use among older adults. Raising awareness of the practical benefits and ease of use of ePHRs can encourage more frequent engagement. Additionally, addressing usability concerns and emphasizing the relevance of ePHRs to individual health needs can further promote their adoption. Frequent use of ePHRs empowers older adults to manage chronic conditions, access vital health information, and make informed decisions, ultimately enhancing their quality of life.

As health care systems strive to meet the challenges posed by an aging population, integrating ePHRs into routine care and ensuring equitable access can provide both social and economic benefits. This study lays the groundwork for targeted interventions aimed at bridging the digital divide and fostering a more inclusive, health-empowered society for older adults.

Abstract

Background: The integration of technology in rehabilitation is transforming health care delivery for older adults, especially through telerehabilitation, which addresses barriers to in-person care.

Objective: This rapid review explores the ethical and equity concerns associated with telerehabilitation for older adults, focusing on challenges such as internet access, technology adoption, and digital literacy.

Methods: Conducted according to Cochrane Rapid Review guidelines, this review used the Metaverse Equitable Rehabilitation Therapy framework, focusing on equity and ethics. Studies included telerehabilitation services for adults aged 55 years and older, published between 2010 and 2023. Screening was conducted independently by 2 researchers using Rayyan (Qatar Computing Research Institute, Hamad Bin Khalifa University), with full-text review by additional team members. Searches were performed in Medline and CINAHL

Results: From 323 papers retrieved, 49 studies met the inclusion criteria. The included studies were published between 2013 and 2023. Disparities in socioeconomic status, geographic location, and racial and ethnic backgrounds were found to impact telerehabilitation use. Additionally, ethical concerns around privacy, security, and autonomy were often inadequately addressed.

Conclusions: This review emphasizes the need for culturally appropriate, accessible, and inclusive telerehabilitation services that integrate ethical and equity considerations into their design and delivery.

Introduction

The use of technology in rehabilitation is increasing worldwide, including its application in delivering services to the older adults population [1]. This is transforming how health care services are delivered to the aging population [2]. Telerehabilitation, which involves the evaluation and treatment of patients through technology, has emerged as an attractive option for older adults who may have multiple comorbidities [1,3]. Before the COVID-19 pandemic, numerous adults faced challenges accessing rehabilitation treatments due to diverse clinical limitations and geographic circumstances. Telerehabilitation has assumed greater importance in addressing the needs of older adults, as the COVID-19 pandemic exacerbated difficulties by further restricting face-to-face interactions with implementation of societal measures aimed at lowering disease prevalence [4].

When older adults experience complex medical needs, whether due to multiple chronic conditions or acute illnesses, it can lead to increased dependence on others and diminish the quality of life for both the individuals and their caregivers [5]. Health care

technologies can help overcome these challenges and enhance the well-being of the aging population by improving access to rehabilitation [5]. In this context, telerehabilitation provides an alternative platform for delivering health education and care to clients in clinical, community, or home care settings [6]. However, challenges in delivering telerehabilitation to older adults have been reported in the literature and include issues with internet access, adoption of technology, self-efficacy, experience with technology, frequency of usage, and reliance on guidance and digital literacy [7,8]. Other barriers reported in a systematic review about the use of telehealth use among older adults were trust of internet information, reading small fonts, information overload, clicking small icons, interacting with scroll bars, lack of understanding of app capabilities, fear of others overhearing, security, need for support to use, cost, privacy concerns, among others [8].

Despite the numerous benefits of telerehabilitation for older adults, this is recognized as an extremely heterogeneous population; therefore, there is a pressing need to investigate and understand the ethical and equity concerns associated with these services. No reviews to date have thoroughly explored these aspects, which is critical given the reported challenges. Knowing about these problems is important to help address the effectiveness and accessibility of telerehabilitation. Ethical concerns may arise regarding the confidentiality of patient information, while equity issues could stem from disparities in access to technology and the internet among different socioeconomic groups, for example. Addressing these concerns is essential to ensure that telerehabilitation services are delivered fairly and effectively, promoting better health outcomes and quality of life for all older adults. This review aims to examine these concerns and explore telerehabilitation for older adults over the past 10 years.

Methods

Study Design

Rapid reviews are a form of synthesis that accelerates the traditional systematic review process, facilitating the dissemination of literature in a resource-efficient manner, particularly relevant in the context of rapidly advancing technology research [9]. This rapid review aimed to explore and summarize the current literature on the equity and ethical concerns associated with delivering telerehabilitation services, following the Cochrane Rapid Review guidelines [9]. To guide the data extraction and analysis of this review, the Metaverse Equitable Rehabilitation Therapy (MERTH) framework [10] was applied, adapted to telerehabilitation, with a focus on equity (accessibility, inclusivity, diversity, fairness, and cultural relevance), health services integration (responsiveness, continuity of care, and autonomy to participate in health-related decisions), interoperability, and humanization (communication, person-centered care, and empowerment) [10]. For this article, we are focusing on equity (accessibility, inclusivity, diversity, fairness, cultural relevance) and empowerment.

We included studies that focused on telerehabilitation services for both older adults and middle-aged individuals aged 55 years and above. The inclusion criteria focused on reviews (systematic reviews, scoping reviews, meta-analyses, and narrative reviews with descriptions of included studies) involving older adults aged 55 years and older, which includes the older working-age population (55 to 64 y) [11]. This age range was selected to include individuals who may benefit from telerehabilitation services, considering their potential health care needs and technological engagement during this phase of life. These studies were selected if published between 2010 and 2023. Editorials, conference abstracts, and papers without full text available were excluded. Two researchers (MV and NG) independently completed the title and abstract screening using Rayyan [12], an online app that accelerates initial screening of abstracts and titles for managing reviews. One reviewer (MV) performed the full-text screening, and any doubts regarding inclusion were discussed with MV, DK, and JS. DK, JS, NG, and MV developed a data extraction tool and refined it throughout the extraction process. For added rigor, a sample of the data, such as 10% (13/125) of the reviews at the abstract phase, was independently reviewed by another team member (DK or JS).

To conduct the search, we consulted a specialized health sciences library. We tailored a search strategy for 2 databases: Medline and CINAHL.

Detailed search strategies can be found in Multimedia Appendix 1.

Ethical Considerations

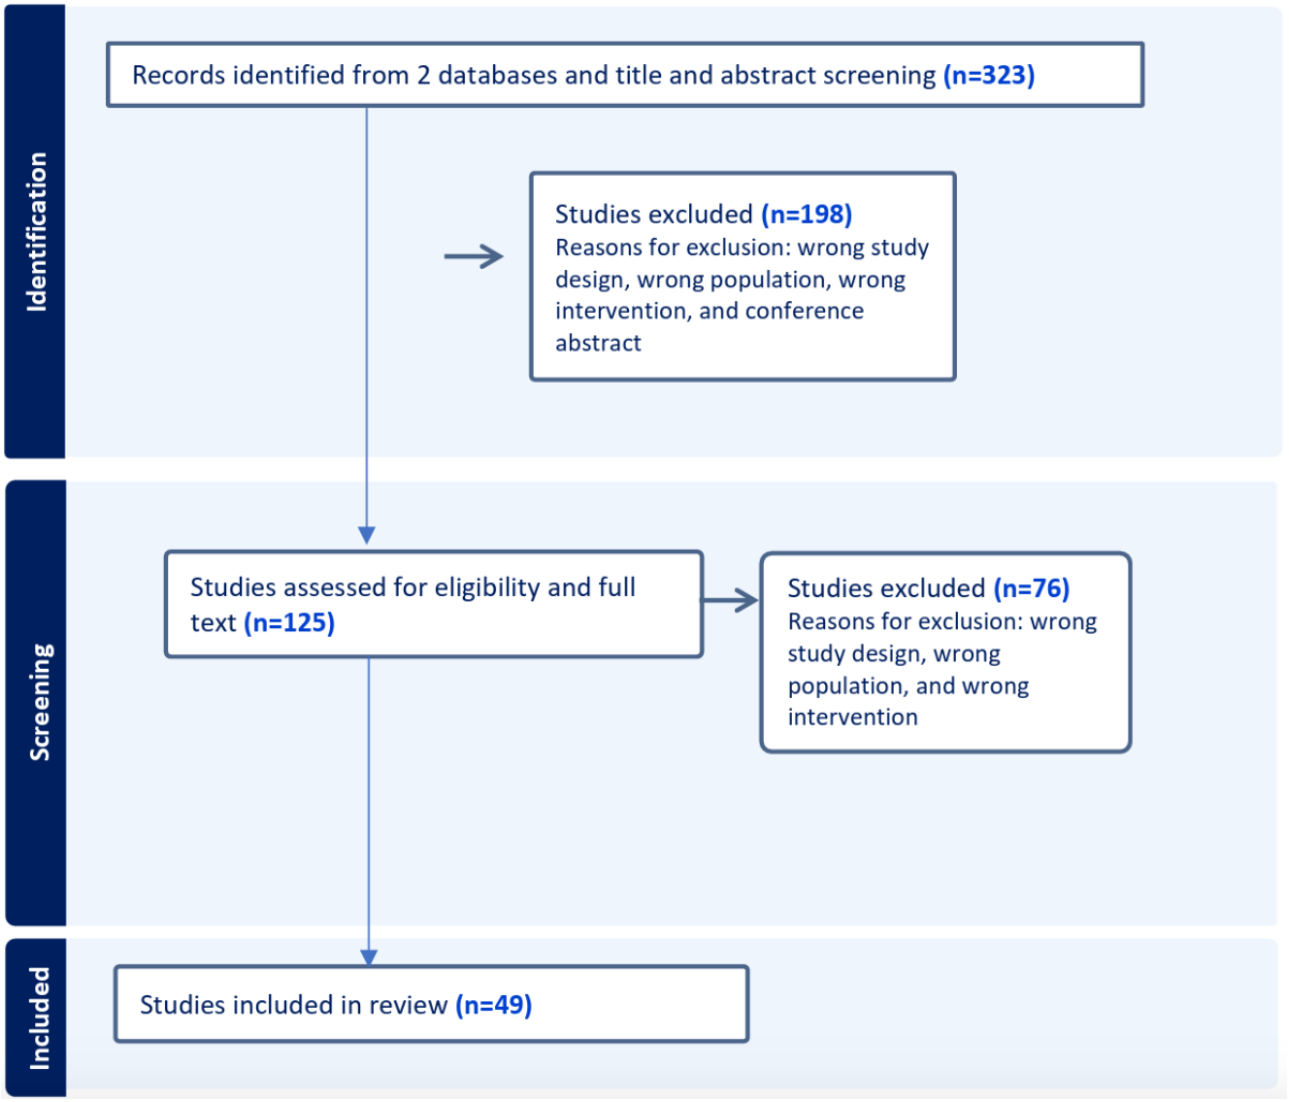
This study is a review of existing literature and does not involve any primary data collection or direct interaction with human participants. Therefore, ethical approval and consent for publication are not required. All sources cited have been appropriately referenced per academic standards.

Results

Overview

Figure 1 provides an overview of the review process. Initially, 323 papers were retrieved through the search. After title and abstract screening, followed by full-text review, 49 studies met the criteria for extraction and final evaluation.

Figure 1. Flow diagram of study selection.



Publications Characteristics

The included review studies were published between 2013 and 2023. Approximately 39% (n=19) of the studies were published in 2021. The included studies predominantly consisted of systematic reviews (22 studies), systematic reviews and meta-analyses (11 studies) followed by scoping reviews (8 studies; Table S1 in Multimedia Appendix 2 [6,13-60]).

Morbidities

Cardiorespiratory, neurological, and musculoskeletal conditions are the primary morbidities present in the studies identified in this review. Other key categories include cognitive impairment and mental health, cancer, and diabetes. Less frequently studied morbidities include vision and hearing problems, balance disorders, risk for falls, and pelvic floor disorders. The distribution of included studies (n=49) across morbidity categories revealed that the most commonly addressed condition was cardiorespiratory, featured in 33/49 (67%) of the studies. Neurological and musculoskeletal conditions followed this, each reported in 17/49 (35%) of the studies. Studies categorized under "other" comprised 15/49 (31%). Cognitive impairment and mental health, and cancer were each represented in 9/49 (19%) of the studies. Diabetes was addressed in 6/49 (13%), while vision and hearing problems, balance disorders and risk for falls, and pelvic floor disorders were the least represented, each occurring in 2/49 (5%) of the included studies. These findings indicate a predominant research focus on cardiorespiratory and neuromusculoskeletal morbidities.

It is important to note that individual morbidities can be counted in more than 1 study within these reviews and that each study could include participants with several morbidities. This repetition highlights the prevalence and importance of specific categories of health issues within the reviewed literature.

Type of Technologies Used in Telerehabilitation for Older Adults

Within the included reviews, the categorization of communication technologies in telerehabilitation included several key areas, each highlighted by different examples and applications. Communication technologies included eHealth platforms such as telehealth, telemedicine, and telerehabilitation, which used tools such as videoconferencing (Skype [Microsoft Corp] and Zoom [Zoom Communications, Inc]), telephones, text messaging, emails, and web-based platforms. Telemonitoring and remote monitoring were used through health

monitoring systems, wearable sensors, and mobile health apps for tracking health metrics. Virtual and augmented reality were applied in digital rehabilitation systems and exergames such as Wii Fit (Nintendo Entertainment Analysis & Development) and Kinect (Microsoft). Wearable technology included sensors, smartwatches, and fitness trackers. Education and support tools provided digital health education via e-learning apps and digital pain coaches. Digital and assistive technologies enhanced patient engagement and supported independent living through interactive internet platforms and emergency assistance systems. Finally, home-based rehabilitation and exercise facilitated remote rehabilitation exercises with personalized programs and activity trackers (Table 1)

Based on the studies included in this rapid review, the most frequent categories of technologies used are communication technologies, including telemonitoring and remote monitoring, which appear in 73% of the included studies. In contrast, the least used categories are virtual and augmented reality and interactive and assistive technologies, each appearing in 12% of the studies. Specifically, virtual and augmented reality were found in 6 studies, which corresponds to approximately 12% of the total studies. The total percentage exceeds 100% due to the overlap of studies across multiple categories (Table 1).

Table . Study characteristics: technologies used and examples.

Categorization	Examples	References
Communication technologies	• eHealth platforms: telehealth interventions, telemedicine, and telerehabilitation platforms • Telehealth devices: remote supervision tools, home-health monitoring systems, and teleconsultation platforms Videoconferencing: Skype (Microsoft Corp), Zoom (Zoom Communications, Inc), FaceTime (Apple Inc), Adobe Connect, and Microsoft Teams • Telephone and mobile phones: standard calls, smartphones, and telephone support • Text messaging and emails: SMS and email • Web-based platforms: online multimedia, discussion boards, blogs, and web-based health management portals	[6,13-42,60]
Telemonitoring and remote monitoring	• Health monitoring systems: heart health monitoring system, wearable sensors, pulse oximeters, and blood pressure monitors • Telemonitoring devices: ECG[a], heart monitors, Bluetooth-powered sensors, and wireless transmitters • Mobile health apps: apps for tracking health metrics and remote wound care applications	[6,13,18,21-23,26,28,30,35,37,39,43-50]
Virtual and augmented reality	• Virtual rehabilitation systems: virtual reality–based rehabilitation and interactive virtual reality exercises • Exergames: Wii Fit (Nintendo Entertainment Analysis & Development), Kinect (Microsoft), VRc[b] video game dancing, and interactive gaming systems	[6,19,23,51,52,61]
Wearable technology	• Sensors and monitors: inertial sensors, accelerometers, gyroscopes, and pedometers • Wearable devices: smartwatches, fitness trackers, and wearable pressure	[6,19,21,41,43-46,53,59]
Education and support tools	• Provides health education and support through digital tools. Examples: e-learning apps, digital pain coaches.	[6,14,15,17,21,23,26,30,36,38,45,46,50,54-56]
Interactive and assistive technologies	• Enhances patient engagement and supports independent living. Examples: interactive internet platforms, emergency assistance	[17,22,39,50,53]
Home-based rehabilitation and exercise	• Facilitates rehabilitation exercises at home with remote guidance. Examples: personalized exercise programs, activity trackers.	[6,15,21,22,24,35,43-45,47,48,50,52,53,55]

[a]ECG: electrocardiogram.

[b]VR: virtual reality.

Equity

Sex or Gender

Twenty-nine reviews included at least 1 study that reported findings on gender (Table S1 in Multimedia Appendix 2). The reviews that reported sex or gender in their results did not provide a full analysis based on these variables. However, 2 studies included some comments related to their gender or sex results.

One review reported that the findings regarding gender and the use of eHealth are mixed. “Out of 22 articles, only five suggest that gender plays a role in influencing eHealth usage, while eight studies found no connection between gender and eHealth use.” The studies did not define gender, underscoring the importance of clearly specifying sex, gender, and sexual orientation within the included population. Additionally, 3 studies highlight that women tend to be more engaged with and satisfied by eHealth apps, using them more frequently than men

[13]. In 1 review, the authors mentioned a gender bias, with more male participants than female participants [6]. In another study, the authors noted that most of the studies included more women than men. Four studies included only women. One study explained this decision as "to avoid the influence of gender differences on the risk of falling." Two studies excluded the few male participants, and another study did not provide a reason for the exclusive participation of women. Additionally, 1 study did not describe the age range or gender distribution of the participants [43].

Ethnicity

Racial differences in telehealth care use were observed, with cultural minority groups. For instance, 1 study found no significant effect of telehealth interventions on older Hispanic patients with chronic heart failure [14]. Overall, most studies that reported ethnicity included predominantly White participants. The term "Caucasian" is used as a more formal and historically established term to describe people of European descent. However, it can be viewed as outdated or less inclusive compared to simply using "White" or more specific ethnic identifiers (Table S1 in Multimedia Appendix 2).

Geographic Location

Older adults with chronic diseases residing in rural areas are less likely to use eHealth services compared to their urban counterparts, primarily due to limited access and lower socioeconomic status. Rural inhabitants face greater barriers to the effective implementation of eHealth, often related to insufficient infrastructure and resources. Contrarily, some regions, such as certain cities in South Korea with limited medical facilities, have shown a higher adoption of eHealth compared to more urbanized areas, highlighting the potential benefits of these technologies in underserved locations [13] (Table S1 in Multimedia Appendix 2).

Socioeconomic Status

One study highlighted that despite lower-income groups often facing barriers in accessing eHealth technologies due to economic constraints, their satisfaction levels with using these technologies were found to be comparable to those of higher-income groups once they had access (Reiners et al, 2019) [13]. This suggests that while income initially affects access to eHealth services, it may not impact the perceived benefits and satisfaction derived from using them once accessibility barriers are overcome.

Barriers

Digital barriers: the following summaries highlight the main challenges and associated studies for each category concerning the adoption of telerehabilitation among older adults:

Economic barriers: affordability of technology is an obstacle for older adults and those with lower educational backgrounds (Bertolazzi et al, 2024 [57] and Bhattarai and Phillips, 2017 [15]).

Usability challenges: difficulty in using mHealth technologies hinders adoption, exacerbated by lack of exposure (Johnson et al, 2021) [44].

Digital literacy disparities: lower digital literacy among racial or ethnic minorities, low-income groups, and people with sensory and manual dexterity deficits impact technology acceptance (Yi et al, 2021 [58]; Johnson et al, 2021 [44]; Jonker et al, 2020 [45]; Bertolazzi et al, 2024 [57]; Bostrom et al, 2020 [46]; Beckie, 2019 [16]; Gaspar and Lapão, 2021 [43]);

Support from family members: family encouragement aids acceptance and use of eHealth technologies (Jonker et al, 2020) [45].

Technology design and training: user-friendly designs and proper training enhance technology adoption (Johnson et al, 2021 [44] and Bhattarai and Phillips, 2017 [15]).

Inclusion and accessibility: addressing barriers such as income and education levels is crucial for equitable access (Bertolazzi et al, 2024) [57].

Health care provider involvement: clinician support and effective information flow facilitate technology adoption (Bhattarai and Phillips, 2017) [15].

Costs

The results related to digital health technology costs are structured into several key categories: costs, benefits, equity considerations, and policy implications. First, the section on cost details the financial implications of adopting digital health technologies, highlighting initial investments, ongoing maintenance costs, and cost analyses. Second, the benefits category outlines the positive impacts of these technologies on telerehabilitation, such as improved patient outcomes, enhanced efficiency, and reduced health care disparities. Third, equity considerations address how digital health technologies can potentially bridge gaps in health care access and outcomes among the older adult population. Lastly, the section on policy implications describes regulatory frameworks, privacy concerns, and recommendations for effective implementation strategies (Table S1 in Multimedia Appendix 2).

Overview of Costs in Digital Health Technology

Background of Costs in Digital Health Technology

Digital health technologies include a range of costs associated with implementation and operation. The following provides a summary of findings concerning cost considerations, supplemented with insights from the studies reviewed. For detailed examples and other comments, examples can be found in Table S1 in Multimedia Appendix 2.

General Cost Implications

Telehealth technologies are often highlighted as cost-effective strategies, particularly in reducing hospital and nursing home expenses.

Cost-Effective Strategies

For instance, telehealth has been proposed as cost-effective for delivering health education and promoting self-monitoring behaviors among older adults with chronic conditions.

Cost Types

Costs in digital health include implementation activities and operational expenses related to eHealth applications.

Specific Cost and Benefit Types

Patient Outcomes

Studies predominantly capture patient outcomes through quality-of-life considerations and physical health status indicators (summary of results of the included studies).

Resource Use

Emphasis is placed on reducing home care visits and hospital usage through remote monitoring, aimed at preventing unnecessary hospital admissions (results of included studies).

Equity and Access Considerations

Gender and Socioeconomic Variables

These variables influence the usability and adoption of digital health technologies, highlighting disparities in access and usage (comment on discussion of included studies).

Racial and Ethnic Differences

Studies note disparities in telehealth use among different racial and ethnic groups, suggesting cultural acceptance and access barriers.

Geographic and Socioeconomic Factors

Access to and effectiveness of telerehabilitation are influenced by factors such as geographic location and socioeconomic status, with rural and lower-income populations facing greater challenges.

Recommendations and Future Directions Related to Costs

Addressing Barriers

Recommendations include designing culture-friendly and accessible telehealth services to enhance engagement among diverse populations.

Policy Implications

Policy makers are urged to minimize cost barriers, provide subsidies for technology access, and promote equitable health technology adoption.

Ethics

Overview

Twenty-five studies reported some ethical aspects of the included studies. The following ethical aspects of the included studies can be categorized into safety, adverse events, privacy, empowerment, respect and knowledge of cultural diversity, and inclusion of ethics in research design.

Safety and Adverse Events

Safety concerns focus on ensuring that interventions do not cause harm to participants. Studies highlight that most interventions were safe, with no substantial adverse events reported (Huang et al, 2020 [17]; Malaguti et al, 2021 [18]; Johnson et al, 2021 [44]; Kraaijkamp et al, 2021 [19]; Bostrom et al, 2020 [46]; Gaspar and Lapão, 2021 [43]; Reeder et al, 2016 [20]; Solis-Navarro et al, 2022 [31]). The adverse events category pertains to the reporting and management of negative outcomes associated with interventions. Some studies mentioned the importance of feasibility testing to identify potential adverse events (Dennette et al, 2021 [21]; Kraaijkamp et al, 2021 [19]; Devi et al, 2015 [22]; Dequanter et al, 2021 [23]; Ambrens et al, 2022 [24]; Del Pino et al, 2022 [47]; and Ding et al, 2023 [25]).

Privacy

Concerns about maintaining the confidentiality and privacy of participant data were noted, emphasizing the need for secure data handling and adherence to privacy regulations (Yi et al, 2021 [58] and Jonker et al, 2020 [45]).

Respect and Knowledge of Cultural Diversity

This category highlights the importance of culturally appropriate interventions, especially for Indigenous older adults, and includes the use of culturally relevant content and rewards (Choukou et al, 2021 [26]).

Empowerment

In 1 study, the authors highlighted the empowerment divide, noting that despite having access to the necessary hardware and skills to use eHealth apps, some individuals did not use these opportunities because they did not feel personally empowered or believe they would benefit. While the reviewed papers primarily addressed economic and usability divides, the authors emphasized that future research should specifically focus on overcoming the empowerment divide (Reiners et al, 2019 [13]).

Inclusion of Ethics in the Design of the Interventions

Several studies highlighted in their discussion the importance of incorporating ethical considerations in the design and implementation of interventions. This includes respecting client preferences, obtaining informed consent, and addressing ethical and privacy concerns (Saito and Izawa, 2021 [27]; Sulz et al, 2021 [28], Su et al, 2020 [29]; Theodoros et al, 2019 [30]; and Tao et al, 2018 [42]).

Our review showed that 26 studies did not address the ethical aspects of their interventions. However, among those that did, several key ethical considerations emerged. Safety was a primary focus, with studies generally reporting no adverse events associated with the interventions (Huang et al, 2020 [17]; Malaguti et al, 2021 [18]; Johnson et al, 2021 [44]; Kraaijkamp et al, 2021 [19]; Bostrom et al, 2020 [46]; Gaspar and Lapão, 2021 [43]; Reeder et al, 2016 [20]; Solis-Navarro et al, 2022 [31]). Adverse event management was emphasized through feasibility testing (Dennette et al, 2021 [21]; Kraaijkamp et al, 2021 [19]; Devi et al, 2015 [22]; Dequanter et al, 2021 [23]; Ambrens et al, 2022 [24]; Del Pino et al, 2022 [47]; Ding et al, 2023 [25]).

Privacy concerns were frequently mentioned, highlighting the need for secure data handling and compliance with privacy regulations (Yi et al, 2021 [58]; Jonker et al, 2020 [45]). Empowerment was also critical, with studies stressing the importance of making participants feel capable and confident in using eHealth technologies (Reiners et al, 2019 [13]). Respect

and knowledge of cultural diversity were crucial, particularly for indigenous older adults, calling for culturally appropriate content and rewards (Choukou et al, 2021) [26]. Finally, the inclusion of ethics in research design was recommended, advocating for respect for client preferences, informed consent, and addressing ethical and privacy issues throughout the intervention process (Saito and Izawa, 2021 [27]; Sulz et al, 2021 [28]; Su Jing, 2020 [29]; Theodoros et al, 2019 [30]; and Tao et al, 2018 [42]). These findings emphasize the necessity of integrating comprehensive ethical considerations into digital health interventions to ensure safety, privacy, and respect for all participants.

Discussion

Principal Findings

The distribution of morbidities highlights areas where research is concentrated and indicates potential gaps in the literature that warrant further investigation, such as vision and hearing problems, balance disorders, risk of falls, and pelvic floor disorders. This distribution might also reflect conditions that health professionals are more comfortable managing. Therefore, there is a need to develop strategies to offer remote rehabilitation services for these conditions as well.

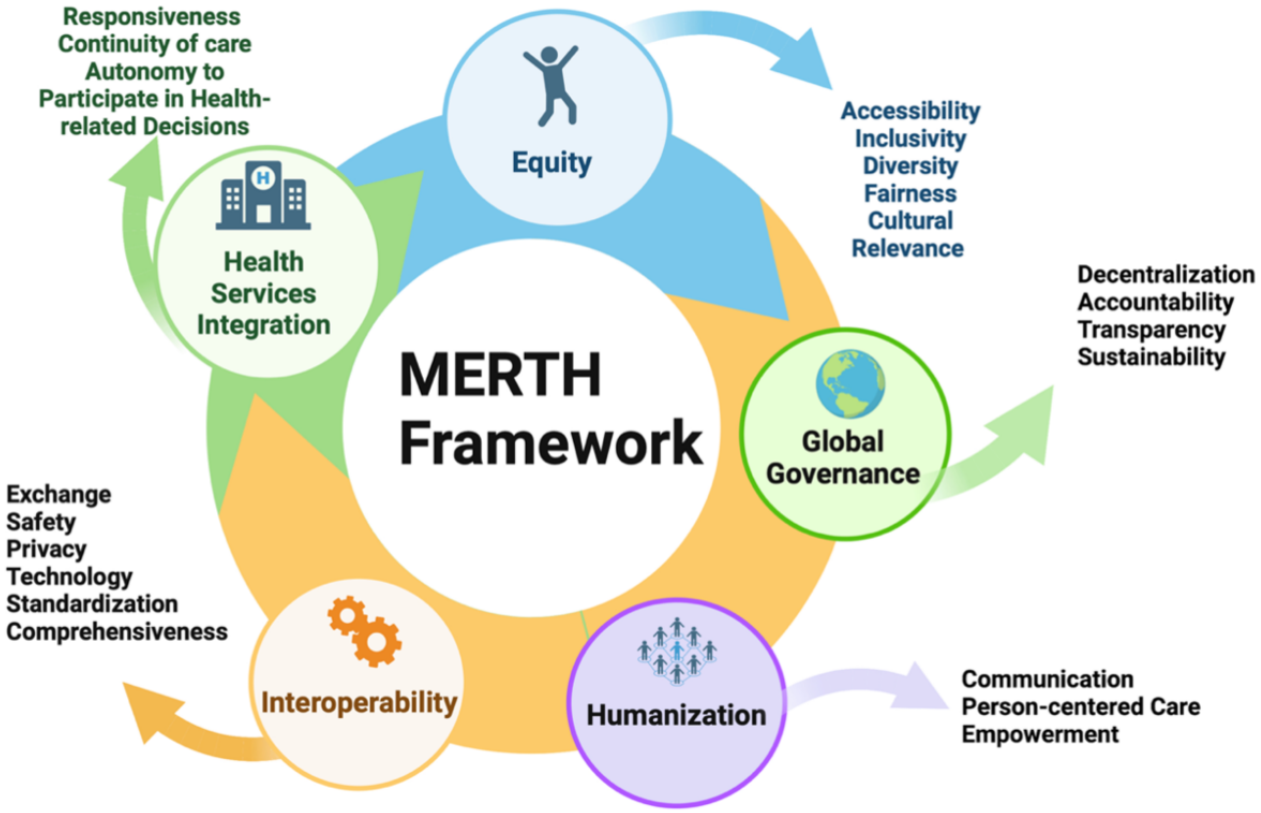
Older adults have a higher prevalence of chronic obstructive pulmonary disease, a trend that is expected to rise substantially in the coming decades due to aging populations and prolonged exposure to risk factors [62]. It has been estimated that between 55% and 98% of older adults aged 60 years and older have at least 2 chronic diseases, known as multimorbidity. Among these, cardiovascular diseases are the most common [63]. This aligns with our findings that cardiorespiratory issues were the most frequently studied morbidity type.

When considering the Health Services Integration of the MERTH framework (Figure 2), the need for continuity of care and responsiveness becomes even more evident [10]. To effectively address the complex health needs of older adults, particularly those with multiple chronic conditions, health systems must be able to provide integrated and coordinated care across various settings and providers. This not only involves traditional clinical care but also includes social support systems and digital resources, which are increasingly important for managing aging-related health issues [10].

Incorporating telerehabilitation could be a key part of achieving this integration. These digital platforms can help bridge gaps in health care access and ensure that patients receive consistent care, no matter their location or mobility [10]. They also offer an innovative way to enhance autonomy in decision-making, allowing patients to engage in their rehabilitation process more actively and with greater flexibility. This is especially important as older adults may have difficulties attending in-person sessions due to transportation issues or other physical limitations.

In the rapid review, communication technologies, telemonitoring, and remote monitoring were the most frequently included categories, totaling 38 reviews. In contrast, virtual and augmented reality, as well as interactive and assistive technologies, were less frequently cited, with only 6 reviews each. This distribution indicates a stronger focus on technologies that enable direct communication and continuous health monitoring, while immersive and interactive technologies, though valuable, are less commonly studied.

Figure 2. MERTH framework [10]. MERTH: Metaverse Equitable Rehabilitation Therapy.



This review highlights several key factors influencing the use and effectiveness of telerehabilitation services across different demographics. Racial disparities are evident, with cultural minority groups often showing lower acceptance of telehealth. For instance, 1 study found no significant impact of telehealth interventions on older Hispanic patients with chronic heart failure, indicating that cultural differences may influence outcomes. There is a substantial research gap in addressing racial differences in telerehabilitation, and the current literature primarily identifies barriers without proposing solutions to promote racial equity in telerehabilitation use. To ensure successful interventions, health care providers must design and deliver culturally friendly telerehabilitation services tailored to their target patients. Future research should focus on exploring these racial differences further and developing strategies to enhance the acceptance and effectiveness of telerehabilitation among diverse racial and ethnic groups.

Geographic location also plays a crucial role, with older adults in rural areas less likely to use telerehabilitation services due to limited access and lower socioeconomic status. These rural barriers often stem from insufficient infrastructure and resources, although some regions, such as certain South Korean cities with limited medical facilities, have shown higher eHealth adoption, demonstrating the potential of these technologies in underserved areas [13]. The overall trend emphasizes a persistent urban-rural divide in telerehabilitation usage, necessitating targeted efforts to improve access and infrastructure in rural areas to ensure equitable health care delivery.

Socioeconomic status further influences telerehabilitation use; lower-income groups face initial access barriers but report satisfaction levels comparable to higher-income groups once they gain access, indicating that economic constraints primarily affect initial accessibility rather than ongoing satisfaction and perceived benefits. The study on gender disparities in telehealth use among older adults in the United States during the COVID-19 pandemic provides relevant results for comparison with our review. It showed a significant increase in telehealth use among females during the pandemic, influenced by factors such as multimorbidity, tablet ownership, and learning new technologies. Males with similar factors also had higher odds of telehealth use [64]. Although some reviews in our study mentioned gender differences, they did not provide much detailed information. These findings emphasize the necessity for targeted interventions to enhance older adults' access to telerehabilitation services and mitigate digital disparities, aligning with our review's emphasis on the need for equitable access across diverse populations.

The reviews included in this analysis did not provide a detailed discussion on gender, sexual orientation, or the distinction between sex and gender. While the term "gender" may have been used in some instances, it was not consistently defined or explored in the context of the studies reviewed. In fact, many of the reviews primarily focused on sex-based differences, and in some cases, the term "gender" may have been used interchangeably with sex without clarifying the distinction. Additionally, there was no substantial examination of sexual orientation, and these factors were not adequately addressed or analyzed across the included studies. To provide a more comprehensive understanding of how these variables influence telerehabilitation outcomes, future research should ensure a clear and explicit discussion of gender, sex, and sexual

orientation, and their potential impact on the accessibility and effectiveness of telerehabilitation services.

Digital literacy plays a significant role in the adoption of telerehabilitation among older adults, with several key challenges highlighted in this review. Economic barriers, such as the affordability of technology, pose significant obstacles, particularly for older adults and those with lower educational backgrounds. Usability challenges, often exacerbated by a lack of exposure to health technologies, further hinder adoption. Studies show that enhancing internet use among older adults can significantly improve their access to health information and their ability to manage their health [65,66].

Disparities in digital literacy are particularly pronounced among racial or ethnic minorities, low-income groups, and individuals with sensory and manual dexterity deficits, affecting technology acceptance and use. Family support has been shown to aid in the acceptance and use of health technologies, while user-friendly design and proper training can significantly enhance adoption rates. A randomized controlled trial on technophilia (enthusiasm toward new technologies) among people with dementia or mild cognitive impairment and their caregivers demonstrated technophilia was lower among persons with disabilities influenced by factors such as younger age, male gender, higher education, better health, and depression. For caregivers, lower burden and better quality of life also contributed [67]. The sensory and manual dexterity deficits can significantly impact how individuals accept and use technology. These challenges highlight the importance of designing inclusive technology solutions that accommodate a diverse range of physical abilities, ensuring equitable access and usability for all users. Addressing all these barriers is crucial for ensuring equitable access to these technologies.

In terms of accountability, as per the MERTH framework, telerehabilitation services must maintain high standards of care despite these barriers. One area where accountability becomes particularly important is in ensuring that health care providers are properly trained and equipped to offer culturally competent and accessible digital care [10]. As there is a disparity in the acceptance and effectiveness of telerehabilitation across different demographics—such as rural versus urban populations, and racial or ethnic minorities—health care providers must be held accountable for creating inclusive services. This includes adapting technologies to be more accessible, as well as implementing feedback mechanisms to assess the effectiveness of interventions.

Cost considerations include initial investments and ongoing maintenance, but digital health technologies are generally seen as cost-effective, particularly in reducing hospital and nursing home expenses [14,68,69]. To maximize benefits and ensure equity, it is important to design culturally friendly and accessible telerehabilitation services, minimize cost barriers, and promote equitable technology adoption across diverse populations [14]. These findings support our review results on the need for targeted interventions to improve access to telerehabilitation services and reduce digital disparities among older adults.

Regarding ethical aspects, 26 studies did not address the ethical aspects of their interventions. This gap in addressing ethical considerations highlights a substantial shortcoming in the research, underscoring the need for more rigorous ethical evaluation in future studies. However, for the studies that did address ethics, several key considerations came to light. Safety was reported as a comment or result with no significant adverse events associated with the interventions. Adverse event management was emphasized through feasibility testing. A recent scoping review of risks, adverse effects, and mitigation strategies in delivering mental health services via telehealth, emphasizes the growing recognition of the importance of adverse event reporting in telehealth. However, it also highlights the lack of standardized protocols for this purpose [61]. Challenges persist in the telerehabilitation regarding the systematic collection and evaluation of adverse events. The study urges improved reporting of near-misses and actual incidents to enhance risk management. It also advocates for comprehensive clinical training to prevent adverse events and proposes the establishment of robust reporting mechanisms to promote ongoing enhancements in telehealth practices [61]. There is a clear and pressing need to establish standardized protocols for reporting adverse events in telerehabilitation, as highlighted by the findings. This will enable better risk management and improve the overall quality and safety of telerehabilitation services.

The review authors emphasized the importance of addressing privacy concerns and noted a lack of attention to these issues in the included studies. This highlights the need for secure data handling and adherence to privacy regulations. The studies reviewed here briefly addressed privacy and security concerns but did not thoroughly investigate these aspects. Privacy risks in telerehabilitation practice include environmental factors (such as inadequate private spaces for sensitive consultations), technology issues (including data security and limited internet access), and operational challenges [70]. The privacy concerns raised in the review align closely with elements of the MERTH framework: interoperability, particularly regarding exchange, safety, privacy, technology standardization, and comprehensiveness [10]. The challenges highlighted, such as inadequate private spaces, data security issues, and limited internet access are foundational to the safe and effective exchange of information in telerehabilitation. These issues underscore the importance of prioritizing robust data handling and adherence to privacy regulations to safeguard sensitive information of older adults [10].

Empowerment was also critical, with studies stressing the importance of making participants feel capable and confident in using health technologies. There is a noticeable gap between the digital technologies developed for older adults and what they actually need. Aging is often viewed negatively, with older adults stereotypically seen as frail and incompetent [20]. Consequently, many technologies designed for this demographic focus primarily on care rather than empowerment. These negative stereotypes commonly result in excluding older adults from the research and design processes of digital technology. Mannheim et al [71] argue that including older adults in these processes is crucial for creating technologies that genuinely enhance their well-being. Age limits are frequently justified by ageist assumptions that question the competence and reliability

of older adults. Social exclusion, driven by these stereotypes, is evident in various areas, including access to services, social relations, and research participation. Arbitrary upper age limits, which more than half of the relevant studies impose, often result in the unjustified exclusion of older adults from clinical research and randomized controlled trials. Although the use of these exclusion criteria may be declining, selective exclusion remains common [71]. These practices highlight ethical challenges in recognizing older adults' ability to participate meaningfully in research and design, underscoring the impact of stereotypes on their involvement.

This issue aligns closely with the MERTH framework's element humanization, which emphasizes the importance of person-centered care, communication, and empowerment in health care [10]. The humanization of health care, especially in the context of telerehabilitation, means creating environments where patients are treated as whole individuals, not just as a collection of symptoms or conditions. This approach fosters respect, dignity, and empowerment, encouraging patients to engage actively in their own care and decision-making. In the case of telerehabilitation and digital health technologies, this translates to providing digital spaces that not only cater to physical rehabilitation but also consider emotional, social, and psychological needs [10].

Respect and knowledge of cultural diversity were crucial, particularly for Indigenous older adults, calling for culturally appropriate content and rewards [26]. There is a lack of studies that include Indigenous older adult populations. A study conducted with Indigenous older adults in Saskatchewan showed that many express a desire to learn more about technology and recognize its value in supporting healthy aging [26]. The study highlighted that some researchers emphasized the importance of Indigenous language apps and the revitalization of cultural teachings, seeking technology's assistance in facilitating these cultural learning processes. It emphasizes the importance of considering the role of families in engaging older adults with technology, given the crucial cultural role families play within Indigenous communities [26].

The findings of this review underline the necessity of integrating comprehensive ethical considerations into telerehabilitation interventions to ensure safety, privacy, and respect for all populations.

Study Strengths and Limitations

The strengths of this rapid review include its comprehensive synthesis of a wide range of literature within a condensed timeframe, providing timely insights into telerehabilitation for older adults. This efficiency allows for a quick overview of key findings and trends, aiding health care practitioners and policy makers in making informed decisions promptly. Additionally, the review's focus on ethics and equity in telerehabilitation ensures that critical considerations around patient safety, privacy, and inclusivity are highlighted, promoting ethical standards in telerehabilitation delivery. Finally, by emphasizing the integration of diverse perspectives and the identification of gaps in current research, this rapid review contributes to advancing knowledge and guiding future investigations aimed at enhancing telerehabilitation effectiveness and accessibility for older adults.

Study limitations include language constraints, as searches were limited to English and French publications. Future research should explore strategies to access studies in all languages, particularly in equity contexts, to ensure broader inclusivity. Additionally, the review did not ascertain the specific rehabilitation professionals involved in the studies, as individual study details were not accessed, and this information was, for the most part, not presented in the reviews. Furthermore, data extraction was conducted by a single reviewer, which may have introduced potential biases. To address this, the single reviewer discussed the results with the team and engaged in iterative discussions to mitigate any potential biases. Additionally, to further ensure accuracy, 10% of the reviews, including abstracts, were independently cross-checked by another team member. These limitations highlight the need for comprehensive approaches in future reviews to enhance inclusivity and rigor in synthesizing evidence across diverse contexts and disciplines.

Conclusions

In conclusion, this review has shed light on the distribution of studies across various health conditions within telerehabilitation contexts, emphasizing a predominant focus on cardiorespiratory, neurological, and musculoskeletal conditions. These findings highlight both the areas of concentrated research and gaps, particularly in less-studied morbidities such as vision and hearing problems, balance disorders, and pelvic floor disorders.

The review also emphasizes disparities in technology adoption and research participation among different demographic groups among older and middle-aged adults, particularly highlighting racial disparities and socioeconomic influences on telerehabilitation use. Challenges persist in addressing these disparities, with rural areas facing barriers due to limited infrastructure and resources. Moreover, the review has identified ethical considerations as paramount, emphasizing the need for standardized protocols in adverse event reporting, improved privacy, and inclusive research practices that recognize and respect cultural diversity, including Indigenous older adults. Moving forward, addressing these gaps and challenges is essential to advancing equitable access to effective telerehabilitation services for older adults across diverse populations.

Abstract

Background: Digital technology in dementia is an area of great development with varying experiences across countries. However, novel digital solutions often lack a patient-oriented perspective, and several relevant barriers prevent their use in clinics.

Objective: In this study, we reviewed the existing literature on knowledge, familiarity, and competence in using digital technology and on attitude and experiences with digital tools in Alzheimer disease. The main research question is whether digital competence and attitudes of patients and caregivers may affect the adoption of digital technology.

Methods: Following the PRISMA guidelines, a literature search was conducted by two researchers in the group. Inter-rater reliability was calculated with Cohen κ statistics. The risk of bias assessment was also recorded.

Results: Of 597 initial records, only 18 papers were considered eligible. Analyses of inter-rater reliability showed good agreement levels. Significant heterogeneity in study design, sample features, and measurement tools emerged across studies. Quality assessment showed a middle-high overall quality of evidence. The main factors affecting the adoption of digital technology in patients and caregivers are severity of cognitive deficits, timing of adoption, and the availability of training and support. Additional factors are age, type of digital device, and ease of use of the digital solution.

Conclusions: Adoption of digital technology in dementia is hampered by many patient-related barriers. Improving digital competence in patient-caregiver dyads and implementing systematic, patient-oriented strategies for the development and use of digital tools are needed for a successful incorporation of digital technology in memory clinics.

Introduction

The use of digital technology for the prevention, diagnosis, management, and assistance of patients with cognitive disorders and their caregivers has witnessed a dramatic increase in recent years. Telemedicine and eHealth technology services have proven to be valuable instruments for remote support and care in neurocognitive disorders, as consistently shown during the COVID-19 pandemic (see [1,2] for examples). The severe constraints on health care resources and the reduced time available to chronic patients during the pandemic have demonstrated the urgent need for the reorganization of memory clinic services to ensure adequate diagnosis and care [3]. Accordingly, many initiatives have tested digital technology solutions and telemedicine services in dementia settings [4,5], particularly in Alzheimer disease (AD), which represents one of the highest-risk and fastest-growing burdens on the health care system [6,7]. Literature evidence showed good levels of feasibility and effectiveness, particularly in individuals living in remote or underserved geographical areas or where in-person access to care facilities is limited [8]. Overall, patients with cognitive disorders and caregivers reported good satisfaction rates for digital technology, suggesting a general propensity toward adopting it routinely [8-10].

The literature highlights various solutions, including digital diagnostic instruments, tools for active and passive monitoring, and digital technologies supporting cognitive and motor rehabilitation. These tools have shown promising results not

only in optimizing diagnostic pathways, disease management, and treatments, in avoiding dysfunctional and harmful disease trajectories, but also in helping the empowerment of patients and caregivers through active engagement in their care pathways [11,12]. However, despite the growing evidence suggesting the potential benefit of digital technology tools in cognitive patients, their integration into the daily routines of memory clinics is still limited [13].

Preliminary evidence suggested the presence of enabling factors such as familiarity, acceptability, and a positive attitude toward digital technology that could facilitate its adoption [9,13,14]. Conversely, inadequate experience with technology, poor digital literacy, and low education levels, as well as insufficient accommodation for motor and sensory impairments, may cause reduced acceptability and engagement in older adults [9,15]. However, a clear understanding of factors promoting or hampering the use of digital tools in memory clinics is still lacking.

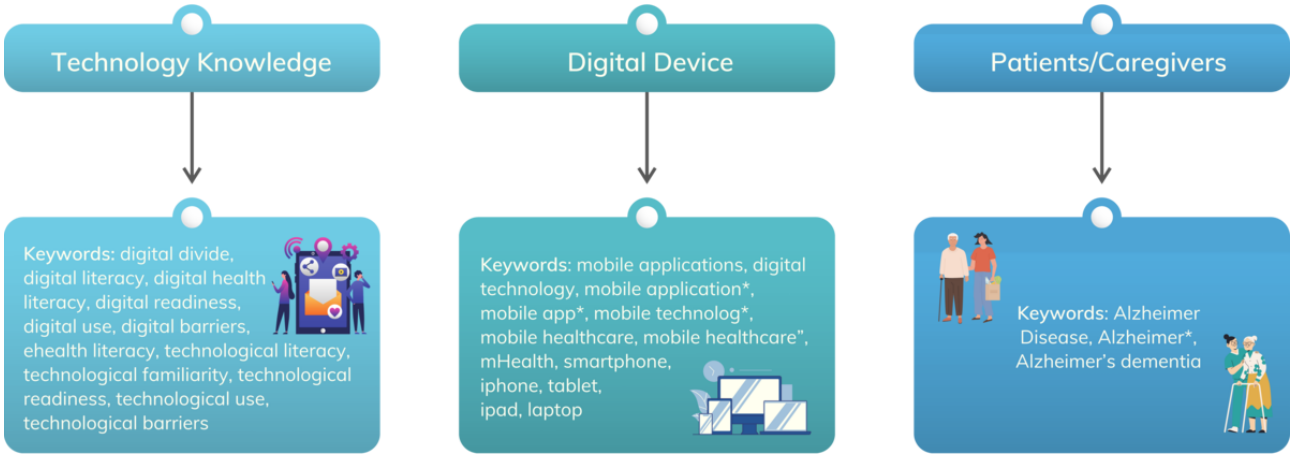
Given these considerations, we reviewed existing literature with a particular interest in studies reporting features facilitating the use of digital technology in users (eg, competence, attitudes) or evaluating the performance of digital solutions (eg, usability). The main research question is whether digital competence and the attitudes of patients and caregivers may affect the adoption of digital technology. The final goal is to explore real-world needs, facilitators, and barriers in the field and to provide patient-oriented guidance for using and implementing novel digital technology tools in memory clinics.

Methods

Search Strategy and Selection Criteria

A systematic search was conducted by two researchers of the group using PubMed, Scopus, Embase, and CINAHL (Cumulated Index in Nursing and Allied Health Literature) databases, following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [16]. According to our research hypothesis, the search strategy included a combination of MeSH (Medical Subject Headings) and relevant text terms focused on assessing familiarity and competence with digital technology and attitudes and experience regarding the use of digital solutions. See Figure 1 and Multimedia Appendix 1 for the full list of search terms. Given our theoretical framework and the growing body of literature on digital technologies in dementia, the search was focused on AD studies, aiming to improve consistency among findings.

Figure 1. Keywords for the literature search.



Inclusion criteria for paper selection were as follows: (1) paper: full original research articles (excluding conference abstracts, case reports, reviews, and book chapters); (2) population of interest: individuals with AD (ranging from mild cognitive impairment to moderate-severe dementia stages) and their caregivers; (3) measurement: papers reporting quantitative and qualitative measures (ie, questionnaires, scales, or interviews) for assessing knowledge or familiarity with digital technology and attitude or experience in using digital solutions; (4) language and time span: papers published in English from 2010 up to October 15, 2023. Articles published before 2010 were excluded due to their reliance on outdated technologies, such as personal digital assistants, which may be less relevant for a contemporary audience.

Study Selection and Data Extraction

The final set of records was uploaded onto Rayyan, a free web and mobile app designed to facilitate the initial screening of abstracts and titles through semiautomation, ensuring a high level of usability [17]. Data extraction was performed encompassing study identifiers (eg, authors, year of publication), sample features (eg, participants, diagnosis, group sizes), description of study methods (eg, type of digital solution and measurement), and findings. To ensure consistency in study selection and data extraction, the Cohen κ statistic was used to assess inter-rater reliability during the screening and eligibility phases [18]. Discrepancies were resolved through discussion, with input from an external senior expert when necessary.

Risk of Bias Assessment

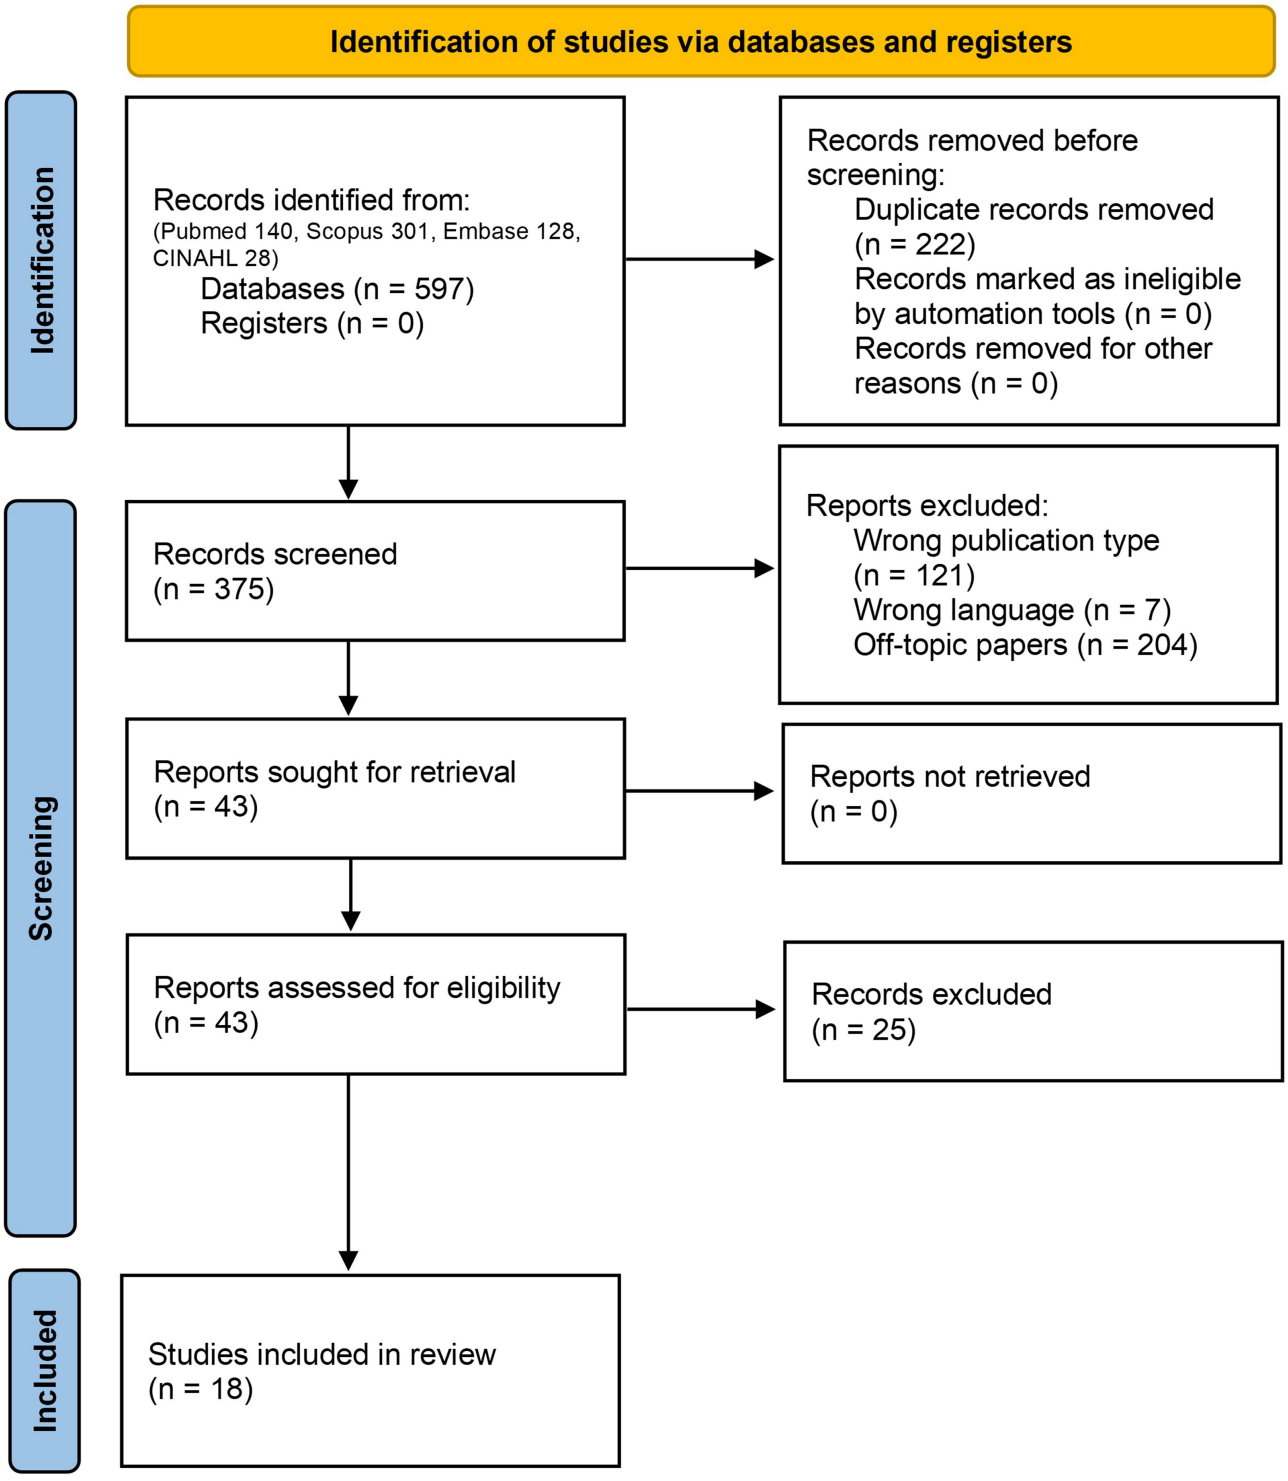
A risk of bias assessment was conducted using the Appraisal tool for Cross-Sectional Studies questionnaire [19] and the National Institutes of Health (NIH) Study Quality Assessment (SQA) Tool [20] for observational cohort and cross-sectional studies. These questionnaires evaluate the quality of human research studies, providing a global score as the rate of positive answers out of either 20 or 14 questions, and indicate overall quality and bias for each study. Considering the percentage of

positive answers, categorical ratings were devised as follows: high quality (>70%), middle (70% - 50%), and low (≤49%) quality.

Results

Out of the 597 articles initially retrieved, 554 papers were excluded during the screening phase (ie, 222 duplicates, 121 nonoriginal papers, 204 off-topic articles, and 7 articles not in English). A detailed review of the full texts led to the exclusion of 25 articles, with 18 papers meeting the eligibility criteria for this study. See Figure 2 for details of the PRISMA flow diagram. Analyses of inter-rater reliability showed good agreement levels for both the screening (κ=0.76; 94.46% agreement) and the eligibility (κ=0.75; 87.76% agreement) phases. Quality assessment of the included studies showed a middle-high quality of evidence.

Figure 2. PRISMA flowchart reporting literature search strategy. CINAHL: Cumulated Index in Nursing and Allied Health Literature.



Retained papers showed high heterogeneity in terms of study design (ie, qualitative vs quantitative), sample features (eg, patients and caregivers with various disease severity), and data type (eg, unstructured vs structured data). Given the high

methodological and population-based heterogeneity across studies, results are presented as a narrative synthesis, focusing on shared themes and distinct sources of variability rather than on statistical aggregation.

See Tables 1 and 2 for details of included papers and the quality assessment.

Table . Summary of papers exploring knowledge, familiarity, and competence with digital technology in patients with Alzheimer disease and caregivers.

Authors and country	Year	Sample	Measurements (qualitative/quantitative)	Study findings	Quality assessment
Guzman-Parra et al [21]; Spain, Sweden	2020	1086 MCI[a] and dementia patient-caregiver dyads	Ad hoc-developed questionnaire to assess use and familiarity with touchscreen mHealth[b] technology (TechPH questionnaire [22])	Low technophilia in patients, young, male, highly educated, living with children, having better mental health	High quality (NIH[c] Study QA[d] Tool Score=75%)
Jacobs et al [23]; US	2021	68 MCI patients 121 ADD[e] patients	Ad hoc-developed web survey	Higher willingness to remote cognitive testing in MCI; significantly less access to video chat–capable technology in ADD; old age and low educational level influence access to technology and willingness to participate in remote cognitive assessment	High quality (NIH Study QA Tool Score=70%)
Christiansen et al [24]; Belgium, Spain, Sweden	2021	1082 MCI patients	Ad hoc-developed questionnaire to assess user experience with mHealth technology	Good to excellent QoL[f] in participants with moderately or high technical skills; variation in technical skills and internet use was a relevant obstacle	High quality (NIH Study QA Tool Score=70%)
Wójcik et al [25]; Poland	2021	102 ADD caregivers	Ad hoc-developed questionnaires to assess acceptance of mHealth technology and laptop/PC use	Age, gender, and education level impact on technology acceptance; old age impact on computer but not on smartphone use; digital technology was perceived as useful for daily caring (locomotion, toileting, and meals)	High quality (NIH Study QA Tool Score=80%)
Albers et al [26]; US	2022	20 people with mild-to-moderate memory complaints patient-caregiver dyads	Semistructured interviews on digital technology use pre- and post-COVID-19 pandemic, adoption of digital technology during the pandemic, facilitators, and barriers to digital technology adoption	Technology use may benefit on maintaining social connections, alleviating boredom, and fostering caregiver relief; patient dependence and low technological literacy prevented the use of digital technology	High quality (NIH Study QA Tool Score=70%)
Talbot and Briggs [27]; UK	2022	19 ADD, mixed and related dementia patients	Semistructured interviews on digital technology use and experience during the COVID-19 pandemic	Low usability and cognitive fatigue in the use of digital technologies; need for training on the use and for a better engagement	Middle quality (NIH Study QA Tool Score=60%)
Nguyen et al [28]; US	2022	124 ADD and related dementia caregivers	Ad hoc-developed web survey to assess experience with iN2L Samsung Galaxy Tablet	Benefit on caregiver wellbeing, alleviating stress, increasing satisfaction, and improving access to supportive programs	Middle quality (NIH Study QA Tool Score=64%)

Authors and country	Year	Sample	Measurements (qualitative/quantitative)	Study findings	Quality assessment
Wilson et al [29]; UK	2023	29 MCI, ADD and related dementia patient-caregiver dyads	Videoconferencing or phone interviews of mhealth technology use	Smart devices are valuable, versatile tools for essential and meaningful activities, and necessary devices to participate in modern life; need for training on the use of smart devices	Middle quality (NIH Study QA Tool Score=50%)

[a]MCI: Mild cognitive impairment.

[b]mHealth: mobile health.

Evidence From Papers Reporting Knowledge, Familiarity, and Competence With Digital Technology

Among studies investigating factors affecting knowledge, familiarity, and competence in digital mobile health (mHealth) technology use [21,23-29], the degree of cognitive impairment was the first factor significantly affecting digital competence in the adoption of technology solutions. Individuals with milder cognitive deficits showed higher competence in the use of digital devices and the internet and consequently, greater willingness levels to participate in studies compared to those with more advanced cognitive decline [23,24]. Overall, users exhibited greater openness to digital technology when they had prior experience and familiarity and good digital literacy [21,23,24]. Significant challenges were reported in studies related to limited technical skills of both patients and caregivers [26-28]. Nonetheless, while overall caregivers showed greater competence and enthusiasm for digital technology than patients, other factors, as male sex, higher education, and younger age, impact at the individual level on familiarity and willingness to participate to studies [21,25].

Whereas smartphone acceptance is consistent across age groups, computer use declined with age and in patients versus caregivers, indicating an age-related barrier to some technologies [27-29]. For example, the use of tablets represented a significant barrier in the VITAL at Home project [28], in which caregivers required substantial guidance to effectively use the software implemented in tablets.

Evidence From Papers Reporting Acceptability and Usability of Digital Solutions

Studies examining the use of digital solutions among AD patients and caregivers [30,31,33-38,40,41] consistently found that IT system accessibility and ease of use of the proposed solution are crucial factors influencing adoption rates. Ease of use of the digital health solutions and attitude to technology represent key factors enhancing acceptance of digital tools in daily routines [30,31,33,35,37,40]. The likelihood of sustained use is related to the timing of their adoption within the disease course, with earlier implementation correlating with better long-term engagement for both patients and caregivers [34,36]. The provision of informal support and training is another enabling factor ensuring long-term and better use [31,36,41]. As the disease progresses, the severity of cognitive decline and the perceived cognitive workload pose relevant challenges for constant engagement and use [31,37,38].

Discussion

Digital technology in dementia is an area of rapid development marked by diverse approaches across countries. A huge step forward has been made during the COVID-19 pandemic, acting as a catalyst for extensive research and development of eHealth

and mHealth solutions, favoring the testing of digital solutions in memory clinics and promoting their implementation in practice [2,4,42]. In this study, we reviewed the existing literature on digital competence, attitude to technology, and use of digital tools in AD, with the final aim to underline main factors affecting the adoption of digital solutions and provide useful information for their future development and use in memory clinics.

Literature evidence revealed several barriers in adopting digital technology in dementia. Among the main factors, the severity of cognitive deficits is the first key element. As adherence to digital technology interventions decreases with the severity of cognitive decline [23,24,31,37,38], clinicians and researchers should embrace technology-based solutions at an earlier stage of the care pathway with the aim to improve use and effectiveness. With the progression of the disease, poor verbal and motor initiative may affect patient engagement with digital technology, reducing interest, initiative, and participation [27]. In such cases, behavioral or sensory-based interventions, such as sensory stimulation delivered through digital devices, represent an appropriate choice. Therefore, an in-depth assessment of the behavioral and cognitive profile should always guide the specialist to choose the right digital tool to use and address patients accordingly.

Age, digital literacy, and special needs (eg, visual or auditory impairments) are additional variables that limit the access or use of digital technology both for patients and caregivers, without affecting the will to participate in telecare services [21,25,43]. These aspects are of particular relevance in memory clinics, where final users are often patients and caregivers in old adulthood [44]. The type of digital device may also impact the feasibility and real-life implementation of digital protocols, with smartphones being more accessible compared to computers or other devices [27,29,30]. Consequently, smartphones show higher acceptability scores in patients [45,46], although some challenges in the use of touchscreen and software updates are reported, particularly among those with poor digital literacy and visual impairments [24].

Another crucial barrier to the stable use of eHealth and mHealth solutions is the need for training and support [27,29,30,34,36]. The availability of formal support in the technology setup or training has been shown to positively impact willingness and acceptability [30,34,41]. As individuals may be unlikely to embrace burdensome technologies [26], preliminary training at health care facilities before the in-home adoption should be recommended to overcome potential technophobia in patients and caregivers [13,21]. The evaluation of specific digital needs in each single patient-caregiver dyad may guarantee a more inclusive and practical approach.

Therefore, the lack of active involvement of final users in the design, development, and testing of novel digital solutions crucially contributes to the poor applicability of these instruments in real-life scenarios [47].

In addition, developing technologies without user burden is pivotal for their success. Minimizing the burden on caregivers is of paramount importance, as they are often responsible for managing digital tools (eg, calendars for medication or televisits). The mitigation of stress and anxiety due to the use of technologies is crucial for caregivers [26,35,37,38], particularly for those individuals with disadvantageous socioeconomical backgrounds, who face additional challenges in adapting to the tools and using them effectively [35]. Co-design with end-users and adaptation of the digital tool to real-life needs are therefore critical [47].

Several limitations characterize the body of research analyzed in this review. Many studies involved small sample sizes that were not fully representative of the AD population, often excluding individuals who were unable or unwilling to participate for various reasons. Availability of high-speed internet connection [23,24], recruitment or screening modality (eg, through email, social media or videoconference) [26,27], and socioeconomic status of participants [23,37] are additional variables affecting results, while study design (eg, lack of control group or randomized approach [28]) and measurement issues (eg, lack of pre-post measures [36]) are crucial aspects that hamper the reliability of data findings.

In conclusion, digital tools have the potential to significantly influence the quality of dementia services acting on different dimensions [13]. They can increase effectiveness by enabling faster access to specialist care, better diagnoses and treatments, and preventing avoidable hospitalizations. They improve timeliness, reducing waiting lists and unnecessary travel. They ensure patient-centeredness and safe care, providing care tailored to individual needs and values and treating patients more appropriately. They provide integrated, more efficient, and equitable care by taking an interdisciplinary approach involving multiple specialists, improving cost-effectiveness, and overcoming geographic barriers addressing cultural diversity. However, the adoption of digital technology is limited by many patient-related barriers. Improving digital competence in the patient-caregiver dyads and implementing a systematic patient-oriented strategy for the development and use of digital tools (eg, by promoting participated design, early timing of solution adoption and availability of training and technical support) remain critical factors to consider for the successful incorporation of digital eHealth and mHealth solutions and services into future memory clinics.

Abstract

Background: In the past decade, the use of digital or electronic records in social care has risen worldwide, capturing key information for service delivery. The COVID-19 pandemic accelerated digitization in health and social care. For example, the UK government created a fund specifically for adult social care provider organizations to adopt digital social care records. These developments offer valuable learning opportunities for implementing digital care records in adult social care settings.

Objective: This rapid scoping review aimed to understand what is known about the implementation of digital care records in adult social care and how implementation varies across use cases, settings, and broader contexts.

Methods: A scoping review methodology was used, with amendments made to enable a rapid review. Comprehensive searches based on the concepts of digital care records, social care, and interoperability were conducted across the MEDLINE, EmCare, Web of Science Core Collection, HMIC Health Management Information Consortium, Social Policy and Practice, and Social Services Abstracts databases. Studies published between 2018 and 2023 in English were included. One reviewer screened titles and abstracts, while 2 reviewers extracted data. Thematic analysis mapped findings against the nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) framework.

Results: Our search identified 2499 references. After screening titles and abstracts, 71 records were selected for full-text review, resulting in 31 references from 29 studies. Studies originated from 11 countries, including 1 multicountry study, with the United Kingdom being the most represented (10/29, 34%). Studies were most often conducted in nursing homes or facilities (7/29, 24%) with older people as the target population (6/29, 21%). Health records were the most investigated record type (12/29, 41%). We identified 45 facilitators and 102 barriers to digital care record implementation across 28 studies, spanning 6 of the 7 NASSS framework domains and aligning with 5 overarching themes that require greater active management regarding implementation. Intended or actual implementation outcomes were reported in 17 (59%) of the 29 studies.

Conclusions: The findings suggest that implementation is complex due to a lack of consensus on what digital care records and expected outcomes and impacts should look like. The literature often lacks clear definitions and robust study designs. To be successful, implementation should consider complexity, while studies should use robust frameworks and mixed methods or quantitative designs where appropriate. Future research should define the target population, gather data on carer or service user experiences, and focus on digital care records specifically used in social care.

Introduction

Background

The demand for adult social care is vast. Global demographic changes throughout the 20th century have led to substantial population aging, decreased mortality and communicable diseases, and increased chronic noncommunicable diseases. Consequently, more adults and older people have long-term care needs, particularly in high-income countries where the epidemiological transition began earlier [1]. Technology has been proposed to help manage this increasing demand in health and social care by improving efficiency, care quality, and effectiveness [2-4]. Digital care records are one such innovation in adult social care.

In this paper, adult social care refers to long-term, aged, or disability care, including care homes; support in the home; domiciliary care (eg, personal care, practical tasks, and crisis support); community-based support such as inclusive arts programs; and social relationships that aim to keep people independent, active, and living well.

The use of digital care records has increased across various adult social care settings and countries since 2012 [5]. These records capture key information for service delivery, including individuals' characteristics, the care they receive, and how they respond to it. They monitor service users and track service delivery, supporting care planning, medication, and assessments [6-10]. In addition, they serve administrative purposes [8,11,12], support compliance with data documentation regulations [13], and inform care delivery decisions [14,15]. Different terms are used to describe digital care records in social care. In the United Kingdom, the term digital social care records (DSCRs) is common. In North America, parts of Europe, and Australia, terms such as electronic health records [16-20], electronic patient records [6], or electronic medical records [9,19] are often used. Digital care records can be part of health information exchange initiatives, which facilitate data sharing across health and social care to improve care continuity and efficiency [16-20].

Despite the increasing use of digital care records, much of the existing literature focuses on their implementation in nursing homes or approaches the topic from a social work perspective, failing to capture the full scope of adult social care. One systematic review of electronic health records identified that health information exchange is facilitated by workflow integration and flexible organizational culture and impeded by incomplete data, inefficiency, and unfavorable market conditions [21]. Another review found that electronic health records support health outcomes, clinical documentation management, and decision-making [2]. To the best of our knowledge, the only previous review of DSCRs that looked at the benefits of implementation was a review by Greenstock [22]. This literature review highlighted improved documentation and health outcomes as well as increased collaboration and communication, efficiency, quality of care, client or family involvement, and risk management [22]. It identified less evidence regarding financial benefits and increased workforce satisfaction [22]. It is unclear how many benefits were realized versus anticipated [22]. A scoping review of electronic information systems in social care found that they can negatively affect social workers' priorities and do not meet sector needs [23].

These reviews predate the COVID-19 pandemic, which accelerated digital system development in health and social care [24]. For example, the UK government injected funds during the COVID-19 pandemic to drive digitization and has since continued these efforts. A specific fund for adult social care provider organizations supports DSCR adoption, with the most recent government target of 80% adoption across adult social care provider organizations in England by March 2025.

Objectives

The intensity of the activity discussed above presented an opportunity to learn about DSCR implementation and impact through evaluation. Considering recent developments, this rapid scoping review sought to assess what is known about DSCR implementation in adult social care settings and identify evidence gaps to inform a rapid evaluation of DSCR implementation. While this purpose has influenced decisions around the methods, such as a rapid approach and more intensive searching for UK literature, the review considers the international literature on DSCR implementation and draws out implications for an international audience.

We mapped our findings against the nonadoption, abandonment, scale-up, spread, and sustainability (NASSS) framework by Greenhalgh et al [25]. Designed in 2017 as an evidence-based, theory-informed, and pragmatic tool, it helps predict and evaluate the success of technology-supported health or social care programs. As it focuses on adoption, nonadoption, and abandonment of technologies as well as the challenges associated with the scale-up, spread, and maintenance of digital systems, it was deemed appropriate for capturing the field's complexity. The framework was particularly useful during data analysis. Most of the literature retrieved identified large numbers of facilitators of and barriers to DSCR adoption. The NASSS framework helped to position these within an interrelated system and organize them in a way that could provide guidance in areas requiring active management of complexity. As the NASSS framework has been applied more often to health care settings, this review was also an opportunity to explore its value for technology adoption in social care.

Methods

Overview

The rapid scoping review followed the 6-stage framework outlined by Arksey and O'Malley [26], which was later refined by Levac et al [27] and the Joanna Briggs Institute [28]. Following the study by Tricco et al [29], we made some amendments to enable a rapid review. The review is reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for

Scoping Reviews) guidelines (Multimedia Appendix 1) [30]. The search strategy is reported in accordance with the PRISMA-S (Preferred Reporting Items for Systematic reviews and Meta-Analyses literature search extension) checklist [31]. A protocol for this review was developed using the PRISMA-ScR and registered prospectively with the Open Science Framework on August 9, 2023 [32].

Identifying the Research Question

We used the Joanna Briggs Institute's population, concept, and context framework [28] to formulate the following scoping review questions: (1) What is known about the implementation of DSCRs in social care settings? and (2) How does implementation vary across use cases, social care settings, and the broader context? The subquestions were as follows:

- What DSCR is being used?
- What situation or setting is the DSCR being used in, and which actors are involved?
- What is the broader context within which DSCRs are being implemented or used?
- What is the use case for the DSCR, and what are the intended outcomes and benefits?
- How has the implementation of DSCRs been evaluated or researched, and what theoretical framings have been used?
- What are the intended or actual outcomes and benefits of DSCR implementation?
- What helps or gets in the way of the implementation of DSCRs?

Identifying Relevant Studies

A librarian with experience in undertaking reviews (KP) designed the search in consultation with the research team. The search was undertaken between August 2, 2023, and August 11, 2023, by 2 librarians (KP and SDG) across MEDLINE (through Ovid; KP), EmCare (through Ovid; SDG), Web of Science Core Collection (Clarivate; KP), HMIC Health Management Information Consortium (through Ovid; KP), Social Policy and Practice (through Ovid; KP), and Social Services Abstracts (through ProQuest; SDG) databases.

The search strategy used 3 concepts: digital care records, social care, and interoperability. These concepts were combined in the search string as (Digital Care Records AND Social Care) OR (Social Care AND Interoperability). The interoperability concept was included, as it is central to policy narratives surrounding the implementation of DSCRs in England, with expectations that DSCRs will facilitate data sharing with general practitioners and hospitals. The initial search strategy was developed on MEDLINE (Ovid) by one of the librarians (KP) and run in each database by KP and SDG. Publications were limited to those published in or after 2018 until 2023. The results were limited to the English language. The databases were searched using keywords and controlled vocabulary (eg, Medical Subject Headings or Emtree) where appropriate and adapted according to the requirements of each database. The full search strategy for each database can be found in Multimedia Appendix 2.

There were 3466 results in total. The results were exported to EndNote (Clarivate), and 993 duplicates were removed following a structured process [33], leaving 2473 unique results. These were exported as a research information systems file to Covidence (Veritas Health Innovation Ltd) software [34] for title and abstract screening as well as for full-text review.

In addition, given the intention of informing an evaluation in the context of the English language, we searched key English websites to capture gray literature not identified through the databases. The chosen websites were the Local Government Association [35]; King's Fund [36]; Social Care Institute of Excellence [37]; Centre for Care [38]; Digital Care Hub, formerly Digital Social Care [39]; and TEC Service Association [40]. Searches were also performed on Google, and we contacted experts identified through the review. From these searches and reference checking, 27 references were identified. Of these 27 references, 1 (4%) duplicate was removed, and 1 (4%) reference that reported results from a study already included was merged with the main reference. One reference recommended by an expert was also included. This resulted in 26 references retrieved through our gray literature search.

Study Selection

We included studies that (1) took place within adult social care settings; (2) involved the implementation of a DSCR, which may be referred to by other labels, such as electronic care records and electronic information systems; (3) were carried out using any study design (eg, experimental, quasi-experimental, and observational, including quantitative and qualitative studies); and (4) were published from 2018 onward. This decision was made on the basis that existing reviews have captured the literature on DSCRs up until the end of 2017.

Following rapid review methodology guidance [29,41], all references retrieved from our search were screened by a reviewer with expertise in systematic reviews (WSR). Initial screening was based on titles and abstracts. References were selected for full-text review if they met our inclusion criteria or if it was unclear that they did. The same reviewer (WSR) performed the full-text review. A second reviewer, who is an expert in adult social care research (JM), cross-checked references that were excluded in this phase. Disagreement was discussed until a consensus was reached.

Charting the Data

A data extraction template was developed by the team using Excel (Microsoft Corp). The form included key characteristics of included studies, such as the population, concept, context, study design, and methods, and key findings that were relevant to the review questions. In total, 2 reviewers (MS and WSR) performed the data extraction. Due to the heterogeneity of studies and following best practice, the extraction form was piloted and iteratively adapted through discussions between the 2 reviewers and a third reviewer (JM), who oversaw the extraction process.

During the data extraction, we discovered that 2 publications [42,43] reported results from the same study. Another publication [44] was a preprint version of 1 peer-reviewed article [45], which was also included in the review. All publications were included to ensure we used the information available, but

to avoid duplication of information, we extracted information at the study level rather than the publication level.

Collating, Reporting, and Summarizing the Results

There were several steps involved in collating and reporting the results. We first created a summary of the included studies, categorizing the papers according to relevant study characteristics, such as study design, population, context, methods of data collection and analysis, and theoretical perspectives. We then worked inductively to identify intended or actualized benefits and outcomes and barriers to and facilitators of implementation raised in the papers. Using thematic analysis, we compiled a descriptive overview of the unique barriers and facilitators identified in the papers, including frequency distributions.

We then used the NASSS framework as a sensitizing framework and worked deductively to ensure we had not missed anything of relevance to the NASSS domains. In this process, further barriers and facilitators were identified, and these were mapped alongside those identified from the inductive process to the NASSS domains and subdomains. Where a category was associated with >1 NASSS domain, it was mapped against the domain perceived as most affected.

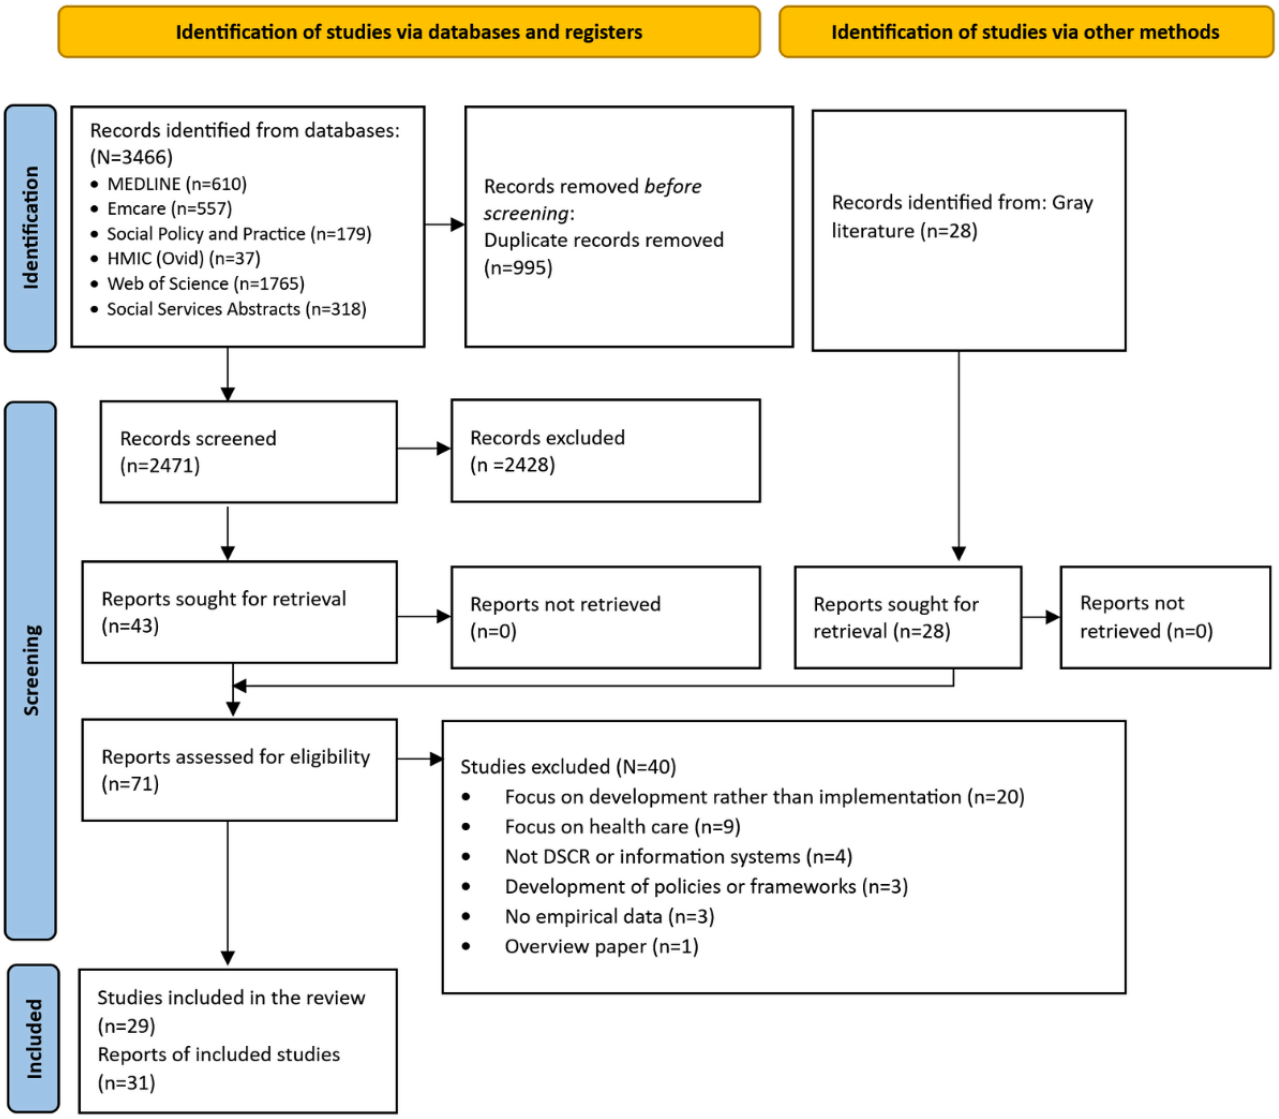
To synthesize our findings, we then grouped the barriers and facilitators into themes capturing complex aspects of the adoption process. Complexity was determined using the NASSS framework, which defines implementation as simple (ie, few components and predictable), complicated (ie, many components but still largely predictable), or complex (ie, many components interacting in a dynamic and unpredictable way) [46]. The more complexity there is in the system, the less likely the technology is to achieve sustained adoption across the system, and the more likely it is to be abandoned [46]. The themes draw attention to areas that require greater active management with respect to implementation [25].

Results

Overview

Our search resulted in 2471 references after duplicates were removed. An additional 28 references were identified through the gray literature search, resulting in 2499 references. After screening references based on titles and abstracts, 71 records were selected for full-text review, of which 31 references were included from 29 different studies (ie, 2 pairs of papers reported on the same studies). The article selection process and reasons for exclusion are presented in Figure 1 [47].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flowchart. DSCR: digital social care record.



Study Characteristics

As Table 1 presents, of the 29 studies, 10 (34%) were conducted in the United Kingdom—7 (24%) in England [3,7,10,20,48-50], 2 (7%) in Scotland [43,45], and 1 (3%) [51] in multiple UK countries. Of the 29 studies, 5 (17%) were conducted in the United States [9,14-16,18], 3 (10%) in Finland [52-54], 2 (7%) in Australia [11,13], 2 (7%) in Canada [19,55], and 2 (7%) in Sweden [12,56]. The remaining studies were conducted in Switzerland [8], Japan [57], Austria [17], and Italy [58] or involved multiple countries [6].

Studies in the United Kingdom were conducted in care homes (3/29, 10%) [43,45,48], health and social care provider organizations (4/29, 14%) [3,7,20,49], multiple social care settings (1/29, 3%) [51], councils (1/29, 3%) [50], and a continuing health care team (1/29, 3%) [10]. More than one-third of studies from other countries were conducted in nursing homes and facilities (7/29, 24%) [6,8,9,14,15,17,18]. Other settings included home care (5/29, 17%) [12,55-58], care homes (1/29, 3%) [13], long-term care facilities (1/29, 3%) [11], an acute care hospital and its neighboring long-term care home (1/29, 3%) [19], assisted living communities (1/29, 3%) [16], health centers in Finland (2/29, 7%) [52,53], and social care services (1/29, 3%) [54].

[a]DSCR: digital social care record.

[b]Total is >100% because some studies collected information with different types of informants.

Studies investigated several different types of digital care records—from health information technology in general (4/29, 14%) [18,48,55,57] to electronic medical records or electronic health records specifically (12/29, 41%) [6,8,9,11,12,14-18,53,56]. Some were specific systems commissioned by or developed for care providers, local authorities, or regions, such as the aged care ecosystem [13], the Edotto regional information system [58], CareFirst [10], the PASSsystem [51], or CareCentric [3], among others. Of the 29 studies, 4 (14%) focused on interoperability [10,19,20,57]. Studies can be grouped into those which aimed to (1) identify barriers or facilitators to the implementation of DSCRs and information exchange systems (9/29, 31%) [3,10,13,19,20,48-50,53], (2) assess the proportion and prevalence of services using DSCRs and information exchange systems and how these are being used (7/29, 24%) [14-18,45,56], (3) investigate how digital systems affect the work of care professionals or care providers (4/29, 14%) [7,11,51,54], (4) assess care professionals' perceptions about the use of digital systems (4/29, 14%) [6,8,52,55], (5) map services' readiness or maturity and care professionals' capability to adopt DSCRs and information exchange systems (3/29, 10%) [9,12,42], (6) assess potential strategies to improving existing DSCRs or information exchange systems (1/29, 3%) [58], and (7) assess the impact of use of information communication technology (ICT) on health outcomes (1/29, 3%) [57].

To achieve these aims, most studies used a qualitative design (14/29, 48%) [3,6,7,11-13,17,48-50,52,53,56,58]. Of the 29 studies, 8 (28%) used mixed methods [9,10,19,20,45,51,54,55] and 7 (24%) used a quantitative design [8,14-16,18,43,57]. None of the studies that aimed to identify barriers or facilitators, to investigate how digital systems affect work routines, or to assess potential strategies to improve digital systems used quantitative methods. Among the studies that aimed to assess professionals' perceptions of digital systems, only 1 was quantitative [8]. Of

the studies that aimed to assess the proportion and prevalence of digital systems, most (4/29, 14%) used quantitative methods [14-16,18]. The study assessing the impact of ICT on health outcomes was also quantitative [57]. The studies that aimed to map services' readiness and maturity varied between qualitative [12], quantitative [42], and mixed methods approaches [9].

Most studies (20/29, 69%) did not use a theoretical framework to interpret their results [3,8-10,14-17,19,42,45,48-52,54-57]. Of those that did, theories included normalization process theory (2/29, 7%) [20,53], sociotechnical systems theory (1/29, 3%) [6], the Nolan stage model (1/29, 3%) [18], an implementation process framework (1/29, 3%) [13], the DeLone and McLean model of information systems success and the Wang and Strong quality framework (1/29, 3%) [58], activity theory (1/29, 3%) [11], design thinking (1/29, 3%) [12], computer-supported cooperative work (1/29, 3%) [7], and the unified theory of acceptance and use of technology (1/29, 3%) [20].

A detailed list of the characteristics of all studies included in this review is provided in Multimedia Appendix 3 [3,6-20,42-45,48-58].

Summary of Facilitators of and Barriers to the Implementation of DSCRs

Overview

Of the 29 studies, 28 (97%) identified 45 facilitators of and 102 barriers to digital implementation. These were then coded into 32 categories that aligned with the NASSS framework domains: 18 contained facilitators and 24 contained barriers (the total is >32 because some categories contained both facilitators and barriers). The most frequent barriers were related to the digital system lacking interoperability, which was found in 10 of the 29 studies (34%). They also related to insufficient funding or financial incentives and high costs of implementation (9/29, 31%), and technology not matching the context of use (9/29, 31%). Most facilitators were associated with building interorganizational trust and collaborative relationships (5/29, 17%); adequate training (5/29, 17%); anticipating, frontloading, and resourcing the work required to clarify information governance (4/29, 14%); skillful leadership enhancing an organization's digital readiness and capacity for change (4/29, 14%); and high usability of the digital system (4/29, 14%).

Regarding the NASSS framework domains, most facilitators were related to the organization (24/45, 53%). This was followed by the adopter system (8/45, 18%), the technology (6/45, 13%), the value proposition (4/45, 9%), the interaction between domains and adaptation over time (2/45, 4%), and the wider context (1/45, 2%). Most barriers were also related to the organization (52/102, 51%). This was followed by the technology (25/102, 24.5%), the wider context (14/102, 13.7%), the value proposition (6/102, 5.9%), the adopter system (4/102, 3.9%), and the interaction between domains and adaptation over time (1/102, 1%). No barriers or facilitators were related to the condition domain.

The categories containing facilitators and barriers were then organized into five broad themes: (1) the legal and institutional context for holding and sharing data and its effect on the ability and willingness to share data, (2) digital readiness and organizational capacity for change, (3) using and sharing recorded information within technical constraints, (4) alignment between care practices and digital recording practices, and (5) differences between what is expected and what is achievable with digital systems.

A summary of how barriers and facilitators identified in each study were mapped to categories, themes, and the NASSS framework domains and subdomains is provided in Multimedia Appendix 4 [3,6-20,42-45,48-56,58]. The 5 themes are summarized in greater detail in the subsequent sections.

Legal and Institutional Context for Holding and Sharing Data and Its Effect on Ability and Willingness to Share Data

A key challenge to DSCR implementation involved information governance concerns about holding and sharing data. These issues arose from vague legislation, market competition, conflicting priorities, poor internal and external coordination, and low cross-organizational trust. Building trust and adequately resourcing digital change facilitated implementation.

Commercial and Regulatory Context in Which Care Providers Operate

A total of 3 studies conducted in the United Kingdom [3,42,50] identified barriers related to market competition among social care provider organizations and digital suppliers and a lack of national regulation and standards. Private sector care providers were concerned that the commercial sensitivity of data could compromise their competitive advantage [42]. Vendor lock-in also occurred, as technology suppliers hesitated to share data with other suppliers [3].

The governance and ethics framework for social care data in the United Kingdom is less developed compared to that for National Health Service (NHS) data. There is no established system for the governance of care home data, which are held by private companies, care regulators, and health and social care provider organizations [42]. This context made data sharing challenging [42]. Despite regulatory progress, councils found new national frameworks inadequate on data and interoperability standards [50].

Interorganizational Trust and Relationships

In 5 studies [3,9,42,48,49], 4 of which were UK based, a lack of trust between providers and other organizations hampered information governance and data sharing. Clinical and health care partners were particularly reluctant to share data with social care [3,9,50] due to misunderstandings about their role and concerns about sharing information with staff who were not registered social workers [50]. Ownership of a large volume of patient data and responsibility for confidentiality also fostered a risk-averse attitude among general practitioners [3].

Four studies conducted in the United Kingdom [3,42,49,50] found that building trust and collaboration between organizations facilitated implementation. Care homes were more willing to share information when they had well-established relationships with local authorities [42]. Scotland's regional "data safe havens," led by trusted partners such as the NHS, academic

institutions, and government agencies, represented a centralized approach to managing, storing, and handling access requests to health care data that encouraged relationships between health and social care provider organizations [42]. They were an example of data being handled respectfully, professionally, and securely [42]. Ambiguous governance frameworks necessitated clarifying information governance requirements and building mutual trust in systems. In the United Kingdom, local authority and provider staff needed to dedicate significant resources upfront to ensure safe data handling processes [3]. Setting up information sharing agreements that specified data flows between organizations could be intensive, involving unexpected time and effort that was often related to building relationships and engaging numerous actors with data sharing plans [3]. Undertaking this work early on in projects facilitated implementation, locating expertise and capacity, and building trust across organizations [3]. Leaders who fostered positive working relationships between decision makers facilitated shared priority setting [49], helping them to circumvent barriers stemming from organizational fragmentation [49].

Organizational Coordination to Clarify Information Governance

In 4 studies [3,9,42,49], a general lack of coordination hindered the clarification of information governance processes needed to implement digital systems. Divisions between and within organizations created siloed data systems, resulting in residents' records being stored in different systems across multiple services [49]. Poor coordination was linked to information governance professionals, who managed personal data for single organizations, lacking the capacity to handle additional responsibilities for cross-organization information governance and data sharing [3]. This issue was compounded by provider leaders' lack of understanding of information governance [3].

Lack of a shared, standardized understanding of information governance and data ownership across organizations also created confusion among staff. Nursing home leaders in the United States [9], for example, raised concerns about transparency and maintaining control of residents' health data that were viewed as belonging to the patients, leading to fear of lawsuits regarding data sharing [9]. In the United Kingdom, there was a lack of shared understanding with confusion about consent, which was related to social care and local government starting from a different position to NHS partners when it came to information sharing [50].

While a lack of organizational coordination was a barrier to implementation, 4 studies [3,10,49,58] identified that prioritizing and adequately resourcing the work required to define information governance was a facilitator to data sharing and in turn improved service quality. In the implementation of information systems across home care services in Italy [58], agreements could be reached on hardware and software once information governance had been properly defined. The synergies resulting from integrating information systems from different organizations then positively affected service quality. In another study, health and social care managers also acknowledged that undertaking considerable work together to agree on what could be shared helped to implement a shared electronic record between nursing and adult social care practitioners [10]. While fostering cross-organizational relationships was important, substantial resources were required to develop and sustain these relationships [49].

Digital Readiness and Organizational Capacity for Change

The importance of investing in the necessary groundwork and anticipating the work involved in digital implementation is linked to an organization's digital readiness and capacity for new technology more generally. Facilitators and barriers within this theme were related to hardware and internet connectivity issues, funding issues in the sector, organizational infrastructure, and resourcing the work required for digital change, including leadership and training.

Hardware and Internet Connectivity Issues

Hardware issues hindered implementation in 4 studies [6,8,11,55] and negatively impacted care quality in 2 studies [6,11]. Problems included a lack of computers and handheld devices for timely patient data documentation in nursing homes [6,8], ergonomic challenges in home care [55], and poor battery lives on portable devices in home care [11,55]. In Australia, residential aged care nurses and care workers relied on memory when portable devices ran out of battery during medication rounds, reducing patient safety [11]. Sharing limited devices in nursing homes also delayed access to updated care plans in a cross-country nursing home study [6]. Hardware issues implied a failure to commit the upfront investment needed to install the hardware required to successfully implement digital systems, reflecting a lack of organizational capacity and readiness [11,55]. Internet connectivity issues were identified as barriers in 5 studies [13,42,48,55,56]. Reliable internet was often deemed essential for digital implementation, and poor connectivity indicated insufficient organizational resources. This was problematic in home care, where mobile internet access was inconsistent [55,56], and in care homes with poor Wi-Fi in old buildings [13,48]. For instance, 18% of care homes in a southeast Scotland project experienced regular internet interruption, and 27% of care homes had limited internet access [42].

Funding Issues in the Sector

In total, 9 studies [3,9,14,16,18,48-50,56] identified insufficient funding or financial incentives and high costs as barriers. Four studies were conducted in the United States [9,14,16,18], 4 studies were conducted in England [3,48-50], and 1 study was conducted in Sweden [56]. In England, short-term funding pushed organizations toward unambitious digital solutions [3]. The financial pressures often forced providers to adopt a short-term view on the finances needed to implement and sustain digital records, constraining the scale of change and preventing it from being embedded [3]. Where funding was available, finding, requesting, and receiving it was not always straightforward [48]. Small care homes in England faced issues such as poor communication from funders, complicated application procedures, and delays in receiving funds [48].

Organizational Infrastructure and Resourcing the Work Required for Digital Change

Barriers related to organizational infrastructure were noted in 5 studies [19,20,48,49,56]. Issues included insufficient ICT and human resources staff [48,56], high senior staff turnover [49], poor internal communication that left staff unaware of implementation [19,20], and inadequate leadership [20]. One English study [3] highlighted that successful implementation required clear planning and resource allocation; for example, phased deployment of resources demonstrated providers' competence in managing digital change, making it easier for them to secure further funding [3].

Four studies [3,10,50,53], 3 of which were conducted in England, noted the importance of skillful leadership in enhancing digital readiness. Identifying leaders with the right skills was crucial for managing large-scale digital projects [3]. The type of leadership required depended on context, with some providers preferring leaders who could balance risk and reward in deploying resources, while others sought leaders who were respected by their peers to help foster engagement among staff [3]. Senior staff functioning as "change agents" also motivated practitioners to review their practices [10]. Successful councils had strong leadership support for digital initiatives [50]. In England, councils successful in implementing data standards and interoperability had strong leadership support [50], with directors of social care, chief information officers, and elected members all prioritizing digital working and integrated care [50].

Adequate Training

Absent or inadequate training was a barrier in 4 studies [6,19,20,48]. Issues included a lack of tailored training [20] and inappropriate content [19]. Conversely, 5 studies identified high-quality training as a facilitator [3,6,11,49,53]. One multicountry study identified both facilitators and barriers across the different contexts [6]. Effective training was tailored to practitioners' skills and tasks [6,53] and included on-the-job and context-specific training [6], ongoing sessions [55], follow-up visits [53], and continued onsite support from suppliers [6,11]. High-quality training that was tailored, targeted, and practical aligned care practices with the new practices required by digital systems.

Using and Sharing Recorded Information Within Technical Constraints

This theme included issues with technical interoperability of digital systems, their level of usability and user-friendliness, and the extent to which they had been appropriately adapted for social care from other settings, which were often acute or primary care.

Interoperability

Interoperability is understood as a technology's capacity to electronically share patient information between different systems and to use the information that has been shared [59]. Lack of interoperability was identified in 10 studies as a barrier to sharing recorded information [3,6,9,15,17,42,49,50,52,54], being reported by 57% of 491 respondents in the US [15] nursing facilities with electronic health records. Care professionals and managers in Finland [52] and senior health and care leaders in England [49] also criticized information systems for not always "communicating" with each other. While providers were adopting digital solutions, these were not necessarily increasing interoperability and risked creating new data silos [15].

In some studies, interoperability barriers were attributed to the multitude of systems used by different organizations. Across 9 nursing homes in Austria [17], managers exchanged information with at least 18 other organizations, most of which were not part of the same electronic health record system. In the United States, while 95.1% (775/815) of nursing homes had electronic medical records, only 45.8% (373/815) had some capability for information exchange with other organizations. The variety and sheer number of systems used by different providers was a concern for 8 (67%) out of 12 staff members in subsequent interviews [9].

In England [50], interoperability issues presented as systems being unable to store identification data such as the NHS number. However, local authorities were often unaware, at the procurement stage, of which digital options could store such information. There was also confusion among councils and suppliers about the possibilities and limitations of NHS number tracing. This was linked to low organizational readiness and capacity, with providers not knowing which technological features they needed when choosing a system [50]. It also related to the downstream value suppliers promised providers in terms of being transparent about what their products could offer [50].

Staff in all 3 nursing homes in a multicountry study also complained that the electronic patient records lacked interoperability and options to adjust features to meet specific needs. This implied a contradiction between customizability and interoperability, with customizable systems more likely to meet care provider needs but less likely to be compatible with other systems than off-the-shelf technology [6].

Usability and User-Friendliness

A total of 8 studies [6,11,12,51,52,54-56] reported barriers related to this theme, 3 of which [52,54,56] were based in Nordic countries. These barriers were more closely associated with using, rather than sharing, recorded information within technical constraints.

A total of 4 studies [51,52,54,55] found problems with the system being slow, crashing, and having unscheduled downtime. Others pointed to features that made staff work routines more inefficient, such as the example from US home care nurses needing to click 22 times to get into each individual's medical record, a cumbersome process that had to start again when they moved on to the next patient [12]. In a multicountry study, care home staff disliked being forced to enter narrative text into the electronic patient record and preferred drop-down menus [6]. An inefficient information retrieval process within an Australian electronic Health record system meant that staff in long-term care facilities had to perform lengthy manual searches to identify wound charts, with the system also failing to alert them if they were duplicating charts that already existed [11].

In 5 studies [8,11,13,20,55], the high usability and usefulness of digital systems facilitated implementation. In 3 cases [13,20,55], systems offered easy access to information, improving the immediacy of care provision and documentation. In some instances, they enhanced the accuracy of care documentation through better information visibility [13,55] or by automating tasks that were previously manual and prone to human error [11]. Digital systems with flagging features also supported resource prioritization and management decisions [13]. These facilitators aided implementation by increasing task efficiency and supporting the knowledge generated or made visible by the technology, thereby improving data accuracy and decision-making.

Adapting Technology From Other Settings

Barriers in 5 studies [6,20,45,54,56] were related to digital systems that had been maladapted from other settings and were consequently deemed inappropriate for social care. In England, social care workers were less likely to perceive health information exchange systems as useful compared to health care workers and experienced issues with the user interface [20]. Staff noted that the system looked unfamiliar compared to other systems they used, as the health information exchange was primarily designed for acute and primary care settings, with little consideration given to social and community services [20].

An Australian study [13] reported successful adaptation of a digital system originally designed for an acute hospital setting to a care home involving staff at all levels, residents, and their relatives that helped to make the product appropriate for the care home setting [13]. This co-designed process facilitated implementation and increased the likelihood of success.

Alignment Between Care Practices and Digital Recording Practices

Overview

Barriers related to digital systems not matching the context of use were identified in 9 studies [3,6,7,12,45,50,54-56]. These barriers referred to misalignments between care practices within the social care sector and recording practices demanded by new digital systems. They included reduced interactions between clients and practitioners, conflicts with preferred data input methods, and exacerbation of existing organizational issues. Staff perceptions of improved care quality increased the likelihood of accepting the technology.

Care Quality and the Relational Nature of Social Care

A total of 5 studies [6,7,9,49,52] highlighted barriers where digital systems decreased the relational nature of social care. Problems arose when care staff experienced disruption to their relational work and viewed the technology as depersonalizing care. In Finland, new information systems increased technical tasks at the expense of relational tasks performed physically close to clients [52]. In England, digital records influenced the nature of the clinical encounter for occupational therapists. By focusing on data collection and adherence to standard procedures, they reduced opportunities for building rapport with clients [7]. Concerns also existed that technology use close to clients was intrusive and reduced care quality [6,55]. Defining the problem as a preference for “high touch” over “high tech,” a US study found that 5 out of 12 nursing home leaders feared that technology might detract from the personal experience they aimed to provide [9].

Technological features, such as prescriptive data fields, also imposed work routines that prioritized clinical data and processes. In a Scottish study, data systems in care homes promoted a task-oriented culture over resident-focused care [45]. Prescripted data fields limited the recording of social and emotional activities and care provision, leading to an overly clinical focus in the data [45].

Only 1 study found that a digital system aligned well with the relational nature of social work, facilitating implementation [13]. In Australia, an aged care ecosystem that was co-designed with staff and residents allowed care workers to multitask and spend more time with residents. This saved time for staff and improved care quality, encouraging acceptance of the system [13]. Managers noted that the technology provided prompts for tasks such as repositioning residents, better aligning care with resident needs [13]. In England, 2 studies found that perceived care quality improvements increased staff acceptance of digital systems [3,20]. Demonstrating the technology’s value to different professionals helped staff “buy into” digital change [3]. Administrative staff adopted technology for time-saving benefits, while practitioners focused on its impact on care [3]. Perceived improvements to patient safety also increased the likelihood of adopting digital systems [20].

Preexisting Organizational Problems

A total of 2 studies [12,19] identified barriers where digital systems exacerbated preexisting organizational problems, such as the numerous communication channels in home care organizations [12]. The lack of standardization required nurses to adapt to various communication methods, for example, contacting physicians through primary care nurses or by fax [12]. They often only discovered that their request had reached doctors through changes made to patients’ medicines [12]. Rather than standardizing processes, the new digital system added more communication channels. While this issue presented as inappropriate technology, it was rooted in inefficient work routines that predated the technology’s introduction.

Conflicts Between Data Recording Practices and Digital Systems

A total of 4 UK-based studies [3,7,42,50] identified barriers due to conflicts between data recording practices preferred by care providers and those permitted by digital systems. The lack of systematic data collection in care homes made it difficult to capture the complexity of care for individuals with multiple conditions and high support needs [42]. Frontline practitioners preferred narrative text input, while digital systems often emphasized coded data entry [3,50]. In 1 study, social workers entering free-text information sometimes included data about third parties without consent [3]. Such issues were linked to a lack of understanding about data quality in social care [50], requiring retraining on the importance of proper data collection and recording practices [3,50]. An English study found that conflicts between recording preferences and the recording permitted by digital systems were due to a mismatch between digital care records and occupational therapy concerns [7].

Therapists had to recode their interventions to fit the system's structure, suggesting that the technology did not align with sector needs, rather than indicating poor recording practices.

Differences Between What Is Expected and What Is Achievable With Digital Systems

Overview

The final theme related to the gap between organizational expectations and realistic achievements with digital systems. Guidance on available technology was often inadequate, and care providers lacked internal consensus about the technology's capabilities and what they wanted to gain from implementation. Creating a shared digital vision and adopting digital systems as part of wider cultural changes facilitated implementation.

Guidance on the Technology Available

Insufficient guidance on available technology was a barrier in 1 study in English care homes [48]. The overwhelming number of suppliers created an "unregulated tech product maze," making it difficult to choose the best option and avoid paying for unsuitable technology [48]. Care homes criticized NHS England's "assured suppliers list" of DSCR suppliers, which was introduced to aid decision-making [48]. Although suppliers on the list met a set of standards, some care homes complained that suppliers did not meet their needs and requirements, while others reported poor experiences with suppliers on the list and found themselves locked into contracts despite consistent software malfunctions [48].

A Shared Digital Vision

Creating a shared vision for collectively understanding the technology involved building organizational consensus on its potential while remaining realistic about its limitations. A total of 4 studies [3,17,20,52] found that care provider staff disagreed about the purpose of digital systems, and awareness of potential benefits for care delivery was low. There were tensions between 2 distinct staff groups with different expectations [3]. One group represented a technical and managerial culture that often initiated digital change projects and was primarily interested in the information captured by digital systems. The other was a clinical culture that was concerned with how technology could help deliver care and was more skeptical of changes to practice that lacked certain types of evidence [3]. Managers were generally more positive about implementation but lacked awareness of some of its negative effects on employees' work [52]. Staff anticipated unrealistic benefits and were often unaware of the technology's value [17,20].

A total of 2 studies found facilitators to creating a shared vision [13,53]. They highlighted the importance of co-design and inclusive implementation by gathering suggestions from staff, residents, and their relatives [13] or by conducting monitoring based on staff's feedback to system developers [53]. Involving different groups as partners in the process helped envision a digital system that benefited everyone [13]. Professionals praised comprehensive and continuous communication that helped them make sense of a new service, with information delivered through multiple channels to reach as many employees as possible, including shift workers [53].

Implementing Digital Change as a Cultural Change

Framing digital implementation as a cultural change program facilitated success in 3 studies [3,10,13]. In an Australian care home, co-designing the system, establishing a shared vision across the workforce, and providing training and feedback loops instigated a culture change that improved service delivery and problem-solving [13]. In England, barriers to scaling digital changes in health and social care were mitigated by treating them as part of a wider technology-supported clinical transformation program, rather than an ICT project [3], or as part of a larger cultural change program to improve administrative efficiency [10].

Summary of the Intended and Actual Outcomes

Outcomes of digital implementation, either intended or actual, were identified in 17 studies [7-11,13,17,19,20,48,50-52,54,55,57,58], although they were the focus of only 1 study [57]. The full details of the benefits and outcomes are provided in Table 2.

A total of 3 studies [9,17,48] identified the outcomes that participants hoped to achieve through adopting digital systems. Improved information accessibility, information sharing, and quality of care records were identified in 2 studies [17,48], making them the most frequent intended outcomes. Examples of the improved quality of records included more complete and readily available patient-related information and less documents being lost during patient transitions between different institutions [17]. Improved efficiency [17] and time savings [48] were identified as intended outcomes in 1 study.

Three studies [9,48,50], 2 of which were based in England [48,50], cited poor awareness about the benefits of digital systems for social care or concerns that they would not benefit the sector. In England, information sharing initiatives were often focused on health care and hospitals, with less attention paid to the potential benefits for councils or social care [50]. This made it difficult for social care staff and care home residents to see the benefits that digital systems could bring [48].

A total of 13 studies identified positive outcomes realized through digital record implementation [7,8,10,11,13,19,20,50-52,55,57,58]. Improved efficiency was the most frequent actual outcome (8/13, 62%) [10,11,13,19,20,50-52], achieved through the automation of previously manual processes [11], reduced duplication of procedures [20], and the increased availability [19] and immediacy [13] of information improving decision-making and care planning. These outcomes were associated with increased staff capacity [50] and productivity [52]. Impacts on efficiency were not always clear. In 1 study [11], while automatic data entry in patient records was beneficial, the system did not completely align with work processes, and staff needed to record some data twice.

Table 2. The intended and actual outcomes of digital social care record implementation (N=17).

Theme	Studies, n (%)
Intended outcomes	
Improved quality of data records	2 (12)
Improved information sharing	2 (12)
Improved information accessibility	2 (12)
Improved efficiency	1 (6)
Time savings	1 (6)
Improved care quality or planning	1 (6)
Improved communication or collaboration	1 (6)
Improved information accuracy	1 (6)
Space savings (less paper)	1 (6)
Actual outcomes	
Improved efficiency	8 (47)
Perceived time savings	7 (41)
Improved information accessibility	5 (29)
Workarounds (viewed negatively)	4 (24)
Improved communication or collaboration	3 (18)
Improved information security and risk management	3 (18)
Additional time burdens	3 (18)
Improved care quality or planning	2 (12)
Increased face-to-face work with patients	2 (12)
Improved information sharing	2 (12)
Improved information accuracy	2 (12)
Improved transparency and accountability	2 (12)
Increased staff or patient satisfaction	1 (6)
Workarounds (viewed positively)	1 (6)
Decreased communication or collaboration	1 (6)
Decreased efficiency	1 (6)
Decreased care quality	1 (6)
Decreased face-to-face work with patients	1 (6)
Lack of financial benefits	1 (6)
Rationing care documentation	1 (6)

Perceived time savings were reported in 7 studies, although the findings were not conclusive [10,13,19,20,50,52,58]. Some studies reported staff spending less time retrieving and documenting information for decision-making [13,58] and chasing other organizations for patients' whereabouts [50]. One study found time savings of up to 45 minutes for long-term care staff when completing medication reconciliation [19]. However, 2 studies found time savings in some areas and additional time burdens in others [10,52]. In 1 case, disagreements between managers and their staff arose regarding whether the digital system created time savings [52]. Managers and employees agreed that moving from phone calls to digital messaging had freed up staff time for other tasks [52]. However, employees felt that the new tasks, such as responding to clients through messages, required extra time. This additional time was not always recognized by management, nor were additional resources provided [52].

A total of 3 studies [8,13,19,20,52] found that digital systems made information more accessible. In one case, this enabled person-centered care, with easily accessible information on individual backgrounds helping staff to "see the person first and the diagnosis second" [13]. In another case, improved visibility of information facilitated medication tracking and therefore supported patient safety [19]. A total of 3 studies also highlighted improved communication and collaboration [10,52,55] and improved information security and risk management [51,52,58]. Electronic information sharing

improved partnership working, enhancing collaboration and increasing the timeliness, efficiency, and quality of care [10,52,55]. Improved information security and risk management were linked to secure information transfer and storage [51,52,58], better client monitoring [52], and increased data accuracy [51,58].

Workarounds, identified in 5 studies [7,9,11,54,55], were the most common negative outcome. Workarounds involve the implementation, by end users, of temporary practices or behaviors to overcome the limitations of a technological system [60]. Staff developed workarounds for various reasons. These included circumventing the system to share health data with residents [9] and accessing case-based information [54]. While workarounds could be beneficial [7] and support task completion [54], they also threatened data security [54].

Discussion

Principal Findings

This study investigated what is known about the implementation of digital records in adult social care settings. The literature was diverse in terms of the type of digital system, setting, and use case studied. Most of the studies used a qualitative design (14/29, 48%), particularly those looking at facilitators and barriers, how digital systems affect work routines, and potential strategies to improve digital systems. Studies were most frequently based within the United Kingdom (10/29, 34%).

Most studies focused on facilitators of and barriers to digital implementation. Many facilitators and barriers were interlinked and associated with multiple NASSS framework domains, which compounded the complexity of implementing digital systems. The 5 themes we identified using the NASSS framework are particularly complex areas that require more active management and consideration when implementing DSCRs in social care contexts.

While our findings suggest that implementing digital systems is an inherently complex process, this review did identify some strategies to manage complexity, which could constitute "good practice." In terms of digital readiness and organizational capacity for change, high-quality training was found to increase implementation success. Where training was tailored, practical, and ongoing, it helped align care practices with new practices required by the technology, thereby increasing employees' ability and willingness to adopt and continue to use the system. Although high-quality training depended on care provider leaders anticipating the financial resources needed, it seems a worthwhile investment for successful digital implementation. This finding echoes the results from a previous scoping review, which highlighted training as a key factor influencing the use of electronic information systems [23].

Implementing digital systems as part of wider cultural change projects also addressed multifaceted complexity. An example of this was the project in which implementation was co-designed with staff [13]. This approach enabled a shared vision of the technology to be created across the care home among residents and staff at different levels. The sense of ownership this instilled addressed complexity in the adopter system domain, with all users more likely to support the technology and view it as "business as usual." Co-design also addressed complexity in the technology domain, with the digital system more likely to align with the needs and practices of its user group. While incorporating digital implementation as part of broader transformation required significant resources, where there was sufficient organizational readiness and capacity for comprehensive rollout, implementation seemed to have greater potential for sustainability, scaling, and spread.

Complexity related to data sharing and information governance seemed to be more difficult to address. Trust and relationship building across organizations could help establish data sharing agreements at a localized level and therefore address complexity within the organization domain. However, fundamental barriers were associated with complexity around regulations and standards in the wider context domain, over which care providers had no direct control. Until there is primary or secondary legislative change, the governance and regulatory context will continue to impede cross-organizational data sharing efforts.

Although 17 studies identified intended or actual outcomes, they more often focused on identifying facilitators of and barriers to implementation. Improved efficiency, accuracy, and time savings were the most common positive outcomes realized through digital adoption, while workarounds and additional time burdens were the most frequently cited negative outcomes. Some of the positive outcomes reflect the results presented in the review by Greenstock [22], which also found efficiency and productivity to be a benefit of DSCRs. However, the limited detail in outcome reporting and variations in the extent to which different benefits are observed suggest that this topic would benefit from future research. Specifically, there seems to be a need for studies that quantify outcomes and pay greater attention to the necessary conditions for positive benefits to be realized.

Limitations of Studies

Most studies (20/29, 69%) lacked a clear theoretical or methodological framework. This meant it was often unclear which type of digital system or record was being implemented as well as the context, setting, and use case. While studies mentioned >100 facilitators and barriers to implementation, they did not provide any objective parameters or measures to assess how they impact implementation or social care practices. This hinders a more comprehensive comparison between the barriers and facilitators.

Some digital systems were simply described as ICT, electronic digital systems or health information technology [18,55,57], or digitalization or digital change generally [3,48,52], without definitions of these terms. Some studies appeared to use the same vocabulary to describe different systems. However, this was difficult to determine as most studies (20/29, 69%) did not specify their target population clearly. Many studies also lacked detail regarding care settings and other relevant information, which limited the possibility of performing more comprehensive comparative analysis. Future studies should pay greater attention to how they report which digital systems were implemented, the target population for the system, the setting, and the roles of the professionals involved to facilitate comparisons between

studies. Standardized reporting guidelines, such as the template for intervention description and replication checklist and guide [61], may facilitate describing digital projects or systems.

Of the 29 studies, only 2 (7%) included carers or service users as respondents, while most studies included staff (n=18, 62%) or managers (n=11, 38%). Future research may therefore benefit from incorporating the perspectives of people drawing on care to cover this gap in the literature.

Although studies included in our review mention the potential impacts of DSCRs, none provide quantifiable parameters to estimate such impacts, such as potential time savings or cost-effectiveness metrics. New studies that are appropriately designed to measure such outcomes are needed to fill this important knowledge gap in the literature on DSCR implementation.

Methodological Limitations

Due to the prevalence of qualitative designs and a lack of clear theoretical or methodological frameworks among the studies reviewed, we used the NASSS framework as a structured approach to categorizing and interpreting heterogeneous data. As this was a rapid review, the framework served as a tool to guide our data interpretation and triangulation, especially given the large number of barriers and facilitators and the varied ways these issues were described across different studies. For example, it directed our analysis of hardware and internet connectivity issues. While the studies reviewed often attributed these to technological problems, the framework enabled us to trace the associated complexity back to the organization domain, with care providers lacking the awareness, readiness, and capacity to prepare for digital implementation and adopt appropriate systems.

However, the NASSS framework carried some limitations for our analysis. No facilitators or barriers were associated with the condition domain. While the framework was developed for both health and social care, the focus of this domain on comorbidities and clinical aspects of a patient's condition may be more appropriate for health care technologies. For social care technologies, it may be more useful to approach the condition domain in terms of whether digital systems are appropriate for particular groups of clients, such as older people or people with learning disabilities, rather than specific illnesses. Alternatively, the lack of relevance of the condition domain may reflect limited attention to diversity and inclusion considerations within the studies reviewed. Another limitation of the NASSS framework was related to the final domain (ie, interaction between domains and adaptation over time). As most of the complexity we identified was multifaceted, we found it more useful to iteratively analyze the interactions between domains instead of restricting them to 1 domain. Rather than viewing complexity as belonging to separate domains, we suggest using this final domain to provide an overarching perspective of how complexity constantly intersects and interacts across domains at every stage of digital implementation.

Considering the rapid nature of this scoping review, we simplified some review procedures, such as screening and full-text assessment, which always carry the risk of missing relevant studies. To minimize such risks, all review procedures were undertaken by researchers who are experts in systematic review methods and social care research. As with every review, the choice of databases is also a limitation, as relevant studies may have been uniquely indexed in databases that were not included. However, our research was able to identify all relevant studies that were suggested by experts in the field. Moreover, we performed a comprehensive gray literature search to reduce the likelihood of missing key studies.

Despite the limitations, we believe that our review provides a comprehensive picture of the state of the literature on DSCRs. It builds on 4 previous reviews, which, when taken together, captured the literature about digital records until the end of 2017 [2,21-23]. Our review has updated and added to these findings, covering both academic and gray literature up until 2023 and using a robust theoretical framework to draw out complexity in terms of sustainability, scaling, spread, nonadoption, and abandonment of digital care records.

Conclusions

Our findings suggest that the implementation of digital care records is particularly complex due to the lack of a common language and consensus about what DSCRs should look like as well as expected outcomes and impacts. This is reflected in the scientific literature, which often lacks operationalization of key constructs and robust study designs. To be successful, implementation should consider complexity, while studies should use a robust theoretical framework and use mixed methods or quantitative designs where appropriate. We also suggest that future studies define the target population, consider gathering data on the experiences of carers and service users, and focus on digital care records specifically being used in social care, such as DSCRs.

Acknowledgments

The authors would like to acknowledge the support of the Social Care Rapid Evaluation Team coordinator Jo Ward, as well as Andra Fry, the London School of Economics and Political Science library information specialist. This study is funded by the National Institute for Health and Care Research (NIHR) Health and Social Care Delivery Research Programme (NIHR163639) as part of the Social Care Rapid Evaluation Team (NIHR153673), and open access fees were covered by the grant. The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

Data Availability

No new data were generated for this scoping review. All data were obtained from publicly available published sources and are included in this published article and its supplementary information files. We have included the search strategy in Multimedia Appendix 2, summaries of the extracted articles in Multimedia Appendix 3, and the thematic analysis process in Multimedia Appendix 4 to provide transparency on extractions and analysis.

Authors' Contributions

MS contributed to screening and data collection and was responsible for data analysis and preparation of the first draft of the manuscript. WS-R contributed to study conception and design, was responsible for screening and data collection, and contributed to data analysis and preparation of some sections of the manuscript. JM conceived and designed the research; oversaw the screening, data collection, and data analysis; and contributed to drafting of the manuscript. KP and SDG were responsible for developing and running the search strategy and drafting the paragraphs on the search methods. MB and CL contributed to the study conception and design. WS-R, JM, MB, JW, CL, NF, and NS critically reviewed the manuscript, adding important intellectual content. All authors read and approved the final version.

Abstract

Background: The implementation of eHealth applications often fails. The NASSS (nonadoption, abandonment, scale-up, spread, and sustainability) framework aims to identify complexities in eHealth applications; the more complex, the more risk of implementation failure.

Objective: This study aimed to analyze the implementation of the web-based advance care planning (ACP) program "Explore Your Preferences for Treatment and Care" using the NASSS framework.

Methods: The NASSS framework enables a systematic approach to improve the implementation of eHealth tools. It is aimed at generating a rich and situated analysis of complexities in multiple domains, based on thematic analysis of existing and newly collected data. It also aims at supporting individuals and organizations to handle these complexities. We used 6 of 7 domains of the NASSS framework (ie, condition, technology, value proposition, adopters, external context, and embedding and adaptation over time) leaving out "organization," and analyzed the multimodal dataset of a web-based ACP program, its development and evaluation, including peer-reviewed publications, notes of stakeholder group meetings, and interviews with stakeholders.

Results: This study showed that the web-based ACP program uses straightforward technology, is embedded in a well-established web-based health platform, and in general appears to generate a positive value for stakeholders. A complexity is the rather broad target population of the program. A potential complexity considers the limited insight into the extent to which health care professionals adopt the program. Awareness of the relevance of the web-based ACP program may still be improved among target populations of ACP and among health care professionals. Furthermore, the program may especially appeal to those who value individual autonomy, self-management, and an explicit and direct communicative approach.

Conclusions: Relatively few complexities were identified considering the implementation of the web-based ACP program "Explore Your Preferences for Treatment and Care." The program is evidence-based, freestanding, and well-maintained, with straightforward, well-understood technology. The program is expected to generate a positive value for different stakeholders. Complexities include the broad target population of the program and sociocultural factors. People with limited digital literacy may need support to use the program. Its uptake might be improved by increasing awareness of ACP and the program among a wider population of potential users and among health care professionals. Addressing these issues may guide future use and sustainability of the program.

(JMIR Aging 2025;8:e49507) doi:10.2196/49507

KEYWORDS

eHealth; web-based intervention; implementation; sustainability; advance care planning; NASSS framework; nonadoption, abandonment, scale-up, spread, and sustainability framework; health communication; patient education; patient-centered care

Introduction

eHealth tools can be useful for health promotion, enhancing self-management skills for people with long-term conditions, and patient-physician communication [1]. The web-based program "Explore Your Preferences for Treatment and Care" [2] is aimed at supporting users in engaging in advance care planning (ACP). ACP is a communication process that enables persons to think about their goals and preferences for future treatment and care, to discuss these with their relatives or health care professionals, and to record these if appropriate [3]. The web-based ACP program guides users through 3 steps of ACP—exploration, discussion, and recording of preferences for future treatment and care (Textbox 1). A before and after study showed that the web-based ACP program increased ACP engagement among persons with a chronic disease and was perceived as usable, attractive, and comprehensible [4]. The program was embedded as a decision aid in the Dutch platform "Thuisarts" [5] in April 2020 (English version "GPinfo website" is in development). This platform is owned and hosted by the Dutch College of General Practitioners and provides evidence-based health-related information to the public.

Textbox 1. Main characteristics of the web-based advance care planning program "Explore Your Preferences for Treatment and Care" [2,4].

Content

- Information about advance care planning (ACP).
- Thinking about values and quality of life.
- Communication about preferences with relatives and health care professionals.
- Appointing a health care representative.
- Recording of preferences in an advance directive.
- Reviewing the advance directive.
- References to information about specific diseases, patient organizations, and peer support opportunities.
- The content was based on a scoping review that explored the content, feasibility, and effectiveness of web-based ACP programs [6]; an interview study that identified information needs for web-based ACP of patients with chronic diseases and their relatives [7]; and meetings with a stakeholder group containing relevant stakeholders for the web-based ACP program including patients, relatives, and patient organizations [4].

Structure

- Interactive program; users can watch videos and click on additional information, users are asked questions regarding ACP and can save a document containing their responses.
- Stepwise approach to guide users through the ACP process.
- Embedment in information platform (Thuisarts website [English version: GPinfo website]) which is hosted and owned by the Dutch College of General Practitioners, and provides evidence-based health information.
- Accessible for free.
- Hyperlinks to external websites.
- Text-to-speech option.

Development

- Developed by researchers (DvdS, IJK, JACR, and AvdH) with expertise in shared decision-making, care at the end of life, and eHealth, in collaboration with stakeholder group including 1 patient, 2 relatives, representatives of the Dutch College of General Practitioners (Nederlands Huisartsen Genootschap), the Dutch Association for Kidney Patients (Nierpatiënten Vereniging Nederland), the Dutch Patient Association (Nederlandse Patiëntenvereniging), Agora (organization to promote the palliative approach), 1 expert in health communication of the Nivel (Netherlands institute for health services research), 1 expert in eHealth of the University of Twente (LvG-P), and 1 representative of Vital Innovators, an organization that conducts Social Return of Investment analyses.
- The development was funded by the Netherlands Health Organisation for Health Research and Development.

Although many eHealth tools are developed, when they are implemented (ie, made available to end users), their sustainable implementation often fails [8]. To identify issues that may hamper the implementation of eHealth tools early, the NASSS (nonadoption, abandonment, scale-up, spread, and sustainability) framework has been developed by Prof T Greenhalgh and her team at Oxford University. The framework is aimed to encourage timely reflecting eHealth applications in health care

and to systematically explore the chances of successful implementation of these eHealth applications by identifying complexities and reducing them [8]. NASSS stands for "nonadoption, abandonment, scale-up, spread, and sustainability over time," which addresses the 5 possible reasons for eHealth implementation to fail [8]. The NASSS framework enables a systematic approach to explore complexities of eHealth tools regarding their implementation; the more complex, the more risk of uptake failure [8]. NASSS focuses at 7 key domains; condition, technology, value proposition, adopters, organization, external context, and embedding and adaptation over time (Figure 1) [8]. A domain can be classified as "simple" when it is straightforward, predictable, and only contains a few components (as in making a sandwich), "complicated" when it contains multiple interacting components (as in building a rocket), and "complex" when it is dynamic, unpredictable, and not easily disaggregated into constituent components (as in raising a child) [8,9]. The NASSS framework postulates that technologies with most domains classified as "simple" are more likely to be successfully implemented than technologies where most domains are classified as "complex" or "complicated." Complexities in different domains can be interdependent, for example, when organizations have difficulty to adopt an eHealth technology, this may complicate adoption of the eHealth tool by staff as well [10,11]. We used the NASSS framework to identify complexities that may hamper sustainable implementation of the web-based ACP program.

Methods

Data Analysis

We evaluated the complexity of the web-based ACP program "Explore Your Preferences for Treatment and Care" [2] using the NASSS framework, following the approach of Abimbola et al [11] who also conducted an ex post (retrospective) thematic analysis.

First, we developed a multimodal dataset consisting of different existing, relevant data sources (Table 1). The dataset includes peer-reviewed and published studies describing the development and evaluation of the program [4,6,7], notes of stakeholder group meetings, and a social return on investment analysis in which the social costs (input) and benefits for stakeholders (outcomes) of the program were mapped.

Next, 2 researchers (DvdS an MAS) developed a data extraction form based on the nonadoption, abandonment, scale-up, spread, and sustainability complexity assessment tool (NASSS-CAT; IRIHS group); the NASSS CAT-LONG interview guide [13]. They used this form to extract relevant pieces of text from the data sources per NASSS domain, that is, (1) condition, (2) technology, (3) value proposition, (4) adopters, (5; previously 6) external context, (6; previously 7) embedding and adaptation over time. We considered the original domain 5, "organization," not applicable because the web-based ACP program is not implemented in a specific health care organization and the hosting organization, the Dutch College of General Practitioners, did not have to change their routines to embed the program. Next, DvdS and MAS together with the wider research group conducted an initial thematic analysis of the extracted information to identify whether sufficient information per domain was available. They conducted 3 additional semistructured interviews to complete the dataset (1) with a representative of the Dutch college of general practitioners (the program host), (2) a general practitioner, and (3) a representative of the organization that funded the development of the web-based ACP program. The interview questions were based on the NASSS CAT-LONG interview guide [13]. Interviewees provided written informed consent for participating in an online interview in which questions were asked about attitudes toward the web-based ACP program related to the domains of the NASSS framework. Interviews were audio-recorded and transcribed verbatim.

Subsequently, DvdS and MAS together with the wider research group conducted a thematic analysis of the final dataset, using the NASSS framework as a lens, leading to a thematic description of complexities per domain. We used relevant ACP literature to further underpin the findings. The conclusion whether a domain is simple, complicated, or complex was based on discussion and eventually consensus among the members of the research group, where we weighed the potential impact and relevance of the different complexities.

Complexities in each of the 6 domains were classified as "simple," "complicated," or "complex." Per domain, all relevant aspects were taken into consideration. An overall classification as "simple" does not require a total absence of room for improvement for a domain; however, most of its elements should be considered as simple. Based on the multimodal dataset and the classification in Multimedia Appendix 1 [8,9], DvdS and MAS prepared a classification per domain, which was discussed during meetings with all researchers (MAS, DvdS, JACR, IJK, and AvdH), until consensus was reached.

Table 1. Overview of the multimodal dataset used to analyze complexities of the web-based advance care planning program "Explore Your Preferences for Treatment and Care."

Sources of information	NASSS[a] framework domains					
	Condition	Technology	Value proposition	Adopters	External context	Embedding and adaptation over time
Results and data from studies:						
Scoping review [6]: • Aim: to determine the feasibility and effectiveness of 11 web-based ACP[b] programs in 27 studies.			✓[c]		✓	
Interview study [7]: • Aim: identifying information needs for web-based ACP. • Participants: 9 patients with a chronic disease and 7 relatives.			✓	✓		
Pilot study [4]: • Aim: assessing the usability and feasibility of the web-based ACP program. • Participants: 3 health care professionals (2 general practitioners and 1 vascular surgeon) and 6 patients with a chronic disease.		✓	✓	✓		
Evaluation study [4]: • Aim: evaluation of ACP engagement (before using the web-based program vs 2 months after completion), usability, and users' satisfaction (including comprehensibility). • Participants: 147 patients with a chronic disease.		✓	✓	✓		
Other available resources:						
Notes of stakeholder group meetings: • Including researchers, patient organizations, patients, and relatives. • Decisions were made concerning the program (eg, definition of target group and content of the program).	✓			✓	✓	✓
SROI[d] analysis: • The social costs and benefits for stakeholders, and mapped investments (input) and revenues (outcomes) of the program. • The SROI methodology followed 9 steps that led to the complete cost-benefit model and the final calculated SROI ratio. • Interviews were conducted with health care organizations, stakeholder group, patients and relatives, and a health insurance company.			✓	✓		✓
Content of the web-based program: • Content, structure, layout, or assembly. • Page with additional information (information about target group and purpose of ACP).	✓	✓				
Platform of the web-based program ("Thuisarts"): • Requirements of the program, consultations with the Thuisarts website. • Guidelines of the Thuisarts website (eg, not saving personal data and maintenance web-based program).	✓	✓		✓	✓	✓

[d]SROI: social return on investment.

Ethical Considerations

This study was approved by the Medical Research Ethics Committee of the Erasmus MC, University Medical Center Rotterdam on October 21, 2019 (MEC-2019-0590), confirming that the rules laid down in the Medical Research Involving Human Subjects Act do not apply to the interviews as conducted in this study. The study conforms with the International Committee of Medical Journal Editors' recommendations for the conduct, reporting, editing, and publication and for the protection of research participants. The interview participants were provided with information about the aim and content of the interview. They provided written informed consent. Interview participants did not receive compensation. The authors confirm that all patient or personal identifiers have been removed or disguised so the persons described are not identifiable and cannot be identified through the details of the story.

Results

The Condition or Illness

The domain "condition or illness" considers to what extent the condition or illness is well-characterized, well-understood, and predictable and to what extent the condition or illness is influenced by comorbidities or sociocultural factors.

Target Group

The target group of the web-based ACP program is described as follows: "people can engage in ACP when they are healthy, but also when they become older or (chronically) ill, after having an accident or when nearing the end of life" [2]. The target group is hence not strictly demarcated, which is in line with recent recommendations [3,14,15]. During the development of the program, demarcating the target population was a recurring issue with some stakeholders promoting a focus on people with advanced illness and others promoting a broader scope. The target group ambiguity is also visible at the Thuisarts website, where the program is embedded: internal links to the program are included in pages about topics such as end-of-life care and dementia.

Sociocultural Factors Affecting Engagement in ACP

The web-based ACP program is aimed at individuals who are interested in ACP, regardless of their religion or culture. The program contains images and videos of both men (n=5) and women (n=3), persons with various ethnic backgrounds, and a wide range of ages (middle age to older adults) [2]. One video in the program includes a reference to a religious belief.

Nevertheless, the program is currently only available in the Dutch language and was only evaluated among Dutch-speaking persons. Multilingual support is not offered, which limits the accessibility of the program to non–Dutch-speaking individuals. The program fosters autonomy and self-management, and uses an explicit and direct communicative style [2]. This approach may be less appealing to people who consider the role of the family to be central in medical decision-making, and to those who prefer a less direct communication style [16]. This may limit the appeal of the program for those who consider the role of the family to be central in medical decision-making, and to those who prefer a less direct communication style [16].

Classification and Conclusion

The "condition or illness" domain is classified as complex given the rather undemarcated target population of the web-based ACP program and because the program may not address the ACP preferences of all potentially eligible persons.

The Technology

The domain "the technology" encompasses a description of the web-based ACP program and the Thuisarts website, as well as user experiences with the technology.

The Web-Based ACP Program Embedded in Thuisarts Website

The web-based ACP program guides users through the process of ACP in three steps, that are (1) thinking about preferences for future treatment and care, (2) discussing these preferences with relatives and health care professionals, and (3) recording these preferences. Users are asked questions, and the answers to these can be saved in a document and printed. Users of the program are recommended to use this document during a conversation with a relative or a consultation with a health care professional. Users do not need to complete the program at once; they can access it at any preferred moment. The program is freely accessible without the need to register and data of users are not saved. Content maintenance of the program occurs through critical review of the program every 3 years by a stakeholder group of patients, relatives, health care professionals, and patient organizations.

The web-based ACP program is embedded in the Thuisarts website, a web-based platform containing information about health and disease, based on evidence-based guidelines (English version "GPinfo website" is in development). The platform is owned and maintained by the Dutch College of General Practitioners [5]. Approximately two-thirds of the Dutch population are familiar with the platform [17], and it has 6.6 million monthly visitors [18]. The content is written on the B1 level (easily readable and concise), and is offered in standardized formats [19], reading text out loud is enabled, and information is summarized in videos with subtitles. Every year, experts test whether the platform has the recommended level for web-based information (level AA) [20] and identified problems are solved [21].

User Experiences With the Technology

A qualitative pilot study showed that the web-based ACP program was acceptable and feasible for 6 interviewed patients with a chronic disease [4]. In an evaluation study among 147 members of an online research portal (who are expected to have at least some digital skills), including people with levels of low, middle, and high health literacy, the program was perceived as user-friendly (mean score of 70, SD 13, scale 0-100), attractive (mean 3.8, SD 0.7, scale 1-5), and comprehensible (mean 4.2, SD 0.6, scale 1-5) [4]. To support people with limited health- or digital literacy in using the program, people can watch videos and use a text-to-speech option to read the text aloud [4]. Furthermore, a clear and simple structure is used and the number of topics covered is not too large [4]. The texts are written on the B1 level (easily readable and concise) [19].

Classification and Conclusion

The "technology" domain is classified as simple because the web-based ACP program is freestanding and well-maintained, with straightforward, well-understood technology. An evaluation study showed that the program is perceived as user-friendly and comprehensible. However, people with limited health literacy or digital literacy might require help to use the program.

The Value Proposition

The "value proposition" domain concerns whether a new technology is worth developing and for whom it may generate value. It includes demand-side value (value for the users) as well as supply-side value (value for the developers).

Value for Stakeholders

In total, 3 interviewed health care professionals indicated they considered the program as valuable to patients [4] and an evaluation study showed that after use of the web-based ACP program, people contemplated about ACP more often and indicated to feel more ready for ACP [4]. They considered the program to be user-friendly and were satisfied with the program [4]. This is in line with findings from a scoping review, which concluded that participants of web-based ACP programs generally consider these programs as easy to use, not burdensome, and feasible [6]. This review also indicated that web-based ACP programs are effective to improve ACP knowledge, communication about ACP, and documentation of ACP among program users [6].

Regarding the value for health care professionals, the funder of the web-based ACP program project and a general practitioner indicated in the additional interviews to consider the program as helpful to start ACP for health care professionals:

> *Some basic things are in there [in the program] which could be discussed: (…) like what is important to someone? That can help as a guidance in your conversation.* [general practitioner]

Costs

The web-based ACP program was developed in the context of a publicly funded research program and has no commercial purpose. The Dutch College of General Practitioners invests in long-term maintenance of the Thuisarts website and they will maintain the web-based ACP program technically as well.

Cost and Benefit Analysis

The web-based ACP program is freely accessible. The Thuisarts website is not aimed at making a profit. It is financed by the Dutch College of General Practitioners and receives no money from companies seeking financial gain, such as pharmaceutical companies. To better understand the relationship between the total investment (costs) and the expected social effects (benefits) of the web-based ACP program, a so-called social return on investment analysis was conducted [22]. This analysis showed that each investment in terms of money, time, and effort, is expected to generate a social return of approximately 1.7. This means that the program is expected to have a positive value for patients, relatives, health care professionals, and the health care system in terms of money or societal value, such as increased quality of life.

Classification and Conclusion

The "value proposition" domain is classified as simple because the technology is expected to generate a positive value for stakeholders (patients, relatives, health care professionals, and

the health care system) while the benefits of the program are expected to exceed the costs. The Dutch College of General Practitioners invests in long-term maintenance of the Thuisarts website and they will maintain the web-based ACP program technically as well.

The Adopters

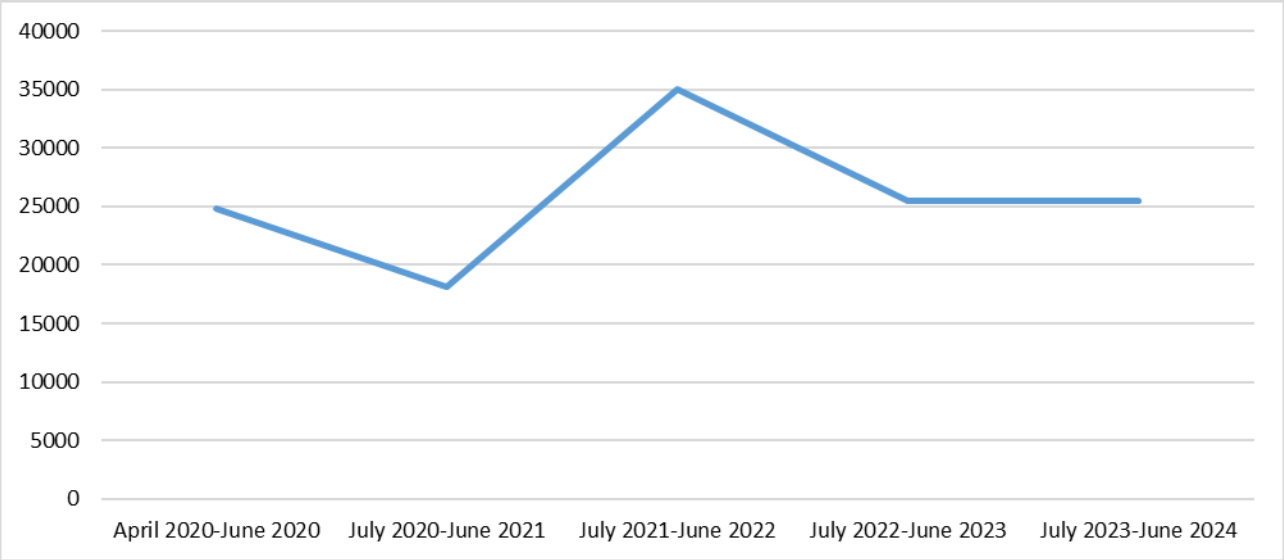
The domain "adopters" focuses on the adoption and continued use of the technology by the groups of people who are intended to actually use the program or to refer potential users to the program, and what they need to use the program or to refer to it. The potential adopters of the web-based ACP program include patients, relatives, health care professionals, and the public in general.

Patients and the Public

Patients with chronic disease and their relatives were asked about their information needs for ACP in a qualitative interview study [7]. They indicated the need for guidance in ACP, information about their disease and care, and information on how to communicate their preferences to relatives and health care professionals [7]. These needs were taken into account in the development of the web-based ACP program. In an evaluation study, users of the web-based ACP program indicated that the program helped them to consider ACP [4]. Users were generally satisfied with the amount of information in the program [4]. A few users mentioned that it was confronting to complete the program because of the difficulty of the topic and a large amount of information. In the first 3 months after its launch (April 1-June 30, 2020) the program was visited 24,849 times. From July 1, 2020, to June 30, 2021, it was visited 18,160 times; from July 1, 2021, to June 30, 2022, it was visited 35,026 times; from July 1, 2022, to June 30, 2023, it was visited 25,423 times; and from July 1, 2023, to June 30, 2024, it was visited 25,510 times. In total, it was visited 128,986 times (Figure 2).

More than 40 medical and patient organizations refer to the web-based ACP program on their websites. However, as described in the domain "condition or illness," not everyone may be interested in engaging in ACP because of a preference to focus on their health and life in the present [23] or valuation of other principles than those central to the web-based ACP program, for example, valuing a central role of the family in medical decision making [16]. While the web-based ACP program is considered useful, it may require substantial commitment and effort of the user in terms of reflecting on their values and preferences for treatment and care.

Figure 2. Visits to the web-based advance care planning program "Explore Your Preferences for Treatment and Care" from its launch (April 1, 2020) to June 30, 2024.



Health Care Professionals

The web-based ACP program recommends participants to involve their health care professionals in the ACP process, for instance, to explain the medical situation, discuss patients' preferences, or file an advance directive. It is known that most people access ACP information through health care professionals [24] and expect that the professional initiates ACP [25]. The Thuisarts website is a frequently used platform among health care professionals; 90% (1751 of 1946) of general practitioners are familiar with it and inform patients about it, and 73% (1421 of 1946) use it for information provision during their consultations [26]. Health care professionals were included in the stakeholder group and provided input during the development of the web-based ACP program. However, opinions about the web-based ACP program of health care professionals have not been extensively evaluated [4]. In total, 3 interviewed health care professionals considered the program to be of value [4]. However, several other studies have described that health care professionals may experience barriers in the initiation of ACP. ACP may be time-consuming, health care professionals report to lack the skills in initiating sensitive ACP conversations [25,27], and they may fear taking away patients' hope [25,27]. Whether the web-based ACP program may support health care professionals to overcome these barriers remains to be studied.

Classification and Conclusion

The "adopters" domain is classified as simple. However, we identified a few complexities. While the web-based ACP

program is potentially useful, it may require substantial commitment and effort of users. Furthermore, it remains to be studied whether the program can support health care professionals to overcome well-known barriers to ACP such as lack of time and fear of taking away patients' hope.

The External Context

The "external context" domain encompasses (1) the policy and political climate, (2) professional organizations and patient organizations, (3) the regulatory context, and (4) the economic context.

Policy and Political Climate

ACP is generally encouraged by organizations of health care professionals in the Netherlands, such as general practitioners, home care organizations, and hospitals. Many initiatives are taken to implement ACP in health care practice such as the development of ACP tools and manuals, websites for the public as well as health care professionals such as Palliaweb website, and ACP modules for electronic patient files [3,28-30]. In addition, the Dutch Ministry of Health, Welfare and Sport has spent €51 million (US $52.6 million) in the period 2014-2020 on research on palliative care including ACP [30] and initiated another research program on ACP in 2022 [31]. Furthermore, the Ministry has organized a public information campaign in 2022 to raise awareness for the importance of timely talking about death and dying [32,33].

Professional Organizations and Patient Organizations

Several patient organizations were involved in the development, evaluation, and implementation of the web-based ACP program. More than 40 organizations, including The Netherlands Patient Federation and the Dutch Association for Kidney Patients, as well as general practitioners and care organizations, referred to the web-based ACP program on their websites and in newsletters.

Regulatory Context

The regulatory context of ACP in general in the Netherlands is supportive regarding ACP. Several professional bodies have developed and provided guidelines for ACP [34], toolkits [35], and manuals for doctors [29,36]. Some of these specifically refer to the web-based ACP program [29,36]. Some materials are specifically developed for patients [37]. However, these ACP materials have different target groups, for instance, health care providers [29,34,36], patients in the palliative phase or at the end of life [3,14,15], or broader populations [3], and therefore it may not always be clear to whom they apply. Regarding the regulatory context of the web-based ACP program, users' privacy is protected in compliance with data security and privacy requirements, by not requiring any log-in procedure and not recording any details of users.

Economic Context

The reimbursement of ACP for health care professionals is not clearly regulated.

Classification and Conclusion

The "external context" domain is classified as simple. Professional bodies are supportive toward the web-based ACP program and ACP in general. We found some complexities, such as different available manuals and tools for ACP containing different recommendations, and the unavailability of a treatment code for health care professionals. However, these external conditions are not likely to complicate the adoption of the web-based ACP program to a large extent.

Embedding and Adaptation Over Time

Overview

The scope of the Thuisarts website is expanding. Information provision was focused on primary care in the past, but currently also includes information on secondary care. The Thuisarts website, including the web-based ACP program, is likely to be maintained in the future, with both technical and content updates. Content maintenance of the program occurs through a critical review of the program every 3 years by a stakeholder group of patients, relatives, health care professionals, and patient organizations. They will review compliance with (evolving) data security regulations, privacy requirements, and policies. If necessary, the program will be adapted. At this time, no changes in data protection regulations or policies are expected in the near future that would affect the program.

Our evaluation study showed that in general, participants had a positive user experience and were satisfied with the web-based ACP program [4]. To further improve this, we are systematically collecting informal feedback on the program and visitor numbers. These will be discussed during each 3-yearly review of the program by the stakeholder group. If necessary, they will make recommendations to adapt the program. To do so, the web-based ACP program will be adapted using an iterative design strategy of ongoing collecting informal feedback and the editorial team of the Thuisarts website adapting the program accordingly. Based on the feedback, user experience and satisfaction are aimed to be enhanced by improving the usability and feasibility of the web-based program.

Classification and Conclusion

We classify the "embedding and adaptation over time" domain as simple, since it is unlikely that the web-based ACP program as embedded in the Thuisarts website or its value are significantly going to change in the next years.

Discussion

Principal Results

To analyze the implementation of the web-based ACP program "Explore Your Preferences for Treatment and Care," the NASSS framework was used to identify complexities within 6 domains. The analysis revealed no or little complexity in the domains "technology," "value proposition," "external context," and "embedding and adaptation over time." The program is evidence-based, freestanding, and well-maintained, with straightforward, well-understood technology. The program is expected to generate a positive value for different stakeholders as well as for the Thuisarts website. The analyses revealed some complexities in the "condition" domain, including the broad and rather undemarcated target population of ACP and the web-based ACP program and sociocultural factors that may

limit users' engagement. In the "adopters" domain, complexity entails that the program requires substantial commitment and effort by users with respect to reflecting on their preferences for future treatment and care. Some people with limited digital literacy may need support to use the program. Furthermore, it is yet unstudied to what extent health care professionals adopt the web-based ACP program. The program is embedded in the general practitioners' platform "Thuisarts," which is frequently used by general practitioners and the general public. The fact that the web-based ACP program is not embedded in a specific health care organization simplified its implementation, since no alignment regarding content or layout was required. On the other hand, embedding the program in the routine practice of a health care organization, could have boosted its use. Finally, we found some complexity in the "external context" domain. While the political and policy climate, regulatory context, professional organizations, and patient organizations are generally supportive regarding ACP, a national guideline for ACP and a treatment code to reimburse ACP could further increase willingness and ability of health care providers to engage in ACP. Overall, the analysis showed that the program has good potential for sustainable implementation, as it is expected to be continuously used in practice [8,38,39], will be updated if necessary, and will be maintained long-term.

Comparison With Previous Work

The results of this study showed that the web-based ACP program "Explore Your Preferences for Treatment and Care" has relatively few complexities regarding the implementation. This may have several reasons. First, the user-centered design of the program included an extensive preparatory phase, including a scoping review to learn from existing web-based ACP programs [6], identification of the needs of patients with chronic disease and their relatives for web-based ACP in an interview study [7], and close collaboration with stakeholders including patients and relatives. Second, during the development of the program, we paid due attention to sustainable implementation in an existing, well-used platform—"Thuisarts." The team of the Thuisarts website has expertise in developing information for the public with different levels of health literacy. It is remarkable that other web-based ACP programs often seem to have not paid due attention to implementation. Three recent reviews about web-based ACP programs [6,40,41] showed that studies have mainly focused on the development of web-based ACP programs and evaluation of their feasibility, usability, acceptability, and effectiveness, but most did not address their implementation. This is in line with reviews about implementing eHealth in general showing that research has mainly focused on the content and evaluation of eHealth tools, but less so took into account the external context and sustainable adoption in health care systems [8,10].

The results of the current study also indicated that health care professionals are an important group of adopters for the web-based ACP program. The web-based ACP program, following existing guidelines, recommends an active role of health care professionals in the ACP process of patients, for instance, to discuss diagnosis, prognosis, and relevant treatment and care options with the patient, and to document the ACP process in the medical file [3,4]. In the literature, several barriers are described that health care professionals may experience in the initiation of ACP, such as lack of time, lack of skills in conducting ACP conversations, and fear of taking away patients' hope [25,27]. In the development of the web-based ACP program, the role of health care professionals was to a limited extent taken into account. First, the program is embedded in the general practitioners' platform "Thuisarts," which is frequently used by general practitioners [26] and the general public [17,18]. Furthermore, health care professionals were included in the stakeholder group and provided input during the development of the web-based ACP program. In the program, the user is encouraged to discuss and share their preferences with their health care professionals at several points [2]. However, the actual use of the web-based ACP program among health care professionals and their views and experiences regarding the program, are unstudied. Given the barriers that health care professionals may experience in the initiation of ACP [25,27], a patient-centered and community approach of ACP is important, in which patients can also take the initiative to engage in ACP themselves. This is central to the program, as the program supports the initiation of ACP, self-management of users, and encourages conversation with health care professionals about values, goals, and preferences.

The results indicated complexities considering the broad target population of ACP in the web-based ACP program. This complexity is a reflection of the evolving concept of ACP in the literature. Initially, ACP was conceptualized to be used for patients in the palliative phase and at the end of life [3,14,15]. More recently, an international consensus study on ACP recommended that individuals can engage in ACP in any stage of life, but that ACP can be more targeted when individuals' health condition worsens or when their age increases [3]. This evolving concept of ACP aligns with the evolving concept of palliative care, whose definition has widened from a sole focus on the end of life to also including chronic illnesses [42] and a shift from in-hospital to community-based care [43]. Reaching the community with high-quality information and guidance about ACP through the Thuisarts website may therefore fit these developments.

Strengths and Limitations

A strength of this study is our systematic approach of evaluating the web-based ACP program using the NASSS framework. It provided insight in its complexities that might hamper its implementation. Furthermore, we had a large dataset including publications about the development and evaluation of the web-based ACP program, notes of stakeholder meetings, and interviews with the program host, a general practitioner, and a funding agency representative. Insight into the complexities may be used to improve future sustainable implementation of the program, and may be used to improve other web-based programs as well.

A limitation is the start of the NASSS evaluation after the tool was developed and embedded in the Thuisarts website, which has limited the opportunity to adapt the program during its development. Some of the authors (DvdS, JACR, AvdH, and IJK) were the developers of the web-based ACP program, and therefore they could provide in-depth insight in the

developmental process. However, although the authors aimed to analyze the implementation of the web-based ACP program objectively, there can be a bias in the evaluation.

Recommendations to Improve Complexities of the Web-Based Advance Care Planning Program

To enhance sustainable implementation, we provide several recommendations to improve the identified complexities of the web-based ACP program.

First, to make the program available in other languages than Dutch. This may further enhance the accessibility of the program to people with different languages. For instance, an English version of the program could be placed on the GPinfo website, which is the English version of the Thuisarts website that is still in development. The web-based ACP program may be translated to other languages as well, to enhance its accessibility to people who are not proficient in Dutch. To improve cultural inclusiveness, future research should explore the needs of people from various cultural backgrounds with regard to ACP and if desired, the program could be culturally adapted or different versions of the program could be developed.

Second, to enhance accessibility of the web-based ACP program to persons with very limited health or digital literacy. The program was developed to assist individuals with limited health or digital literacy, by offering readable texts, text-to-speech options, and videos. However, individuals with very limited health or digital literacy may still experience barriers to use the program. To enhance accessibility of the program for these users, recommendations to complete the program together with a relative could be added to the program. Furthermore, a PDF version of the web-based ACP program could be developed, that could be printed by a relative or health care professional, to make the program also available "offline."

Third, to inform health care professionals about the variance in readiness for ACP among patients. Not everyone may want to engage in ACP [44], for instance, due to different cultural backgrounds and different needs to consider treatment and care preferences. In addition, we recommend to inform and support health care professionals in how to conduct ACP with their patients. The web-based ACP program may help to overcome lack of time, since health care professionals can refer to the program, patients can prepare themselves for an ACP discussion on beforehand, and then the discussion with the health care professional can be scheduled.

Fourth, the concept of ACP as an ongoing process of considering preferences (also including healthy individuals) [3], could be embedded in national guidelines, and be routinely integrated in health care practice to reach a broader target group for ACP. National guidelines and availability of a treatment code may lower barriers in ACP for health care professionals, and may consequently lead to increased engagement with ACP for patients. Websites aimed at the general public could refer to the web-based ACP program, for instance, pages about shared decision-making and pages within the Thuisarts website about chronic diseases. Furthermore, we recommend to conduct public awareness campaigns about ACP (including web-based ACP programs), as these have been found to enhance awareness of ACP [45]. These may also help to enhance accessibility of ACP for people beyond the medical health care setting.

Finally, to ensure adaptation of the program to evolving data protection requirements. During critical review of the program, that will take place every 3 years by a stakeholder group of patients, relatives, health care professionals, and patient organizations, compliance with (evolving) data security regulations, privacy requirements, and policies should be carefully reviewed. If necessary, the program should be adapted. In addition, the strategy of the Thuisarts website, the host of the web-based ACP program, is aimed at adapting the information on the Thuisarts website to the evidence-based guidelines for general practitioners as developed by the Dutch College of General Practitioners. When guidelines change, the information at the Thuisarts website is adapted accordingly by their editorial team. Furthermore, the strategy of the Thuisarts website focuses on collaborating with health care professionals and policy makers, and on including patients' perceptions in the information, to ensure the content is adapted to significant changes in health care landscapes or policies.

Since the domains of the NASSS framework may be interdependent, reducing complexity in a particular domain may consequently also reduce the complexity in other domains. For instance, in case of national guidelines on ACP, health care professionals may be more willing to initiate ACP with their patients and patients may be more ready to initiate ACP.

Recommendations for Future Research

The following recommendations, based on the results and conclusions of the current study, can aid future implementation of comparable web-based ACP programs.

In order to improve the sustainable implementation of eHealth tools, in particular web-based ACP programs, first, we recommend to systematically and throughout the process (from idea to implementation) assess their complexities, with careful attention for all potential adopters, their external context, and their embedment and adaptation over time. The NASSS framework is suitable to conduct such evaluation, as well as other models that can be used for implementation or sustainability evaluation, such as the Normalization Process Theory (a framework to understand how interventions become embedded or "normalized" in health care settings) [46] and the Centre for eHealth Research Roadmap (CeHRes) [47,48]. These frameworks consider similar domains as the NASSS framework, sometimes ordered slightly differently, and can provide guidance for the sustainable development and implementation of eHealth technologies [46-48]. We expect that others who aim to implement similar web-based ACP programs and who apply comparable implementation frameworks, will benefit from the findings of this study and the recommendations. Yet, these should be contextualized for each application (eg, aligned with local policy frameworks and targeted to the target groups central in that program).

Second, we recommend identifying all relevant target groups of the eHealth tools, and explore their needs and preferences to ensure the tool meets their needs. For the web-based ACP program in particular, we recommend exploring health care

professionals' perspectives as well as their actual use and awareness of the program.

Third, we recommend assessing as well as improving the attractiveness of eHealth tools to potential users, including a culturally diverse population and to groups with low digital literacy.

Fourth, we recommend that research includes a long-term perspective regarding the implementation of eHealth tools. This may include evaluating the long-term effects as well as the identification of new scientific evidence that necessitates an update of the content of eHealth tools.

Conclusions

Relatively few complexities were identified considering the implementation of the web-based ACP program "Explore Your Preferences for Treatment and Care." The program is evidence-based, freestanding, and well-maintained, with straightforward, well-understood technology. The program is expected to generate a positive value for different stakeholders. Complexities include the broad target population of the program and sociocultural factors. People with limited digital literacy may need support to use the program. Its uptake might be improved by increasing awareness of ACP and the program among a wider population of potential users and among health care professionals. Addressing these issues may guide future use and sustainability of the program.

Acknowledgments

The authors would like to thank the interviewees for participating in this study. The authors would also like to thank the developers of the NASSS framework Prof Dr Trish Greenhalgh and Dr Chrysanthi Papoutsi for their valuable insights regarding the NASSS framework and their permission to reproduce the original NASSS Figure 1 and Multimedia Appendix 1.

This work was supported by the Netherlands Organisation for Health Research and Development (grant 555003026). The funding source had no involvement in the study design, collection, analysis, and interpretation of data, in the writing of the report, and in the decision to submit the paper for publication. The authors declare that no generative artificial intelligence was used in any portion of the manuscript writing.

Data Availability

Research data will be available for verification for at least 15 years. All data will be retained and stored at the central network server of the Erasmus MC, University Medical Center Rotterdam, and can be accessed by those specifically granted access.

Authors' Contributions

All authors contributed to the concept or design of the work or acquisition, analysis, or interpretation of data; drafted the paper or revised it critically for important intellectual content; approved the version to be published; and have participated sufficiently in the work to take public responsibility for appropriate portions of the content.

Conflicts of Interest

None declared.

Abstract

Background: The aging population and the accompanying rise in chronic diseases have intensified the need to study the adoption of telehealth services. However, the success of telehealth services depends not only on their ease and usefulness but also on addressing broader concerns. Despite being a substantial user group in traditional health services, older adults may encounter barriers to adopting telehealth services. Increasing the adoption of telehealth among the older adult population is crucial for enhancing their access to care and managing the challenges of aging effectively.

Objective: We aimed to explore factors influencing the adoption of telehealth services among older adults in Malaysia, going beyond the conventional framework by incorporating transition cost and subjective well-being as additional constructs.

Methods: A cross-sectional survey was conducted among 119 adults aged ≥60 years in Malaysia, using 39 survey items adapted from existing studies. Data analysis was performed using partial least squares structural equation modeling, with both the measurement model and structural model being evaluated. To determine the predictive relevance of the model, PLSpredict was applied. In addition, importance-performance map analysis was conducted to further expand on the structural model results by assessing the performance of each variable.

Results: Of the 119 participants, 52 (43.7%) were women and 67 (56.3%) were men. The study found that subjective well-being (β=0.448; *P*<.001) was the most significant factor, followed by attitude (β=0.242; *P*<.001), transition cost (β=−0.163; *P*<.001), and perceived usefulness (β=0.100, *P*=.02) in influencing telehealth service intention. Furthermore, perceived ease of use (β=0.271; *P*<.001), availability (β=0.323; *P*<.001), subjective well-being (β=0.261; *P*<.001), and trust (β=0.156, *P*=.004) positively influenced perceived usefulness, while inertia (β=0.024, *P*=.22) did not. In addition, availability (β=0.420; *P*<.001) and subjective well-being (β=0.260; *P*<.001) were positively related to perceived ease of use, with inertia (β=−0.246; *P*<.001) having a negative impact. The importance-performance map analysis results showed that subjective well-being (importance=0.532) was the most crucial factor for older adult users, while availability (importance=70.735) had the highest performance in telehealth services.

Conclusions: This research underscores the importance of catering to the subjective well-being of older adults and optimizing the availability of telehealth services to encourage adoption, ultimately advancing health care accessibility and quality for this vulnerable demographic.

Introduction

Background

Telehealth refers to the delivery of long-distance clinical health care services by health care professionals using electronic information and telecommunications technologies. Due to the growth of the internet and communication infrastructure, telehealth has gradually developed into a practical and secure way for patients to obtain reliable information and medical consultation [1]. Using telehealth has several advantages, such as eliminating the need for direct patient–health care provider interaction during regular treatment. Telehealth can also provide remote care, which can reduce the need for medical center resources and increase the accessibility of care.

Previous telehealth studies have developed various concepts to address how telehealth could fulfill the needs of older adults, such as in the context of chronic disease management, enhancing independent living and improving their overall well-being [2]. Telehealth can be useful for older adults with chronic diseases to monitor their conditions at home. For instance, with the use of telehealth, older adult patients can prevent unnecessary hospitalization and still ensure they receive emergency treatment in a cost-efficient manner [3,4]. In addition, Chou et al [5] found that telehealth can improve the well-being of older adults by enhancing their quality of life. Furthermore, telehealth can promote independent living at home among older adults [6].

Older adults could benefit from telehealth as they are the fragile groups who may need this service sooner or later. Nevertheless, they are also the group most concerned about technology. The literature provides evidence that older adults can receive several advantages with the use of telehealth services, such as health monitoring and care, disease prevention, improved quality of life, and independent living. Despite all the advantages, the adoption of telehealth technology may be challenging for older adults because they are slower and more resistant to adopting new technology as they tend to be more traditional, cautious, risk-averse, and suspicious toward innovations [7]. There is a lack of knowledge about what factors individuals will consider when accepting telehealth [8]. The market response indicates that acceptance of technology by older adults is a complex problem that is impacted by a variety of factors rather than just the technology's performance or cost [9].

In the context of Malaysia, telehealth is becoming increasingly important in the health care system, especially with the older adult population expected to exceed 15% by 2030 [10]. This demographic shift will place added pressure on the health care system, particularly due to a rise in chronic diseases [11]. Malaysia's health care system offers accessible services but faces a workforce shortage to meet growing demands. With 2.4 physicians per 1000 people—fewer than those in Singapore, Japan, and Australia—Malaysia faces an aging population and staffing shortages leading to overcrowded public hospitals and strained health care capacity [11]. This has drastically burdened the health care system in Malaysia.

In response, telehealth offers a vital solution to address the growing imbalance between health care supply and demand as health care needs continue to rise [12]. The Malaysian government has been actively exploring technological solutions and launching telehealth initiatives to address the rising health care needs of its aging population. For instance, Malaysia's Ministry of Health initiated a teleconsultation at public hospitals to improve health care access and reduce congestion. Despite these efforts and the recent surge in telehealth-related studies, there remains a scarcity of research to investigate telehealth adoption in emerging economies, especially from the older adults' perspective [11,13]. Investigating telehealth adoption by older adults across different countries is essential, as varying levels of technological development and cultural contexts substantially influence their attitudes and behaviors [13,14].

Previous studies on technology adoption among older adults span various cultural contexts, revealing distinct factors influencing their behavior. In Canada, a study by Ahmed et al [15] found that >half of older adults adopted new technology for online social interactions. Despite having the knowledge to stay connected, they faced challenges like limited access and motivation. In a cross-cultural survey by Elimelech et al [16], older adults in Israel, France, and Spain exhibited different perceptions of technology use, emphasizing the need for culturally tailored adaptations. In Australia, Catapan et al [17] reported that patients had a high level of confidence and trust in the use of telehealth. Meanwhile, in China, Lin et al [18] showed that telehealth's ease of use and usefulness played a substantial role in affecting its adoption. In a developed country such as Singapore, Zhang et al [19] found that telehealth effectively supports the health-seeking behavior of older adults, challenging the belief that they resist technology and lack proficiency. Similarly, Haimi and Sergienko [20] found that telehealth uses among older adults in Israel remained elevated after the COVID-19 pandemic, indicating their ability to effectively learn and use digital health services.

However, in Malaysia, older adults may have different perceptions of telehealth. According to Ting et al [21], many older adults still prefer face-to-face interactions due to a cultural preference for personal consultations. Reservations about the impersonal nature of telehealth remain a substantial obstacle. However, the behavior of older adults toward telehealth in emerging economies, such as Malaysia, remains underexplored. There is a need for research focused on telehealth adoption within the Malaysian context to gain better grasp of this context.

Theory

Researchers have introduced various theoretical models to explain consumer behavior in the context of technology adoption. Well-established models for predicting technology acceptance among consumers include the theory of planned behavior by Ajzen [22], the technology acceptance model (TAM) by Davis et al [23], TAM2 by Venkatesh and Davis [24], the unified theory of acceptance and use of technology by Venkatesh et al [25], and TAM3 by Venkatesh and Bala [26], among others.

A growing body of research highlights the reliability and effectiveness of the TAM in explaining technology adoption. TAM, introduced by Davis et al [23], uses the concepts of perceived usefulness and perceived ease of use to elucidate how

technological factors influence a consumer's intent to adopt a specific technology. For the adoption of health-related technologies, the TAM and the unified theory of acceptance and use of technology have emerged as 2 prominent models, as demonstrated in studies by Harst et al [27], Heinsch et al [28], Rouidi et al [29], and Lin et al [18]. In the context of the aging population, a recent systematic literature review by Yap et al [30] confirmed that the TAM is the most widely used theory for explaining technology adoption among older adults.

Despite the widespread use of the TAM in the literature, previous studies argued that solely using the fundamental TAM to identify the consumer's technology adoption is insufficient [31,32]. Similarly, Attié and Meyer-Waarden [33] criticized that functional and utilitarian benefits, such as perceived ease of use, are insufficient to explain technology acceptance. Therefore, it can be found that previous studies have frequently extended the original TAM with additional variables or other theories to better reflect the technology's acceptance. For instance, Zhou et al [34] extended the original TAM by incorporating perceptions of medical service quality and information quality into the model for predicting telehealth acceptance among older adults. Telehealth acceptance, in turn, is influenced by older adults' perceptions of telehealth and their current behavioral intentions toward telehealth services. In addition, Rho et al [8] extended the TAM with perceived incentives, self-efficacy, and accessibility of patients' medical records, while Klingberg et al [35] included image, self-efficacy, voluntariness, compatibility, and anxiety in the TAM fundamental framework to enhance the explanatory power of the TAM. Moreover, integration of theories and perspectives has been performed as well, such as in the study by Tsai et al [36] that integrated the TAM with the status quo bias and technology anxiety concept to explain the telehealth intention. Therefore, it is suggested that there is a need for research to expand the TAM by including additional variables to provide a more comprehensive explanation and understanding regarding the telehealth intention of older adults.

Objectives

The objectives of this study are as follows:

- To investigate the coexistence and possible effects of TAM constructs, transition cost, and subjective well-being on telehealth service adoption among older adults
- To examine how inertia, availability, subjective well-being, and trust relate to the TAM's key antecedents

Methods

Research Model and Hypothesis Development

Overview

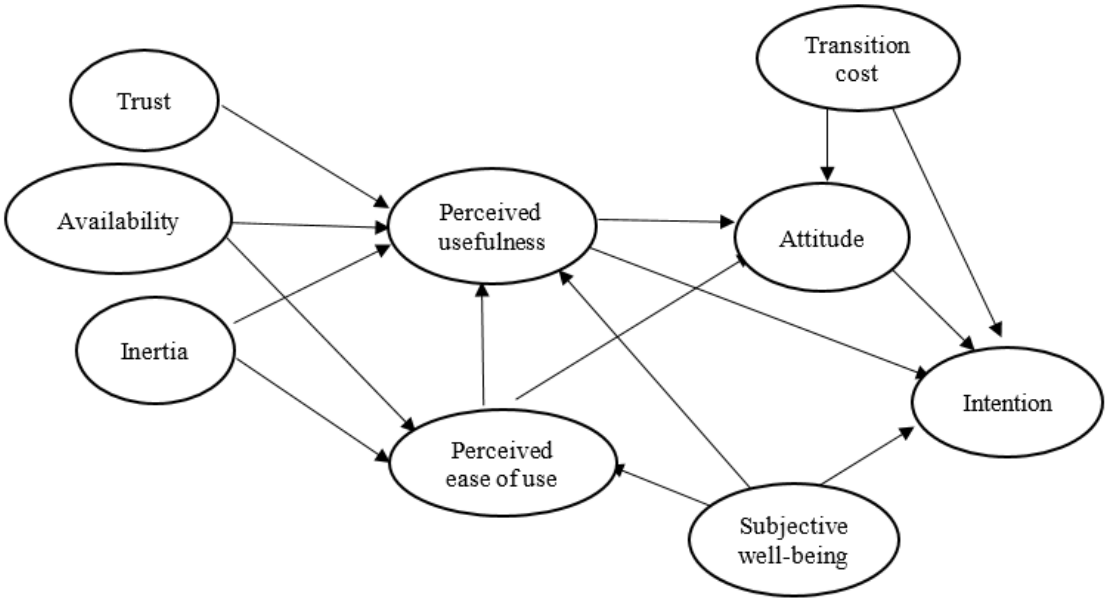
Telehealth is an effective and advanced alternative method for delivering health care services. In the context of telehealth adoption, the fundamental TAM might be insufficient to explain the telehealth adoption among older adults. In particular, the older adult population might often hold negative opinions about technology's inaccuracies that would influence their intention to use it [37]. Considering the evolving landscape of telehealth adoption among older adults in Malaysia and the limited existing literature, this study contributes to the expansion of the TAM. It does so by introducing and exploring a set of key factors aimed at comprehending the older adult population's willingness to embrace telehealth. In addition to attitude and perceived usefulness, this study proposes 2 additional constructs: transition cost and subjective well-being, to evaluate older adults' intention to use telehealth.

First, subjective well-being is included to address critiques of the traditional TAM. Recent studies [11,32,33] argue that the TAM's focus solely on utilitarian benefits is insufficient to fully explain consumer technology adoption. On the basis of transformative consumer studies and the uses and gratification theory [38], it is evident that beyond utilitarian benefits like usefulness and ease of use, consumers also seek affective elements, such as well-being when adopting a new technology [33]. The literature suggests enhancing the TAM by incorporating affective elements like subjective well-being to more accurately predict technology adoption [11]. Nevertheless, subjective well-being has received minimal attention in telehealth adoption studies, particularly from the perspective of the older adult population. Therefore, research proposes that subjective well-being be considered as one of the predictors of older adults' intention to use telehealth. If older adults perceive that telehealth can enhance their well-being, they are more likely to adopt it, as people naturally seek experiences that improve their overall quality of life [39,40].

The inclusion of transition cost as an extension to the TAM is grounded in the status quo bias theory, which posits that individuals tend to prefer maintaining their current routines over adopting change [41]. This is especially relevant for older adults, who often find transitions, such as shifting to telehealth, burdensome due to the perceived effort, time, and disruption of familiar health care practices like face-to-face consultations. Many older adults grew up in a time when technological innovations were not widespread, leading them to develop long-standing routines that provide comfort and predictability [42]. As a result, this study proposes that transition costs are particularly impactful for this group, as they are more likely to resist switching to telehealth in favor of maintaining their familiar health care practices.

Furthermore, the research incorporates availability, trust, inertia, and subjective well-being as factors influencing the TAM constructs. Subsequent sections of this study will provide a detailed analysis of the significance of these constructs within the unique context of this research. Figure 1 shows the research model of this study. The proposed hypotheses based on the developed research model are discussed in subsequent sections.

Figure 1. Research model.



Attitude

Attitude is an evaluation of effect, which refers to a person's positive or negative feelings regarding performing the respective behavior [43]. The impact of attitude on behavioral intention is a significant relationship in the theory of reasoned action, the theory of planned behavior, and the TAM. The connection between one's attitude and their intention signifies that individuals are more inclined to embrace technology if they hold a favorable perception of it, as noted by Davis et al [23]. The concept of attitude has played an important role in numerous studies seeking to gain deeper insights into consumers' willingness to adopt health care technologies. Previous research has consistently confirmed that a positive attitude toward health care–related technologies among consumers has a substantial impact on their intent to use such technologies, as evidenced by studies conducted by Park et al [44], Papa et al [45], Rajak and Shaw [46], and Ahn and Park [47].

Furthermore, Tsai et al [36] unveiled that the older adults' attitudes exert a positive influence on their intention to adopt telehealth. In addition, prior research has shown that attitude can serve as a mediator between beliefs and behavioral intent, as demonstrated by the work of Yang and Yoo [48]. Consequently, this study proposed the following hypothesis:

- Hypothesis 1: there is a positive association between attitude and the intention to adopt telehealth.

Perceived Ease of Use

Perceived ease of use is defined as the degree to which an older adult perceives that using telehealth technology would be free of effort. Perceived ease of use is one of the key constructs in the TAM. According to the TAM, perceived ease of use is related to attitudes and perceived usefulness of new technologies, which also influences intention [24]. Previous research has found that perceived ease of use influences consumers' attitudes and perceived usefulness toward new technologies [31,36,46,47]. For instance, Lazaro et al [49] confirmed that perceived ease of use positively affects the older adults' perceived usefulness and their attitude toward wearable health care technology. Hence, we proposed the following hypothesis:

- Hypothesis 2a: there is a positive association between perceived ease of use and perceived usefulness.
- Hypothesis 2b: there is a positive association between perceived ease of use and attitude.

Perceived Usefulness

Perceived usefulness is defined as the degree to which an individual feels that using a certain technology will improve their job performance [23]. Researchers have supported perceived usefulness as a crucial factor that predicts various types of technology adoption among older adults, such as the internet [50], social networking sites [51], health monitoring wearable technologies [52], telehealth [53], and automation technology [54]. Besides, previous studies revealed that perceived usefulness was highly relevant in predicting telehealth acceptance among the older adult population [34,55]. In addition, perceived usefulness influences consumers' attitudes toward new technologies [36,46,47]. Therefore, the following hypothesis is proposed:

- Hypothesis 3a: there is a positive association between perceived usefulness and attitude.
- Hypothesis 3b: there is a positive association between perceived usefulness and intention to adopt telehealth.

Transition Cost

According to Kim and Kankanhalli [56], transition costs refer to the user's perceived disutility that they incur when switching from the status quo to a new technology. When older adults consider using new technology, such as telehealth, the transition costs involved are essential. Transition costs that are uncertain might become a barrier and negatively influence a person's attitude [57]. In addition, Hsieh [58] revealed that the transition cost that might be incurred when using health-related technology

is one of the key concerns for technology adoption. An individual is likely to continue and remain with an existing system if the transition costs involved, such as effort and time, to learn to use a new technology, are deemed to be high. In the context of telehealth adoption, Tsai et al [36] claimed that transition costs negatively affect older adults' attitudes and hence affect their telehealth adoption. Therefore, if the transition cost to use a new technology is high, older adults will have a negative attitude toward it and not intend to use it. On the basis of the discussions, the following hypothesis is proposed:

- Hypothesis 4a: there is a negative association between transition cost and attitude.
- Hypothesis 4b: there is a negative association between transition cost and intention to adopt telehealth.

Subjective Well-Being

Subjective well-being refers to an individual's perception of an experience positively by using affective reactions and cognitive judgment instead of objective facts [59]. When adopting new technology, people always seek pleasurable experiences that enhance their well-being [39,40]. Previous studies have revealed that well-being influences consumer technology adoption [60]. Al-Jabri and Sohail [61] revealed that technology's characteristics contribute to a person's well-being. Similarly, well-being could act as a determinant that influences technology use [40]. Wu and Lu [62] have highlighted that positive emotions become a motivator for technology adoption when a person uses technology. In addition, findings show that well-being toward technology positively influences an individual's perceived ease of use, usefulness, and intention across all consumer adoption phrases [33,63,64]. Consumers will develop positive emotions toward technology when they perceive that using it will enhance their well-being. Therefore, positive emotions will positively influence the perceived benefits, such as perceived usefulness and ease of using the technology [33].

Therefore, this study proposes that older adults perceive that telehealth will enhance their well-being, which consequently will influence their perceived ease of use, usefulness, and intention to use telehealth. Therefore, we hypothesize the following:

- Hypothesis 5a: there is a positive association between well-being and perceived ease of use.
- Hypothesis 5b: there is a positive association between well-being and perceived usefulness.
- Hypothesis 5c: there is a positive association between well-being and intention to adopt telehealth.

Inertia

Inertia refers to the degree of a person's willingness to continue using traditional physical products despite knowing that better options are available [41]. Even when better alternatives or switching incentives are available, consumers remain attached to and steadfast in their use of existing technologies [65]. Hence, the greater an individual's attachment toward a thing that he or she is familiar with, the less inclined they are to explore new experiences. In addition, Bem [66] and Petty and Cacioppo [67] claimed that people usually depend on their prior behavior and hence fail to recognize a new technology's advantages. In line with this assumption, older adults always seek to maintain their existing internal and external structures when making adaptive decisions, as they would prefer to continue to engage in similar activities or behaviors as they did throughout their previous experiences [68]. The older adult population grew up in an era when technological innovation was not commonly used. As a result of their early experiences, they might have long been accustomed to receiving health care services physically at hospitals or clinics. Older adults might perceive telehealth as not useful and not easy to operate as they prefer to continue to engage in the behavior they are more familiar with to minimize feelings of anxiety. It is hypothesized that inertia will negatively influence the older adults' behavioral perceptions of a new technology and hence create lower inclinations to use new technologies. Individuals who have high inertia tend to reduce the variety of technologies that are available to them and rely on prior behavior to influence their perceptions and intentions [36]. Therefore, the following hypothesis is proposed:

- Hypothesis 6a: there is a negative association between inertia and perceived ease of use.
- Hypothesis 6b: there is a negative association between inertia and perceived usefulness.

Availability

On the basis of the study by Venkatesh [69], availability refers to the extent to which consumers perceive that they can obtain a technological service or product without barriers, along with the presence of organizational support to help them overcome any challenges in using the technology. A person's control belief about the availability of organizational resources and support structures to enable technology use is related to facilitating conditions [26]. Many previous studies have proved the positive impact of facilitating conditions on technology adoption [70,71]. In the telehealth adoption context, the determinant associated with external control might involve the availability of manufacturer's assistance, where the firms provide consumers assistance to overcome the difficulties of using a new technology. Telehealth technologies can make medical resources available to health care professionals, caregivers, and older adults at any time and from any location, allowing a considerable improvement in patient health care. Wu et al [72] revealed that availability positively influences the perceived usefulness of the telehealth care technology. In addition, previous studies also provided support on the impact of availability in the context of telehealth adoption [73,74]. Similarly, a recent study by Tsai et al [36] revealed that availability is an important predictor in determining perceived ease of use and usefulness of telehealth among the older adult population. According to the existing evidence, this study hypothesizes that availability would increase the older adults' perceived ease of use and usefulness of telehealth.

- Hypothesis 7a: there is a positive association between availability and perceived ease of use.
- Hypothesis 7b: there is a positive association between availability and perceived usefulness.

Trust

Trust is evidently a crucial determinant in health care adoption. On the basis of the study by Gefen et al [75], trust refers to a sense of confidence in the trustworthiness and integrity of the other party. When it comes to technological adoption, trust is essential, especially when the technology is relatively new and might involve risks and uncertainties for the older adult population. Despite trust not being included in the original TAM, it has been incorporated into several of the study contexts. Many existing studies demonstrate that trust has a strong positive influence on technology adoption [45,76]. Previous studies also revealed that trust plays an important role in predicting adoption of health-related technologies (eg, telehealth) [76,77].

In the context of this study, telehealth can be a difficult and complex task, especially for older adults, as its use requires a good understanding of devices to communicate effectively with the health care providers [78,79]. Hence, people might lack trust in using telehealth due to the risks incurred, including unclear regulatory authority in place to deal with issues like confidentiality, misconduct, and liability in telehealth. Older adults, who used to obtain services physically, might have trust issues with telehealth's ability to replace in-person consultations and physical health assessments. Particularly in the IT setting, Li et al [80] revealed that trust is crucial, as people must overcome the perceived risk before technology adoption. Previous research has established the importance of trust in determining health-related technology adoption [46]. For instance, Catapan et al [17], Chew et al [81], and Orrange et al [82] showed that trust substantially affects telehealth adoption. Hence, this study hypothesizes that trust would increase older adults' perceived usefulness of telehealth.

- Hypothesis 8: there is a positive association between trust and perceived usefulness.

Research Instrument Development

The measurement scales were adjusted in accordance with existing literature and tailored to suit our research context. The questionnaire was divided into 2 sections. The first part consisted of the 11 constructs used in this study: attitude, availability, transition cost, perceived ease of use, perceived usefulness, inertia, trust, subjective well-being, and intention to adopt. The second part comprised a survey focusing on demographic characteristics, such as gender and ethnicity. An overview of the instrument is provided in Multimedia Appendix 1 [32,36,83,84].

The scales for attitude, availability, transition cost, perceived ease of use, perceived usefulness, and inertia were taken from the study of Tsai et al [36] and Zhang and Zaman [83]. The measures for subjective well-being were based on the work of Yap et al [32]. Trust and intention were measured according to the work of Wu et al [84]. In total, 39 items were assessed using a 5-point Likert scale, which ranged from *completely disagree* (score=1) to *completely agree* (score=5).

To ensure the questionnaire's reliability, a pilot survey was carried out involving 10 older adults. This pretest, which involved contacting 10 older adults before conducting the web-based survey, was conducted to validate the instrument. On the basis of the feedback received, minor adjustments were made to the questionnaire to improve its effectiveness.

Research Sample and Data Collection Procedure

This study focused on the factors influencing the intention to adopt telehealth among adults aged ≥60 years in Malaysia. This demographic was chosen as research participants due to their increased susceptibility to chronic diseases, as outlined by Tsai et al [36]. Chronic diseases can affect individuals of all ages, but the risk escalates as people advance in age, justifying the selection of this population for our research.

In our data collection process, we used a survey approach to investigate the intent of older adults to adopt telehealth services. Recognizing the challenges in directly reaching this demographic, we engaged students as intermediaries to connect with their family members who were older. This method combines elements of convenience and snowball sampling, as students were encouraged to distribute surveys within their social networks, primarily targeting their older family members. We encouraged student intermediaries to recruit participants from diverse geographic regions and socioeconomic backgrounds to enhance sample diversity where possible.

The rationale behind using student intermediaries was 2-fold: first, it provided a practical and effective means of reaching older adult participants, a group that may not be as digitally connected or comfortable with technology. The student intermediaries, who were trained to administer the survey, acted as trusted conduits, facilitating communication and engagement with older adult participants in a familiar, trustworthy, and less intimidating environment. This helped to overcome potential barriers related to accessibility and comprehension of the survey, ensuring that the older adult participants felt comfortable and supported throughout the process. Hence, it was essential for the student intermediaries to have a thorough understanding of both the study's purpose and the questionnaire to effectively guide their older family members. To ensure this, students underwent a comprehensive briefing before the survey, equipping them with a solid grasp of the questionnaire and its objectives.

Data Analysis

This study conducted data analysis using partial least squares structural equation modeling (PLS-SEM). We used SmartPLS 3.2.8 [85] for PLS-SEM, as it is well-suited for analyzing measurement and structural models without the need for normality assumptions. This is particularly useful because survey research data are often not normally distributed [86]. Furthermore, PLS-SEM offers a higher explanatory power compared to covariance-based structural equation modeling.

Ethical Considerations

This study received formal approval from the Research Ethics Committee of Multimedia University (EA2882021). Informed written consent was obtained from all survey respondents before participation. Respondents were required to read the ethical statement at the top of the survey form and proceed only if they agreed to participate. All collected data are treated with the utmost confidentiality, ensuring anonymity and used solely for

research purposes. Additionally, consent to publish was obtained from all participants.

Results

Respondent Characteristics

The survey was conducted from March 1, 2022, to August 31, 2022, resulting in 125 received samples, of which 119 were considered valid. While this approach offers advantages for reaching a challenging-to-access population, researchers should remain vigilant about potential biases arising from the familial and social connections of the student intermediaries. In the sample, 52 (43.7%) of the 119 respondents were women, and 67 (56.3%) were men. Additional demographic details are provided in Multimedia Appendix 2.

Reliability and Validity Tests

The evaluation of the measurement model involved assessing reliability and validity. In Table 1, all variables exhibited factor loadings >0.7 [87], and Cronbach α exceeded 0.7, signifying a high level of reliability. Both the composite reliability and average variance extracted surpassed 0.7 and 0.5, respectively, indicating strong convergent validity [88]. In the second step of the analysis, we evaluated discriminant validity using the heterotrait-monotrait (HTMT) ratio criterion, as suggested by Henseler et al [89] and Franke and Sarstedt [90]. As indicated in Table 2, the results of the HTMT criterion demonstrate that all HTMT values fall below the threshold of 0.85 for the more stringent criterion. This indicated that the respondents recognized the distinctiveness of all the constructs. The combination of these 2 validity tests affirms that the measurement items exhibited both validity and reliability.

Results of the Structural Model

Following the guidance of Hair et al [91], we reported the path coefficients, SEs, 1-tailed *t* test values, and *P* values using a bootstrapping procedure with 5000 resamples [92]. This large resample size ensures result stability, according to Hair et al [91] and Hair and Alamer [93]. In addition, Hahn and Ang [94] emphasized that *P* values alone were insufficient for hypothesis significance and recommended combining *P* values, effect sizes, and bias-corrected interval for a more comprehensive evaluation. Table 3 presents the evaluation of the hypotheses. Moreover, the results of bias-corrected interval, effect sizes, and variance inflation factor are presented in Multimedia Appendix 3.

Table 3. Hypothesis testing direct effects[a].

Hypothesis	Relationship	Standard β	SD	*t* test value	*P* value
Hypothesis 1	Attitude → intention	0.242	0.058	4.168	<.001
Hypothesis 2a	Perceived ease of use → perceived usefulness	0.271	0.048	5.693	<.001
Hypothesis 2b	Perceived ease of use → attitude	0.209	0.056	3.734	<.001
Hypothesis 3a	Perceived usefulness → attitude	0.456	0.054	8.450	<.001
Hypothesis 3b	Perceived usefulness → intention	0.100	0.050	1.997	.02
Hypothesis 4a	Transition cost → attitude	−0.153	0.055	2.779	.003
Hypothesis 4b	Transition cost → intention	−0.163	0.037	4.357	<.001
Hypothesis 5a	Subjective well-being → perceived ease of use	0.260	0.053	4.927	<.001
Hypothesis 5b	Subjective well-being → perceived usefulness	0.261	0.057	4.531	<.001
Hypothesis 5c	Subjective well-being → intention	0.448	0.047	9.582	<.001
Hypothesis 6a	Inertia → perceived ease of use	−0.246	0.041	5.972	<.001
Hypothesis 6b	Inertia → perceived usefulness	0.024	0.034	0.778	.22
Hypothesis 7a	Availability → ease of use	0.420	0.048	8.725	<.001
Hypothesis 7b	Availability → perceived usefulness	0.323	0.047	6.818	<.001
Hypothesis 8	Trust → perceived usefulness	0.156	0.060	2.620	.004

[a]We used 95% CI with a bootstrapping of 5000.

First, we examined the influence of the 4 predictors on intention. Attitude (β=0.242; *P*<.001), perceived usefulness (β=0.100, *P*=.02), transition cost (β=−0.163; *P*<.001), and subjective well-being (β=0.448; *P*<.001) were all associated with intention. This means that hypotheses 1, 3b, 4b, and 5c were supported.

Second, the impact of the 3 predictors on attitude was investigated. Perceived ease of use (β=0.209; *P*<.001), perceived usefulness (β=0.456; *P*<.001), and transition cost (β=−0.153; *P*<.001) were linked to attitude, affirming support for hypotheses 2b, 3a, and 4a.

Third, perceived usefulness was assessed in relation to 5 predictors. Perceived ease of use (β=0.271; *P*<.001), availability (β=0.323; *P*<.001), subjective well-being (β=0.261; *P*<.001), and trust (β=0.156; *P*<.001) exhibited positive associations, while inertia (β=.024, *P*=.22) showed no significant relationship with perceived usefulness. Consequently, hypotheses 2a, 5b, 7b, and 8 were supported, while hypothesis 6b was not.

Finally, we examined the impact of availability (β=.420; *P*<.001) and subjective well-being (β=0.260; *P*<.001) on perceived ease of use, finding that both were positively related, while inertia (β=−0.246; *P*<.001) was negatively related. This supported hypotheses 5a, 6a, and 7a.

Consistent with the results of previous hypothesis testing, the bias-corrected 95% CIs for all hypotheses (except 6a) confirmed that they did not encompass 0, indicating support for these hypotheses (Multimedia Appendix 3). Furthermore, the variances for intention to adopt (R^2=0.650), attitude (R^2=0.502), perceived usefulness (R^2=.654), and perceived ease of use (R^2=0.475) were generally above 33%. This suggests the model possesses a moderate predictive capacity.

To assess the predictive relevance of the model, Shmueli et al [95] suggested the use of PLSpredict, a holdout sample-based method that produces case-level predictions at either the item or construct level. We used PLSpredict with a 10-fold procedure to assess predictive capability. As demonstrated in Table 4, all the errors associated with the PLS model were lower compared to the linear model, indicating the robust predictive power of our model. Therefore, we can confidently assert that our model exhibits strong predictive capacity.

Table 4. PLSpredict results.

Items for the construct intention	PLS[a]	LM[b]	PLS-LM
INT1[c]	0.734	0.735	−0.001
INT2	0.856	0.866	−0.010
INT3	0.767	0.769	−0.002

[a]PLS: partial least squares.

[b]LM: linear model.

[c]INT: intention.

Results of the Importance-Performance Map Analysis

The importance-performance map analysis (IPMA) of older adults' intention to adopt telehealth services aimed to expand upon the results of the structural model by evaluating the performance of each variable. As mentioned by Hair et al [91], areas requiring management attention are those with high importance but poor performance on a specific endogenous latent variable. In our research, we assessed the impact of latent exogenous factors on the endogenous variable (ie, intention to adopt) in terms of their significance and performance. The results of this analysis are presented in Table 5.

Table 5. Importance-performance map analysis.

Constructs	Performance	Importance
Attitude	63.245	0.241
Perceived ease of use	60.779	0.108
Perceived usefulness	64.078	0.210
Transition cost	52.758	0.200
Inertia	69.450	0.021
Availability	70.735	0.113
Trust	64.529	0.033
Subjective well-being	53.330	0.532

The IPMA results showed that the most important factor was subjective well-being (0.532), followed by attitude (0.241), perceived usefulness (0.210), transition cost (0.200), availability (0.113), perceived ease of use (0.108), trust (0.033), and inertia (0.021).

On the basis of performance, availability (70.735) was the highest, followed by inertia (69.45), trust (64.53), perceived useful (64.078), attitude (63.22), ease of use (60.779), subjective well-being (53.33), and transition cost (52.758). Therefore, it is evident that subjective well-being, attitude, transition cost, and perceived usefulness play crucial roles in influencing the intention of older adults to adopt telehealth, as these constructs exhibit relatively higher total effects (importance) compared to other factors in the model. However, the performance of well-being, attitude, transition cost, and usefulness were relatively lower compared to other factors like availability, inertia, and trust.

In summary, to enhance the intention to adopt telehealth among older adults, managerial efforts should be primarily focused on addressing and emphasizing subjective well-being, while continuing to support and maintain positive attitudes and perceived usefulness. On the other hand, perceived ease of use should be given lower priority.

Discussion

Principal Findings

This study aims to enhance the existing TAM for the adoption of telehealth services among older adults in the Malaysian context. Apart from attitude and perceived usefulness, this study proposed 2 additional constructs, namely subjective well-being and transition cost, for assessing the intention of older adults to use telehealth. Furthermore, this study introduced availability, trust, inertia, and subjective well-being as antecedents of TAM constructs. The study found that subjective well-being is the most important factor in telehealth adoption, followed by attitude, transition cost, and perceived usefulness. Perceived ease of use, perceived usefulness, and transition cost substantially affected attitude. Perceived ease of use, availability, subjective well-being, and trust positively influenced perceived usefulness, while inertia did not. In addition, availability and subjective well-being were positively related to perceived ease of use, with inertia having a negative impact. IPMA results showed that subjective well-being was the most crucial factor for older adult users, while availability had the highest performance in telehealth services.

As expected, this study found that attitude positively affects intention, which is in line with the existing health care–related studies, such as those by Park et al [44], Papa et al [45], Rajak and Shaw [46], and Ahn and Park [47]. As per the results, the key TAM construct, perceived ease of use, positively influences older adults' perceived usefulness and attitude toward the telehealth system. These outcomes corroborate the findings of Rajak and Shaw [46] and Ahn and Park [47], which indicate that older adults will have a positive attitude toward telehealth and perceive it to be useful to them if telehealth is easy to use. On the other hand, perceived usefulness also positively influences older adults' attitude and intention toward telehealth. Specifically, perceived usefulness has a significantly larger influence on attitudes regarding adopting telehealth than perceived ease of use (0.456 vs 0.209). The rationale behind these findings may be due to the relevance of using telehealth for managing older adults' health. Hence, the usefulness of telehealth is the priority as compared to its ease of use. In other words, older adults are more likely to use telehealth services if they can provide useful features to them, such as improving their quality of life and offering better health care services.

Consistent with previous findings [36,57,58], these findings show that transition costs are driving forces that have a negative impact on the older adults' attitude and intention to use telehealth. According to the findings, older adults do not intend to use telehealth and will continue using the traditional method of obtaining health care services if they believe the time and effort required to learn telehealth is too high.

Besides, inertia was found to negatively influence the perceived ease of use but had no impact on the perceived usefulness. The significance of inertia's influence on perceived ease of use stems from the fact that ease of use is directly linked to how simple or user-friendly telehealth appears. When older adults experience inertia, they tend to resist adopting telehealth because of the additional effort required to learn and adapt to new technologies. This resistance (inertia) makes new systems seem more complex, thereby reducing the perceived ease of use of telehealth among older adults. However, the significance of inertia on perceived ease of use contradicts the findings of Tsai et al [36], where inertia had no effect on ease of use. This discrepancy may stem from the fact that the majority of respondents in the study by Tsai et al [36] were younger (>40 years) with higher digital literacy, while our study focuses on those aged ≥60 years. In contrast, the insignificant impact of inertia on perceived usefulness in this study is consistent with the findings of Tsai et al [36]. This is because perceived usefulness is more about the functional benefits the user gains from the technology. Hence, even if older adults perceive the system to be hard to use due to inertia, they might still acknowledge that the system provides value or could be beneficial in terms of performance and efficiency. This can explain why inertia does not affect perceived usefulness to the same extent.

Availability showed a positive influence on ease of use and perceived usefulness, which is consistent with existing studies, such as those by Chang et al [74] and Tsai et al [36]. However, these findings partially conflict with the findings of Wu et al [72], which revealed that availability only influences the perceived usefulness and has no impact on the perceived ease of use. This revealed different perspectives between patients and hospital professionals toward the importance of availability in determining telehealth adoption. From the older adult users' perspective, the study's findings revealed that the availability of assistance, such as providing responses to assist them in overcoming obstacles when using telehealth, is very important, which would affect their perceived ease of use and usefulness of telehealth.

This study revealed that well-being positively influences perceived ease of use, perceived usefulness, and intention toward telehealth. These outcomes are expected as people always seek pleasurable experiences that can enhance their well-being when adopting new technology [39,40]. These findings are also consistent with previous results, which showed that an individual's perceived well-being toward technology will positively influence their perceived ease of use, usefulness, and intention [32,33,63,64].

Furthermore, this study also revealed that older adults' trust positively influences the perceived usefulness and attitude of telehealth. This finding is predictable because most older adults prefer to receive services in-person and may have trust issues with telehealth's ability to replace in-person consultations and physical health assessments, so they may perceive high risks and lower trust toward telehealth. The study validates the findings of Rajak and Shaw [46], who revealed the crucial role of trust in the health care technology adoption among older adults.

Conclusions and Implications

Given the rapid growth of the older adult health care industry, improving health care–related services is a promising opportunity. Hence, this study was conducted to investigate the factors influencing the intention of older adults to use telehealth services by extending the TAM model. The model has been stretched to incorporate factors like availability, transition cost, trust, inertia, and well-being. From the literature, it was observed that a considerable number of studies have been conducted on telehealth. However, there is no evidence in the literature of incorporating these factors and further assessing the model in the Malaysian context. In addition, although several papers have adopted the TAM to investigate telehealth adoption, there are limited studies investigating the formation of the TAM key constructs (perceived ease of use and perceived usefulness) in depth from the older adults' perspective. With the introduction of these constructs into the TAM model, this study can contribute to the literature by providing a better understanding of factors affecting older adults' intention to use telehealth in the Malaysian context.

This study has several practical implications. First, the positive impact of attitude toward older adults' intention on telehealth use provides valuable implications to the health care centers and managers. They should create an environment that can ensure older adults have a positive attitude toward telehealth. On the basis of the findings, positive attitude toward telehealth can be enhanced in several ways, for example, when the older adults perceive it to be useful and easy to use. Hence, the telehealth developer and health care personnel should carefully assess telehealth's usefulness in assisting older adults' health care before it is introduced to them.

In addition, telehealth developers should also design an older adult–friendly interface that is easier for them to navigate and understand, as the older adults are not as digitally literate as the younger generation. For example, a case study by Pires et al [96] emphasizes the importance of simplicity and ease of use in successfully implementing the VITASENIOR-MT telehealth system for older adult users. By using television as the primary interface, the telehealth system became more accessible and easier by integrating familiar technology into the homes of older adults. Health professionals provided valuable feedback on design and usability, enhancing the system's effectiveness as they remotely monitored patients. This case exemplifies the best practices in telehealth design, highlighting the significance of user-centered development that prioritizes ease of use for older adults. In addition, health professionals are encouraged to actively engage in the development process to further improve the system's effectiveness. A clear step-by-step video tutorial, easy interactive dialogue, and straightforward click-through procedures for making health care appointments can be introduced. Moreover, the government or relevant authorities can provide older adults with training on how to use telehealth services to improve their skills and confidence in accessing online services.

The results from this study revealed that if the transition cost required when using telehealth is perceived as high, it will cause people to have a negative attitude and intention toward

telehealth. Furthermore, results also indicate that older adults tend to keep using their habitual ways to obtain health care services, which is known as inertia in this study. This inertia negatively affects their perceived ease of use and usefulness of telehealth. The rationale behind these results might be related to the fact that most commonly available smartphone devices, such as tablet computers and smartphones, as well as mobile internet subscription plans, are generally sold at a high price. Therefore, older adult mobile users only seek to access the internet through free Wi-Fi networks due to the high cost of using mobile devices. Given these considerations, it is recommended that telecommunications companies collaborate with government agencies to launch programs that offer special low prices, rebates, or government-funded subsidies for older adults when they purchase a mobile device and sign up for mobile internet packages. For instance, telecommunication companies in Taiwan have effectively held a promotional campaign for older adults to access the internet for free for a certain period [97]. Through a short, free trial, older adults' increasing internet accessibility is an effective way to encourage them to learn and become familiar with mobile apps and to reduce their inertia by providing a greater understanding of the mobile services' value and usefulness, particularly the telehealth services.

In addition to utilitarian-oriented benefits like usefulness and ease of use, which have been frequently discussed in earlier literature, policy makers and managers must also highlight the affective components like well-being [33]. Surprisingly, the result revealed that well-being is the most important factor that affects older adults' intention for telehealth use. Hence, practitioners should pay more attention to developing a sense of well-being enhancement if older adults use telehealth services. For instance, relevant authorities can create an online community of innovative users where the older adults can share their pleasant, positive, and healthy experiences to highlight the well-being provided by telehealth, and hence indirectly generate positive word of mouth that motivates the potential users to use telehealth. On the other hand, findings also revealed that availability positively influences older adults' perceived ease of use and usefulness of telehealth. Therefore, technology developers, manufacturers, or organizations should always be prepared to respond and assist the older adult in overcoming challenges and obstacles when using telehealth services, particularly during the early stages of adoption.

Furthermore, the study's findings also revealed that older adults' trust positively affects the perceived usefulness. Incorporating trust as a key determinant of perceived usefulness is particularly important for older adults adopting telehealth. The literature suggests that trust in telehealth can be fostered through mechanisms, such as confidence in the competence of health care providers [17,81,82] and the reliability of the information provided [98]. In practice, trust can be strengthened by implementing ongoing professional development and telehealth-specific training for health care providers. This can ensure they remain updated on best practices and patient care, thus boosting patient confidence in their competence. In addition, regularly updating health information and cross-referencing it with evidence-based guidelines reinforces the reliability of the information provided on telehealth platforms.

Moreover, government authorities and telehealth platform developers play a critical role in improving trust in using telehealth services. As a result, it is suggested that government agencies implement clear and detailed support policies for telehealth services. For instance, the government should strengthen the laws to ensure that the platform developers ensure the confidentiality of patient data and data security while health care institutions and staff are qualified. The introduction of national policies shows the government's support for telehealth services, which could increase the public's trust toward them [99]. In addition, managers should assist in the development of telehealth platforms by implementing and promoting features and guidelines on patient data confidentiality and privacy protection to establish customer trust. Furthermore, the use of secondary data and security policies should be communicated and advertised by companies to increase trust. In addition, the government should also provide sufficient budget allocation and training for health care professionals to use telehealth services so they can provide better telehealth services for patients and, in turn, increase their trust in telehealth services.

Limitations and Suggestions for Future Research

Like all research endeavors, this study is not immune to limitations. The first constraint becomes evident through the limited number of determinants examined concerning the intention to use telehealth services. We recognize that numerous potential factors remain unexplored, particularly within the realm of customization.

Second, our research adopts a cross-sectional survey design approach. Given the rapid evolution of technology and the increasing familiarity of consumers with telehealth, this approach may impact their evolving perceptions of telehealth. In addition, consumers' lifestyles are dynamic, undergoing continuous changes across different life stages. Consequently, a longitudinal study would yield valuable insights into the sustained use of telehealth services. In addition, future research could explore how different types of telehealth services (eg, video consultations vs remote monitoring) specifically impact adoption rates among older adults.

This study used convenient and snowball sampling to reach a hard-to-access population. Although the data represent various ethnicities and regions across Malaysia, the uneven distribution of responses may still introduce a certain level of bias. To enhance representativeness, we recommend using random or stratified sampling methods in future research.

Another limitation is the potential for self-report biases, as participants may have provided socially desirable responses rather than their true thoughts or behaviors. While we mitigated this by ensuring survey anonymity, self-report biases may still persist and should be considered when interpreting the findings. Future research should incorporate objective measures, such as tracking actual telehealth use data, to complement self-reported data and provide a more accurate assessment.

Although this study meets the sample size requirements based on power analysis using G-Power, it may not fully capture the

diversity of the older adult population, potentially limiting the generalizability of the findings. Caution is advised when applying these results to the broader older adult population. Future studies should include larger, more diverse samples across different socioeconomic backgrounds, geographic locations, and health conditions to strengthen the robustness and applicability of the findings.

Abstract

Background: Cognitive impairment, indicative of Alzheimer disease and other forms of dementia, significantly deteriorates the quality of life of older adult populations and imposes considerable burdens on families and health care systems worldwide. The early identification of individuals at risk for cognitive impairment through a convenient and rapid method is crucial for the timely implementation of interventions.

Objective: The objective of this study was to explore the application of machine learning (ML) to integrate blood biomarkers, life behaviors, and disease history to predict the decline in cognitive function.

Methods: This approach uses data from the Chinese Longitudinal Healthy Longevity Survey. A total of 2688 participants aged 65 years or older from the 2008‐2009, 2011‐2012, and 2014 Chinese Longitudinal Healthy Longevity Survey waves were included, with cognitive impairment defined as a Mini-Mental State Examination (MMSE) score below 18. The dataset was divided into a training set (n=1331), an internal test set (n=333), and a prospective validation set (n=1024). Participants with a baseline MMSE score of less than 18 were excluded from the cohort to ensure a more accurate assessment of cognitive function. We developed ML models that integrate demographic information, health behaviors, disease history, and blood biomarkers to predict cognitive function at the 3-year follow-up point, specifically identifying individuals who are at risk of experiencing significant declines in cognitive function by that time. Specifically, the models aimed to identify individuals who would experience a significant decline in their MMSE scores (less than 18) by the end of the follow-up period. The performance of these models was evaluated using metrics including accuracy, sensitivity, and the area under the receiver operating characteristic curve.

Results: All ML models outperformed the MMSE alone. The balanced random forest achieved the highest accuracy (88.5% in the internal test set and 88.7% in the prospective validation set), albeit with a lower sensitivity, while logistic regression recorded the highest sensitivity. SHAP (Shapley Additive Explanations) analysis identified instrumental activities of daily living, age, and baseline MMSE scores as the most influential predictors for cognitive impairment.

Conclusions: The incorporation of blood biomarkers, along with demographic, life behavior, and disease history into ML models offers a convenient, rapid, and accurate approach for the early identification of older adult individuals at risk of cognitive impairment. This method presents a valuable tool for health care professionals to facilitate timely interventions and underscores the importance of integrating diverse data types in predictive health models.

older adults; cognitive decline; Alzheimer disease; machine learning; blood biomarkers; disease history; Mini-Mental State Examination; MMSE; Chinese Longitudinal Healthy Longevity Survey; CLHLS

Introduction

Alzheimer disease (AD), the most prevalent form of dementia, is a progressive condition primarily characterized by memory loss [1]. It is estimated that approximately 50 million people worldwide are currently living with AD [2]. This condition not only deteriorates the quality of life for older adult individuals but also imposes significant burdens on families and health care systems, especially as the global population continues to age [3-6]. Mild cognitive impairment (MCI) is recognized as an intermediary stage between normal aging and the more severe cognitive decline observed in dementia. Early detection of MCI through diagnostic tools, such as magnetic resonance imaging (MRI), can facilitate timely interventions aimed at reducing the risk of progression to AD [7]. However, cognitive impairment, which encompasses a broader spectrum of decline, including MCI, is a critical concern that requires early identification. Predicting cognitive impairment, including MCI and other forms of decline, is essential for implementing preventive strategies and improving long-term health outcomes. Therefore, identifying individuals at potential risk for cognitive impairment is crucial.

While MRI and cerebrospinal fluid biomarkers, such as amyloid β, are significant indicators of AD [8], we aim to develop an algorithm that allows for the precise identification of individuals at risk using a more convenient and rapid approach, without relying on complex analyses like MRI or cerebrospinal fluid biomarkers. Recent studies have established a correlation between blood biomarkers and various factors, including diseases such as hypertension, diabetes, heart disease, and cerebrovascular disease, and lifestyle behaviors such as smoking, physical activity, and living conditions, with cognitive impairment [9,10]. High-dimensional data analysis has proven effective in capturing features that are crucial for identifying health issues [11,12]. Hence, the incorporation of these relevant factors into a sophisticated model allows for a practical application both in clinical settings and at home, enabling doctors or families to use existing data to train and monitor patients or older adult individuals, thereby identifying high-risk groups for further treatment and intervention.

In recent years, machine learning (ML), a branch of artificial intelligence, has been increasingly used for the prediction of disease outcome [13,14]. Unlike traditional methods that rely heavily on statistical significance, ML leverages algorithms to process existing factors and develop optimized models [15]. While there has been significant research into understanding the pathogenesis and influencing factors of MCI through ML, most of these studies have primarily focused on imaging techniques such as MRI [16]. Although MRI is a powerful diagnostic tool, its high cost and the inconvenience it poses limit its practicality for widespread use. In contrast, cognitive function assessments, such as the Mini-Mental State Examination (MMSE), offer a more accessible and feasible option for large-scale population screenings [17,18].

In this study, we used follow-up data from the Chinese Longitudinal Healthy Longevity Survey (CLHLS) collected during the years 2008‐2009, 2011‐2012 and 2014, encompassing a total of 2688 participants. Cognitive impairment was classified based on the MMSE scores, with a cutoff point set at 18, to determine cognitive status after 3 years. We included routine blood indices, lifestyle behaviors, and disease history from the baseline data in the ML model for training, aiming to predict the occurrence of cognitive impairment.

Methods

Study Participants

The cohort for this study is selected from CLHLS, which is a comprehensive longitudinal survey co-orchestrated by Peking University and the China Aging Science Research Center [19,20]. The survey targets Chinese seniors aged 65 years or older and includes detailed information about their living conditions, socioeconomic status, and health profiles [21]. The CLHLS initiates its baseline survey in 1998 and subsequently conducts follow-up surveys at regular intervals, with the relevant cohorts for this study being those from 2008‐2009, 2011‐2012, and 2014. The CLHLS study maintains ethical standards with approval from the Research Ethics Committee of Peking University (IRB00001052-13074), and all participants or their legal proxies provide written informed consent.

The initial samples from these specified years consist of 8418, 6066, and 3441 participants, respectively. Baseline subjects were screened by MMSE, and cognitive impairment was defined as an MMSE score <18 points [22]. The participants without missing data on MMSE scores at baseline and follow-up while with biomarker data were included in this study. This results in a narrowed-down research sample, with 602 participants from the 2008‐2009 cohort, 1263 from 2011‐2012, and 1116 from 2014, leaving a final sample size of 2688 subjects. Among the remaining participants, those from the 2008‐2009 and 2011‐2012 waves (n=1664) were further divided into a training set (n=1331) and an internal test set (n=333). The 1024 participants from the 2014 wave were used as a prospective validation set.

Predictors

Demographic predictors include age, gender, and BMI, calculated as weight in kilograms divided by height in meters squared (kg/m^2). Data on life behaviors and disease history are collected from the CLHLS questionnaire. Life behaviors account for living status (living alone or not), current smoking and drinking habits, exercise practices, marital status, and overall activity ability and mental health. Activity ability is assessed through activities of daily living (ADL) and instrumental activities of daily living (IADL). ADL was assessed by 6 indicators, including bathing, dressing, toileting, indoor transfer, continence, and eating. If all 6 items can be completely self-care, it means that daily life activities can take care of themselves. If

one or more items cannot be completely self-care, it means the daily life activities cannot take care of themselves completely (0=normal, 1=disability) [23,24]. IADL was assessed by 8 indicators, including visiting neighbors, going shopping, cooking a meal, washing clothing, walking continuously for 1 km at a time, lifting a weight of 5 kg, continuously crouching and standing up 3 times, and taking public transportation. If 8 items can be completed independently, such as the evaluation method of ADL, it means the instrumental daily life activities can be completed by themselves (0=normal or 1=disability) [23,25,26].

The development of the model in this study encompasses 3 categories of predictors derived from the baseline survey data: biomarkers, life behaviors, and disease history. The set of biomarkers comprises both routine blood examination indices and plasma biochemical examination indices. Routine blood indices include white blood cell count, red blood cell count, hemoglobin, erythrocyte hematocrit, erythrocyte mean corpuscular volume, erythrocyte mean corpuscular hemoglobin, erythrocyte mean corpuscular hemoglobin concentration, platelet count, plateletcrit, mean platelet volume, lymphocyte count, percentage of lymphocytes, and platelet distribution width. The plasma biochemical indices include high-density lipoprotein cholesterol (HDL), uric acid, plasma creatinine, glucose, triglyceride, total cholesterol (CHO), high-sensitivity c-reactive protein, malondialdehyde (MDA), and superoxide dismutase activity.

Mental health evaluation incorporates 7 questions, with 4 positively framed inquiries (regarding optimism, neatness, decision-making, and happiness relative to youth) and 3 negatively framed ones (concerning fear, loneliness, and feelings of decreased self-worth with age). Responses are scored on a scale, with higher scores correlating with poorer mental health. Disease history captures the presence or absence of hypertension, diabetes, heart disease, stroke, cancer, and arthritis. These multifaceted predictors collectively contribute to the ML model, providing a comprehensive profile for the assessment of cognitive impairment risk.

Data Preprocessing and Model Configuration

The data preprocessing phase involved addressing missing values and mitigating class imbalance to ensure a robust foundation for model training. Missing values in the dataset were imputed using the mean of the respective columns, which ensured completeness and preserved the statistical properties of the data [27]. In order to address the issue of class imbalance, the SMOTE (Synthetic Minority Over-Sampling Technique) was applied to the training set. SMOTE effectively generated synthetic samples for the minority class, enhancing the model's ability to learn from the imbalanced data distribution [28].

The selection of ML models was driven by a desire to compare different algorithms' performance and assess their robustness in dealing with imbalanced datasets. We chose 5 widely used algorithms: random forest (RF) [29], Extreme Gradient Boosting (XGBoost) [30], logistic regression [31], support vector machines (SVM) [32], and balanced random forest (BRF) [33]. These models were selected for their varied approaches to classification and their effectiveness in handling different types of data. RF and XGBoost are ensemble models that excel in handling high-dimensional data and capturing nonlinear relationships. Logistic regression and SVM are classic algorithms for binary classification, with SVM known for its ability to handle high-dimensional spaces effectively. The addition of BRF was made specifically to address the class imbalance issue in the RF model. The main difference between RF and BRF is how they handle class imbalance.

Each model was configured as follows:

- XGBoost (XGBClassifier): a learning rate of 0.03 and a maximum depth of 4 were chosen for the XGBoost model, with class weights incorporated to address class imbalance.
- Logistic regression: configured with a maximum of 1000 iterations and class weights set to "balanced" to account for class imbalance.
- SVM: probability estimation was enabled and class weights were balanced to ensure fairness across experiments.
- BRF: class weights were set to "balanced" to address the class imbalance within the dataset.

Outcomes

The assessment of cognitive function among participants was conducted using the MMSE, administered at both baseline and during follow-up sessions. The MMSE encompasses evaluations across various cognitive domains including orientation, registration, attention and calculation, recall, and language abilities, with a maximum achievable score of 30 points. In this study, the primary outcome for the ML model is the determination of cognitive impairment, defined as an MMSE score of less than 18 points at follow-up.

Model Construction, Evaluation, and Interpretation

The construction of each model followed a systematic approach to ensure rigorous evaluation and validation. Initially, the CLHLS 2008 - 2009 and CLHLS 2011 - 2012 datasets were merged. From this combined dataset, 1331/1664 (80%) of the data was randomly allocated as the training set, while the remaining 333/1664 (20%) was reserved as an internal test set for model evaluation. And then, the CLHLS 2014 dataset was used as a prospective validation set, with the model training based exclusively on the merged data from CLHLS 2008 - 2009 and CLHLS 2011 - 2012. Standard performance metrics—including accuracy, sensitivity, specificity, and the area under the receiver operating characteristic curve—were calculated to assess model effectiveness. All statistical analyses are conducted using Python (version 3.8; Python Software Foundation)

SHAP (Shapley Additive Explanations) [34] is a method for interpreting the output of ML models by assigning a contribution value to each feature, allowing us to understand the impact of individual predictors on a model's decision. In our study, SHAP was used to explain the predictive model for cognitive impairment in older adult individuals. SHAP values decompose the model's prediction into individual contributions from each feature, making it possible to attribute the output to the various risk factors in a transparent and interpretable manner.

Ethical Considerations

The CLHLS was approved by the Duke University Institutional Review Board (Pro00062871) and the Peking University Biomedical Ethics Committee (IRB00001052–13074). All participants provided written informed consent. The data used in this study were deidentified to protect participant privacy and confidentiality. No compensation wasprovided to participants.

Results

Participant Characteristics

Table 1 summarizes the baseline characteristics of the 2688 participants included in this study, stratified into 3 subsets: the training set (n=1331), the internal test set (n=333), and the prospective validation set (n=1024). Overall, the mean age was 79.73 (SD 10.97) years and slightly over half of the participants were male (53.24%). The mean BMI was 21.81 (SD 3.8 kg/m^2). Most participants lived with others (79.49%), did not smoke (77.79%), or drink (80.96%) at present, and had normal ADL (95.02%). Additionally, more than half (55.28%) showed abnormal mental health status, while 51.45% were married and living with a spouse. Several biochemical indicators were measured. The mean white blood cell count was 5.85 (SD 1.74×10^9)/L, red blood cell count was 4.64 (SD 1.68×10^{12})/L, and hemoglobin was 131.56 (SD 30.20) g/L. Participants had a mean HDL level of 1.31 (SD 0.38) mmol/L, and other biomarkers (eg, uric acid, creatinine, glucose, triglycerides, CHO, high-sensitivity c-reactive protein, MDA, and superoxide dismutase) were also assessed. Regarding disease history, hypertension was most prevalent (27.18%), followed by arthritis (11.31%), heart disease (8.01%), stroke (6.29%), and diabetes (2.75%). Cancer was reported by 0.42% of participants. Detailed distributions of these characteristics across the training, internal test, and prospective validation sets are presented in Table 1. A detailed flow diagram of participant inclusion and exclusion is provided in Figure 1.

Table . Characteristics of study subjects at baseline.

Predictors		Overall (n=2688)	Train set (n=1331)	Internal test set (n=333)	Prospective validation set (n=1024)
Demographics and life behaviors					
Age, year, mean (SD)		79.73 (10.97)	80.24 (11.43)	79.69 (11.6)	79.73 (10.07)

Model Performance

The performance of the ML models in predicting follow-up cognitive impairment was evaluated using 5 algorithms—RF, XGBoost, logistic regression, SVM, and BRF—on both the internal test set and prospective validation set. Each model's accuracy, sensitivity, and area under the receiver operating characteristic curve were assessed. The detailed results are presented in Table 2 and visually depicted in Figure 2. Additionally, we used the MMSE as an input for ML prediction. After testing several ML models, the overall performance remained suboptimal. For illustration, we selected 1 representative result, as shown in Table 2.

Table . The prediction results for ML[a] models.

	Internal test			Prospective validation

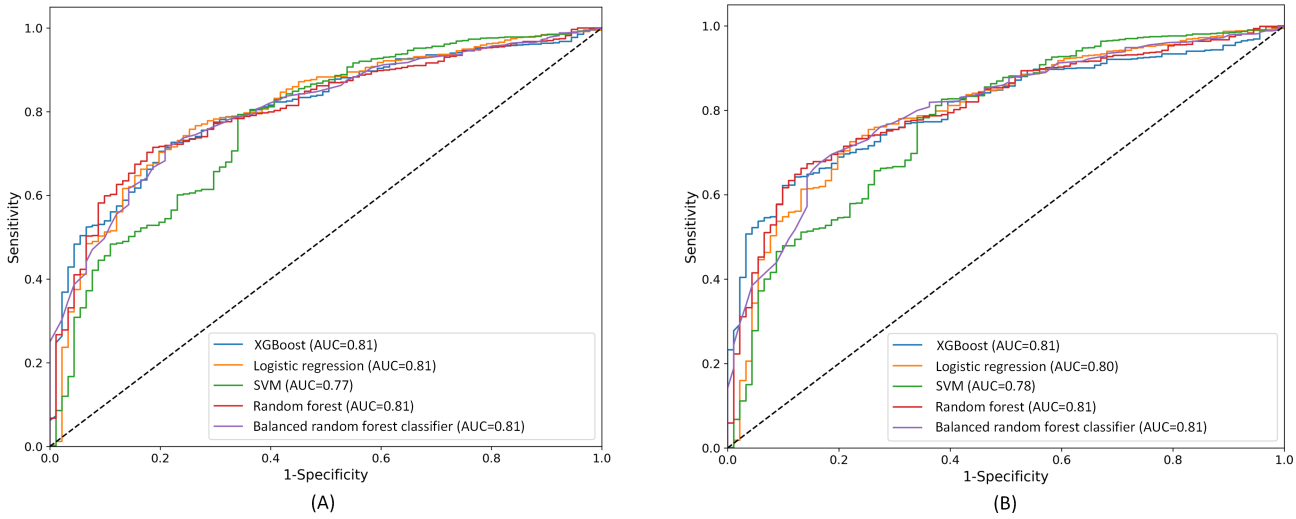
[g]N/A: not applicable.

Figure 2. ROC curves with AUC values for machine learning models: (A) internal test set and (B) prospective validation set. AUC: area under the curve; ROC: receiver operating characteristic; SVM: support vector machines; XGBoost: Extreme Gradient Boosting.



In the internal test set, the BRF achieved the highest accuracy at 88.5% but had lower sensitivity at 58%. RF and XGBoost provided balanced results with accuracies of 82.8% and 84.9% and sensitivities of 68.8% and 67.4%, respectively. Logistic regression yielded a moderate accuracy of 77.8% but the highest sensitivity at 71.5%, while SVM had the lowest performance with 69% accuracy and 68.1% sensitivity. Similar patterns were observed in the prospective validation set, with BRF at 88.7% accuracy, logistic regression reaching 74.5% sensitivity, and SVM again showing the lowest overall performance. Additionally, the performance of all ML models was superior to that of the MMSE.

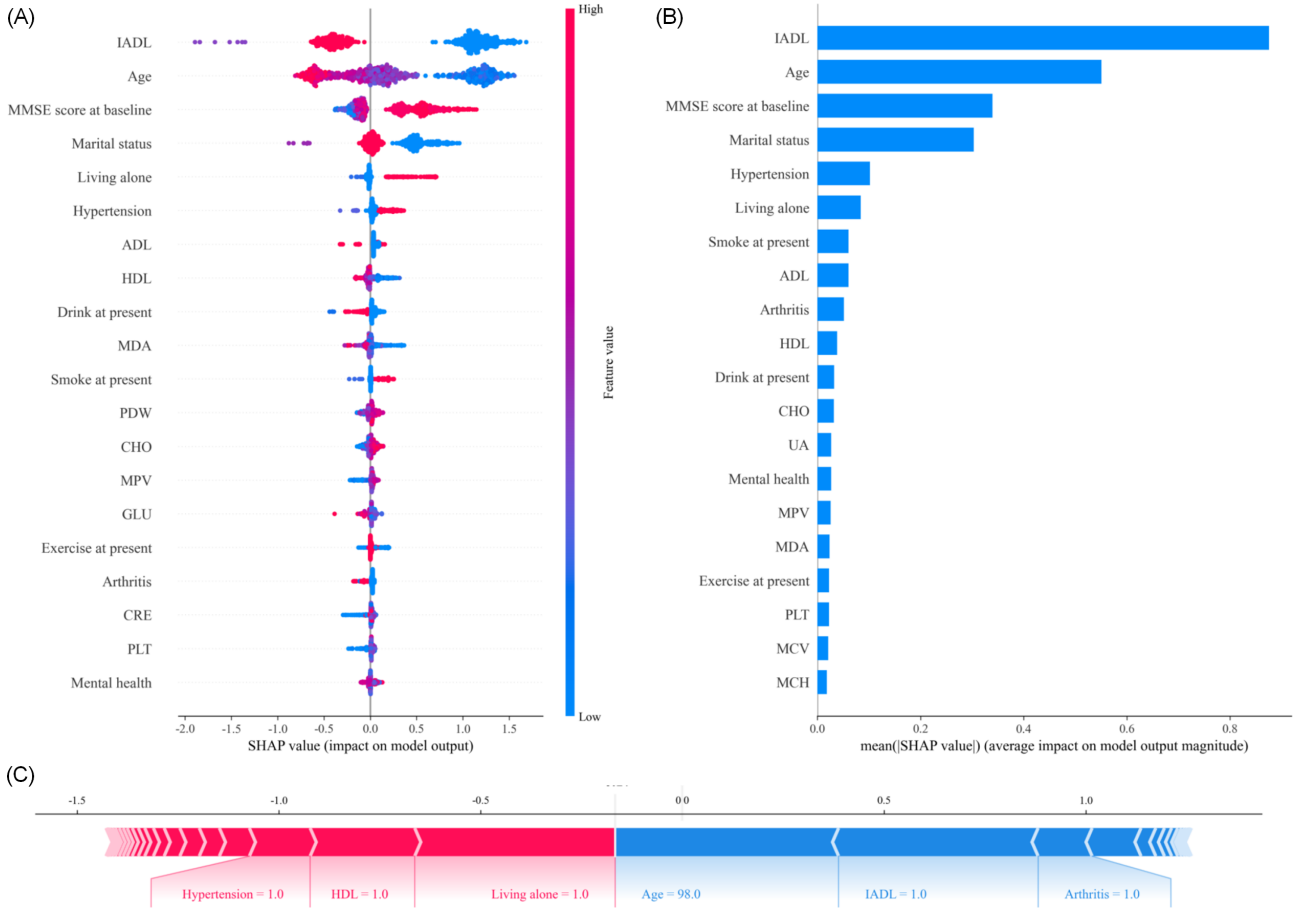
Figure 3 offers a detailed exposition of the XGBoost for cognitive impairment in older adult individuals, featuring the 20 most influential risk predictors. The model prioritizes IADL, age, and baseline MMSE scores as the top determinants, with marital status, living alone, and hypertension also providing significant predictive value. Other important factors include biological markers such as MDA and HDL, alongside lifestyle factors such as current exercise, smoking, and drinking habits.

Figure 3A illustrates the distribution of SHAP values for these predictors, indicating their impact on the XGBoost's output. In this plot, each dot represents a single instance of a feature in the dataset, and the horizontal axis shows the SHAP value of that feature. The SHAP value indicates the contribution of each feature to the model's prediction, with positive values suggesting that the feature increases the likelihood of cognitive impairment, and negative values indicating a decrease. The color of the dots, ranging from blue to red, represents the feature's value, with blue corresponding to lower values and red indicating higher values of the predictor. This color scheme helps highlight how different values of each predictor influence the model's outcome.

A high SHAP value for a given feature corresponds to a high level of importance in the predictive model. Figure 3B features a bar plot that quantifies the average impact of each predictor, measured by the mean absolute SHAP value. The length of each bar represents the average contribution of a feature to the model's output across all data points. Here, the most important features in the model—such as IADL, age, and MMSE score at baseline—are easily identified, as they have the longest bars, indicating that they have the highest average impact on the model's predictions.

Figure 3C illustrates a specific case study, showing how the SHAP values for a particular individual (in this case, an adult aged 98 years) contribute to the XGBoost's prediction of cognitive impairment. Each feature is shown with its value (eg, hypertension=1), and the arrows indicate how these values shift the model's prediction. Features such as hypertension and living alone appear to have a red color, indicating they push the prediction toward a higher risk of cognitive impairment. Similarly, age (with a value of 98) and IADL further emphasize the risk in this individual's profile. The interaction of these predictors is visualized through their SHAP values, which collectively guide the prediction model's decision, offering an individualized risk profile for this person.

Figure 3. Explanation of the interpretability of the XGBoost (Extreme Gradient Boosting) model (the best-performing model) for predicting older adult mortality. (A) and (B) show the top 20 risk predictors for prediction of cognitive impairment subjects, and (C) shows the SHAP plots of a subject. ADL: activities of daily living; CHO: total cholesterol; CRE: plasma creatine; GLU: glucose; HDL: high-density lipoprotein cholesterol; IADL: instrumental activities of daily living; MCH: erythrocyte mean corpuscular hemoglobin; MCV: erythrocyte mean corpuscular volume; MDA: malondialdehyde; MMSE: Mini-Mental State Examination; MPV: mean platelet volume; PDW: platelet distribution width; PLT: platelet count; SHAP: Shapley Additive Explanations; UA: uric acid.



Discussion

Principal Findings

This study uses the capabilities of ML to integrate a diverse set of 39 predictors for forecasting the decline in cognitive function over a 3-year period, yielding significant findings that resonate with the existing body of literature. Our ML model underscores the importance of IADL, age, baseline MMSE scores, marital status, living arrangements, hypertension, arthritis, and general lifestyle habits as pivotal factors influencing cognitive function. These determinants are consistent with findings from prior research, thereby affirming the reliability and relevance of our analytical approach [12,22].

Consistent with prior studies, advanced age has been identified as a significant risk factor for cognitive impairment [35,36]. The risk of MCI in the older adults aged 65 years or older is as high as 10% - 20% [37]. The limitation of older adult individuals' ability to perform activities, as assessed by ADL and IADL, restricts their range of activities, diminishes social interactions, and consequently reduces the cerebral stimulation necessary for maintaining cognitive functions [38,39]. Furthermore, the impact of living conditions on cognitive health

is evidenced by the predictive value of marital status and living alone [22,40-42]. Older adult individuals residing with a spouse typically exhibit healthier brain functions due to increased communication and maintenance of a normal life.

Additionally, this study underscores the detrimental effects of unhealthy lifestyle behaviors such as smoking and drinking on cognitive function [43-45], as well as the risk of cognitive impairment caused by pre-existing health conditions [46-49]. For instance, an Indian study highlighted that older smokers were 24% more likely to experience cognitive impairment compared to nonsmokers [50]. Similarly, Sabia et al [45] reported that abstaining from alcohol or consuming more than 14 units per week in middle age escalates the risk of AD. Moreover, recent research suggests that up to 3% of dementia cases could be averted by enhancing physical activity levels [51,52]. Concerning health conditions, a community-based cohort study illustrated that hypertension is associated with an increased risk of both all-cause MCI and nonamnestic MCI, with hazard ratios of 1.4 and 1.7, respectively, after age and sex adjustments [49]. Additionally, Appenzeller et al [53] found that patients with rheumatoid arthritis exhibited a significantly higher incidence of cognitive impairment compared to healthy controls.

In this study, in addition to age, lifestyle behaviors, and disease history—which can be evaluated through questionnaires or scales—biomarkers were specifically included in the ML model to enhance the predictive accuracy of clinical risk assessments for cognitive decline. Prior research has indicated that count elevated levels of specific biomarkers, including MDA, HDL, platelets, mean platelet volume, platelet distribution width, mean corpuscular hemoglobin, CHO, lymphocyte percentage, and plasma creatinine, are associated with an increased risk of cognitive decline [54-65]. For clinicians, integrating a patient's lifestyle behaviors with blood biochemical markers can aid in the assessment of cognitive function. For communities, these indicators can help identify residents who may be at high risk. For family members, this model enables the evaluation of older adult relatives who may be reluctant to acknowledge their cognitive decline, thereby facilitating timely medical intervention. The model developed in this study is versatile and offers valuable insights for the identification of cognitive impairment across various settings.

The ML model developed in this study has the potential to significantly improve clinical practice and primary care by providing a rapid, efficient, and accessible tool for identifying individuals at risk of cognitive decline. Traditional methods for cognitive function assessment, such as imaging techniques such as MRI, can be time-consuming and resource-intensive, especially in resource-limited settings. By leveraging routine data such as blood biomarkers, demographic information, and lifestyle factors, this model offers a cost-effective approach to identify individuals who may require further clinical evaluation or early intervention. In primary care settings, where health care professionals often manage large volumes of patients, the model can serve as a valuable screening tool to detect early cognitive decline and facilitate referrals for specialized care. Furthermore, by integrating this model into electronic health records, health care providers can make timely and informed decisions, improving patient outcomes through proactive management. In essence, the model has the potential to transform early detection and intervention strategies, shifting the focus toward preventative care and better allocation of health care resources.

Compared to previous studies using ML for cognitive impairment prediction, our study offers several distinct contributions. For example, while studies such as those by Hu et al [22] and Gao et al [66] have successfully developed ML models to predict cognitive impairment among Chinese community-dwelling older adult individuals, they often focused on a more limited set of predictors—typically emphasizing demographic factors and neuropsychological assessments. In contrast, our study integrates a comprehensive set of 39 predictors, including both routine blood biomarkers (eg, MDA and HDL) and detailed lifestyle and disease history data. This broader approach not only enhances predictive accuracy but also provides a rapid, cost-effective tool that can be easily applied in community and clinical settings. Moreover, while some previous work [67,68] has primarily relied on imaging data or traditional statistical methods, our use of advanced ensemble ML techniques (such as BRF and XGBoost) combined with SHAP-based interpretability offers a clearer understanding of individual risk factors. This interpretability is crucial for clinicians to tailor early intervention strategies. In summary, our study advances the field by delivering a more inclusive and interpretable model that effectively tracks cognitive decline over 3 years, thereby addressing gaps in existing research and offering tangible benefits for early detection and intervention.

Nevertheless, this study presents certain limitations that warrant consideration. Primarily, the dependence on MMSE scores as the sole measure of cognitive impairment may not fully represent the broad spectrum of cognitive health, as the MMSE mainly evaluates specific cognitive domains and does not address emotional or psychological aspects. Furthermore, there is potential bias due to the generally younger age and better overall function of this study's participants compared to those who were lost to follow-up, which could skew the results. However, the representation of the dataset at a national level does provide a measure of balance, helping to partially offset these biases.

Conclusions

In conclusion, this study validates the efficacy of a ML model integrating demographic data, lifestyle factors, and biomarkers to predict cognitive impairment in older adults. It underscores the significance of traditional risk factors such as age and daily functional abilities while highlighting the role of solitary living conditions and unhealthy habits in cognitive decline. By including a broad spectrum of biomarkers, the model enriches the predictive framework, offering clinicians, communities, and families a valuable tool for early identification and intervention in cognitive impairment, which could have far-reaching implications for public health and the well-being of the aging population.

Limitations

While the CLHLS is a large-scale longitudinal study that primarily focuses on individuals aged 65 years and older, to assess the health status and longevity of the older adult

population in China, it is important to acknowledge the limitations of the dataset concerning its representativeness. The CLHLS sample is designed to represent the health conditions of the older adult population in China, but it may not fully capture the global demographics of AD or other forms of dementia. Specifically, older adult populations in other countries or regions may differ by genetic background, lifestyle factors, and health risks, which could influence the development and progression of cognitive impairment. Future studies incorporating diverse, multinational cohorts would be beneficial in enhancing the generalizability and robustness of cognitive decline prediction models.

Acknowledgments

We thank CLHLS for providing data, and all participants for supporting this study. This study was supported by Guangzhou Science and Technology Plan Project (2024A03J1074 and 2024A03J1067) and General Project of Guangdong Provincial Natural Science Foundation (2025A1515012013).

Data Availability

The data used in this study are stored at Peking University and available upon request.

Authors' Contributions

YZ and CL contributed equally to the work. YZ, CL, HR, QW, ZL, D Li, D Liang, WT, and LL performed the data collection and analysis. YZ, CL, HR, and QW contributed to visualization. YZ and HR were responsible for data validation. YZ, CL and HR wrote this paper, and review editing was performed by HR and WC. All the authors read and approved the final paper.

Conflicts of Interest

None declared.

Abstract

Background: With changes in lifestyle, the issue of sleep disorders is becoming increasingly common. Diabetes and sarcopenia have been found to be independently associated with sleep disorders. However, fewer studies have explored the interaction between the combination of diabetes and sarcopenia at different stages and sleep disorders.

Objective: This study aimed to explore the relationship between the combination of diabetes and sarcopenia and the incidence of sleep disorders in adults aged 45 years and older.

Methods: Based on data from the CHARLS (China Health and Retirement Longitudinal Study), we selected participants with comprehensive diagnostic information on diabetes and sarcopenia from 2011 who had normal sleep duration at baseline and checked their follow-up information of sleep duration from 2013, 2015, 2018, and 2020. Diabetes was classified into diabetes (D), prediabetes (PD), and nondiabetes (ND), and sarcopenia was divided into sarcopenia (S), possible sarcopenia (PS), and nonsarcopenia (NS). The participants were divided into DS, DPS, DNS, PDS, PDPS, PDNS, NDS, NDPS, and NDNS groups. Kaplan-Meier survival curves, the log-rank test, Cox proportional hazards regression, and restricted cubic spline models were used for statistical analysis.

Results: A total of 4936 participants were included in this study. The DS group had the highest incidence of sleep disorders: 49.32%, 28.57%, 36.36%, and 80.00% in 2013, 2015, 2018, and 2020 respectively. In the crude model, compared with the NDNS group, the risk of sleep disorders was increased in the DS group (hazard ratio [HR] 1.707, 95% CI 1.196 - 2.437), PDS (HR 1.599, 95% CI 1.235 - 2.071), NDS (HR 1.465, 95% CI 1.282 - 1.674), and DPS group (HR 1.318, 95% CI 1.097 - 1.583). The risk was increased but not statistically significant in the PDPS group (HR 1.160, 95% CI 0.987 - 1.365). After adjusting for covariates, the risk of sleep disorders remained statistically significant in the DS group (HR 1.515, 95% CI 1.059 - 2.167) and was significantly higher in the PDS (HR 1.423, 95% CI 1.096 - 1.847) and NDS (HR 1.279, 95% CI 1.113 - 1.468) groups than that in the NDNS group. The nonlinear associations between appendicular skeletal muscle mass, grip strength, 5-time chair test, fasting plasma glucose, and sleep disorders were observed and described.

Conclusions: The combination of diabetes and sarcopenia significantly increases the risk of sleep disorders in adults aged 45 years and older. and the implementation of progression control of both diabetes and sarcopenia may be helpful to prevent sleep disorders in this population.

KEYWORDS

diabetes; sarcopenia; combined effect; sleep disorders; elderly; cohort study

Introduction

With changes in lifestyle, the issue of sleep disorders is becoming increasingly common. Studies report the worldwide prevalence of obstructive sleep apnea, poor sleep quality, other sleep problems, insomnia, and excessive daytime sleepiness to be 46%, 10%, 37%, 29%, and 19% respectively [1]. Even among adolescents, the prevalence of short and disturbed sleep is as high as 34.1% [2]. The impact of sleep disorders on the health of the older adults is more obvious, which can lead to cardiovascular disease [3], dementia [4], depression, and many other health problems. With the acceleration of aging, sleep disorders in older adults has become a global public health problem. A large number of studies have focused on the factors influencing sleep disorders. In addition to psychological [5], environmental [6], lifestyle [7] factors, chronic diseases, such

as diabetes [8] and sarcopenia [9] are found to be closely related to sleep disorders. According to the International Diabetes Federation report, a total of 537 million adults worldwide had diabetes in 2021, which is expected to increase by 46% to 783 million by 2045 [10]. The prevalence of diabetes in people aged ≥45 years in China is 10.6% [11], and there are significant differences between men and women, and individuals in urban and rural areas. With the increase in age, human function significantly declines, and coupled with the impact of metabolic diseases, sarcopenia is becoming more common in older adults. With a reported prevalence of 27% in individuals over 60 years of age [12], sarcopenia has become one of the common comorbidities in older adults.

Diabetes is an important factor affecting sleep disorders [13]. Studies have found a significant association between obstructive sleep apnea risk and type 2 diabetes (odds ratio [OR] 2.44, 95% CI 1.78-3.35; *P*<.001) [14]. Compared with patients without diabetes, both patients with type 1 (hazard ratio [HR] 1.41, 95% CI 1.37-1.46,) and type 2 diabetes (HR 1.40, 95% CI 1.37 - 1.44) have a significantly increased risk of sleep disorders [15]. In addition, studies have shown that sarcopenia is a chronic disease that induces sleep disorders [16], and people with both sarcopenia and diabetes have a significantly increased risk of sleep abnormalities [17]. Even self-reported sleep duration may provide the possibility for early prediction of sarcopenia. These findings suggest a complicated relationship between diabetes, sarcopenia, and sleep disorders.

However, these existing studies have not elucidated the risk of sleep disorders in populations with comorbid diabetes and sarcopenia; most studies have analyzed the relationships between diabetes and sleep disorders, as well as the impact of sarcopenia on sleep disorders. Another important issue is that both diabetes guidelines and the expert consensus on sarcopenia emphasize prediabetes and possible sarcopenia, which are similar to large icebergs beneath the surface—and their contribution to sleep disorders also warrants attention. With aging, the prevalence of diabetes and sarcopenia gradually increases in the older population, which prompts us to consider whether an interaction between diabetes and sarcopenia at different stages significantly increases the risk of sleep disorders. Previous studies have mostly explored the relationship between sarcopenia, diabetes, and sleep disorders using a cross-sectional design. On the one hand, there is a lack of evidence from longitudinal cohort designs; on the other hand, the interaction of the risk between diabetes and sarcopenia at different stages and sleep disorders has not been elucidated. Based on this scientific question, the present study used the China Health and Retirement Longitudinal Study (CHARLS) to analyze the impact of the interaction of diabetes and sarcopenia on the occurrence of sleep disorders over four longitudinal follow-up visits (ie, 2013, 2015, 2018, 2020) from the 2011 baseline population, to provide a reference for the prevention and treatment of sleep disorders in adults aged ≥45 years.

Methods

Participants and Study Design

The participants for this study were derived from the CHARLS, a nationally representative longitudinal survey initiated in 2011. It covered 150 county-level units, 450 village-level units, and 10,257 households across 28 provinces. These participants were followed up every 2 to 3 years. CHARLS covers basic personal information, household structure, health status, physical measurements, health service utilization, health insurance, and basic community characteristics. Four waves of follow-up data collection have been completed so far, and detailed information on CHARLS has been published [18].

Data were collected from CHARLS during 2011 - 2020. All information related to diabetes, sarcopenia, and sleep disorders among participants aged ≥45 years could be downloaded from 2011, 2013, 2015, 2018, and 2020.

We selected participants according to the following steps and excluded based on the following criteria: (1) lack of age information or age<45 years in 2011; 2) missing height and weight measurements at baseline; (3) height and weight data beyond mean (3 SD); (4) missing gender information; (5) missing sarcopenia-related information; (6) missing FPG (fasting plasma glucose) information; (7) FPG <3.9 mmol/L, (8) no sleep status at baseline, (9) nightly sleep duration <6 or >8 hours; (10) questionnaire lacked diabetes self-report information, (11) normal FPG but choosing a self-reported diagnosis of “diabetes or high blood sugar” for the question “Have you been diagnosed with by a doctor?”.

Subsequently, all the participants selected at baseline were matched by ID to the database of 2013, 2015, 2018, and 2020, respectively; those without necessary information about sleep duration were excluded. Only the first record of occurrence of sleep disorder was retained, if one ID was found repeatedly across years.

Measures

The measurements of exposure variables (ie, diabetes, sarcopenia), outcome variables (ie, sleep disorder, change of sleep duration or status), and covariates (ie, age, gender, education level, habitation, current marital status, current smoking, and drinking status) were respectively assessed across the cohort at each survey wave.

Assessment of Diabetes

All participants were classified as having diabetes, prediabetes, and nondiabetes according to the Guidelines for the Prevention and Treatment of type 2 Diabetes Mellitus in China (2020 edition) [19]. Since only FPG in venous blood was measured in the CHARLS, the diagnosis in this study was based only on FPG values. A venous FPG value ≥7.0 mmol/L was classified as diabetes, FPG ≥6.1 mmol/L and <7.0 mmol/L as prediabetes, and FPG <6.0 mmol/L as nondiabetes. Although the baseline survey included the question “Have you been diagnosed with by a doctor?”, the participants answering “diabetes or high blood sugar, (including impaired glucose tolerance and elevated fasting

blood sugar)," were excluded, as it was not possible to distinguish between diabetes and prediabetes.

Assessment of Sarcopenia

The Asian Working Group for Sarcopenia: 2019 Consensus Update on Sarcopenia Diagnosis and Treatment (AWGS 2019) was used to assess the status of the sarcopenia and classify participants into sarcopenia, possible sarcopenia, and nonsarcopenia groups. The average of maximum values of handgrip strength was measured using either or both hands to evaluate the skeletal muscle strength. According to AWGS 2019, the threshold for low handgrip strength is <18 kg for women and <28 kg for men. The 5-time chair stand test was used to evaluate physical performance of the participants; a time ≥12 s of the 5-time chair stand test was defined as low physical performance. Individuals who could not complete the test were excluded. The muscle mass of the participants was evaluated using a previously validated formula [20]:

ASM=0.193×body weight(kg)+0.107×height(cm)−4.157×sex(1=male, 2=female)−0.037×age(years)−2.631

Following the estimation of appendicular skeletal muscle mass index (ASM) using the above formula, the appendicular skeletal muscle mass index (ASMI) was calculated using the ASM divided by the square of height in meters (ASMI = ASM/height^2 m^2). Therefore, the cut-off values for ASMI used in this study were based on the percentile value of the lowest 20% of the study population; low muscle mass was defined as ASMI <7.05 kg/m^2 for men and <5.36 kg/m^2 for women. Sarcopenia was diagnosed if muscle mass, muscle strength, or physical performance were low, and possible sarcopenia was diagnosed if muscle strength or physical performance was low.

Covariates

Based on the literature review, some common factors correlated with sleep disorders, including demographic factors (eg, age and gender), area of residence (ie, city or rural), current marital status (ie, married or unmarried), and education level with a cut-off of junior high school graduation were selected as covariates to divide the participants into two groups. Health–related factors included current smoking and alcohol consumption status.

Statistical Analysis

The categorical variables such as gender, education level, and habitation were expressed as percentages. The χ^2 test was used for comparison between groups and Fisher exact test was used for analyses when the χ^2 test was not appropriate. For quantitative indicators such as age, FPG, and muscle mass index, the mean (SD) was used for normally distributed variables. When the variables were not normally distributed, median with interquartile range was used calculated. The 2-tailed *t* test, ANOVA, or Kruskal-Wallis tests were used for comparison among groups, as appropriate. Kaplan-Meier survival analysis and log-rank test were used to compare the incidence of sleep disorders. Based on the different adjustment covariates, three Cox proportional hazards regression models were used to analyze the combined effect of diabetes and sarcopenia on sleep disorders. The restricted cubic spline (RCS) models were used to analyze the exposure-response and nonlinear relationships between FPG, muscle mass index, grip strength, 5-time chair stand test, and sleep disorders. Microsoft Excel (2021), SPSS software (version 27.0; IBM Corp) and R software (version 4.3.2; R Foundation for Statistical Computing) were used to conduct data collation, statistical testing, and RCS modelling respectively. A $P<.05$ was considered statistically significant.

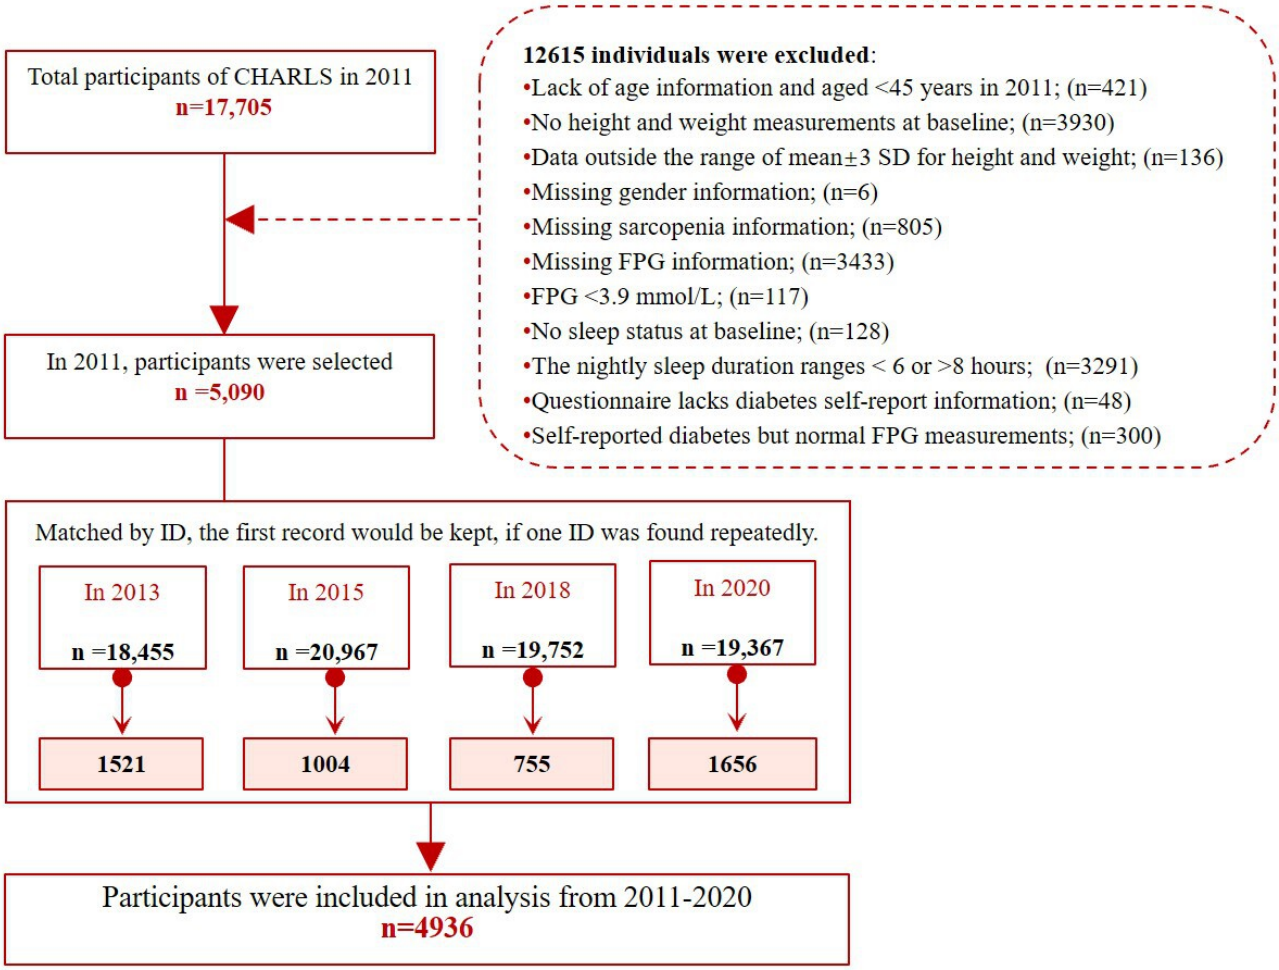
Ethical Considerations

In this study, all data were extracted from CHARLS, which received approval from Peking University Biomedical Ethics Committee (IRB00001052-11015) prior to conducting the original field investigation and all the participants had signed the informed consent form before enrollment. The secondary analysis was approved and anonymized data was used for analysis.

Results

A total of 17,705 participants were included at baseline. Of these, 12,615 were gradually excluded based on the exclusion criteria, and matched with follow-up data from 2013, 2015, 2018, and 2020 according to the participant ID. The first occurrence of sleep disorders was retained in the database. Finally, 4936 participants were included in the analysis (Figure 1).

Figure 1. The flow chart of screening for enrolled individuals. CHARLS: China Health and Retirement Longitudinal Study; FPG: fasting plasma glucose.



A total of 4936 participants were selected and followed up on their sleep during 4 follow-up visits from 2011 to 2020, including 2427 male (49.2%) and 2509 female (50.8%) participants. Further comparison of the combination of diabetes and sarcopenia at different stages—NDNS, NDPS, NDS, PDNS, PDPS, PDS, DNS, DPS, and DS were statistically significant for age, sex, marital status, place of residence, education level, smoking, alcohol consumption, review status, weight, grip strength, skeletal muscle mass, 5-time chair stand test, and blood glucose levels *(*all *Ps*<.05; Table 1).

Based on survival analysis, it was observed that with the change in follow-up time, there was a significant difference in the incidence of sleep disorders among all groups (χ^{28}=73.486, *P*<.001; Figure 2). In 2020, the DS group had the highest incidence of sleep disorders (80. and the incidence in the DPS, PDS and NDS groups reached 52.00%, 50.00%, and 48.78%, respectively; whereas, the incidence of sleep disorders was the lowest in the NDNS group (36.02%). Furthermore, the incidence of sleep disorders in the DS group was 49.32%, 28.57%, 36.36%, and 80.00% in 2013, 2015, 2018, and 2020, respectively, showing a significantly increasing trend. Significant differences were also observed between men and women, and the incidence of short sleep duration (<6 hours) and long sleep duration (>8 hours), as shown in Figure 3.

Figure 2. The incidence of sleep disorders of the co-exposure of diabetes and sarcopenia at different stages. In the diabetes group, (+) represents diabetes, (±) represents prediabetes, and (-) depicts nondiabetes. In the sarcopenia group, (+) represents sarcopenia, (±) indicates possible sarcopenia, and (-) depicts nonsarcopenia.

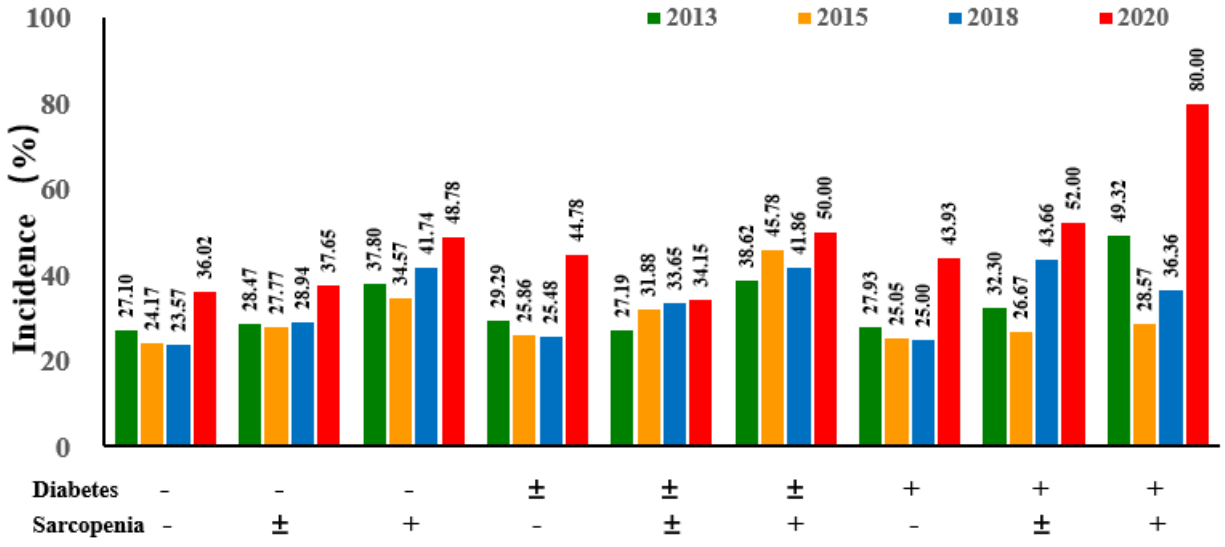

Figure 3. Incidence of sleep disorders related to co-exposure of diabetes and sarcopenia among groups. Follow-up time depicts the number of years of follow-up in 2013, 2015, 2018, 2020, respectively. χ^2 indicates the statistic from the log-rank test. NDNS: Nondiabetes and Nonsarcopenia, NDPS: Nondiabetes and Possible Sarcopenia, NDS: Nondiabetes and Sarcopenia, PDNS: Prediabetes and Nonsarcopenia, PDPS: Prediabetes and Possible Sarcopenia, PDS: Prediabetes and Sarcopenia, DNS: Diabetes and Nonsarcopenia, DPS: Diabetes and Possible Sarcopenia, DS: Diabetes and Sarcopenia; SD: sleep disorders (including sleep duration <6h and >8h); <6 hours: sleep duration at the final follow-up was <6 hours; >8 hours: sleep duration at the final follow-up was >8 hours.

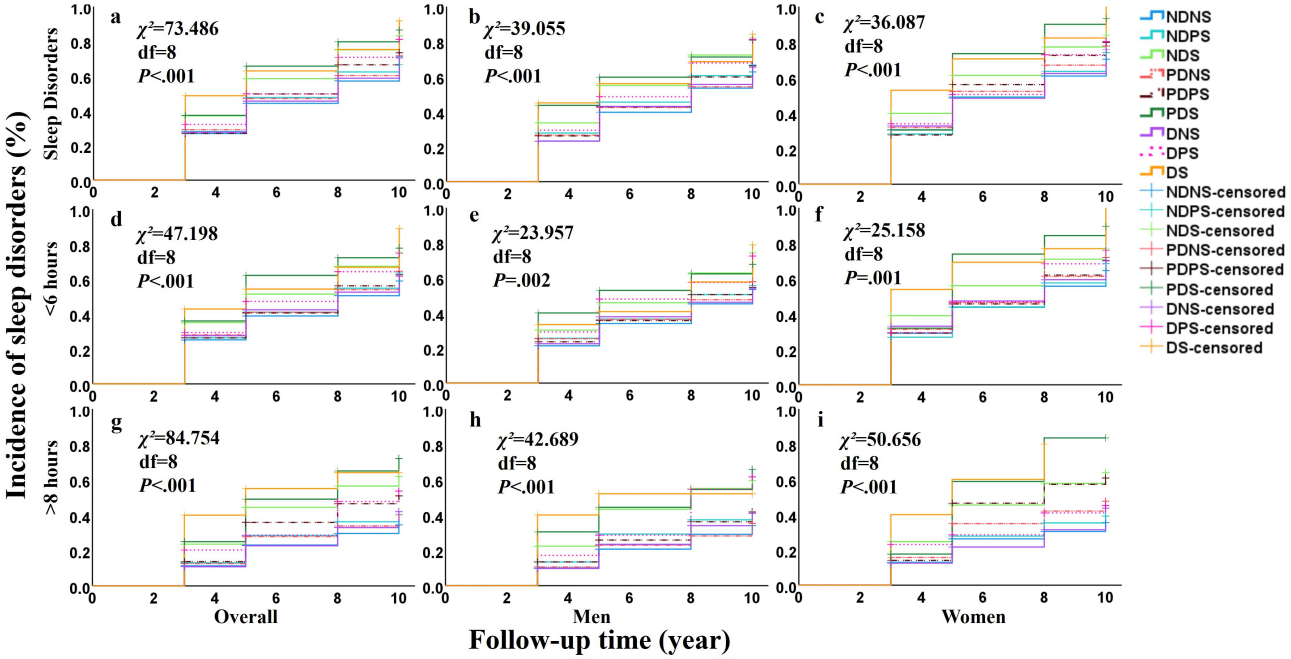

According to Cox regression analysis, there was a significant association between the combined status of diabetes mellitus, sarcopenia, and sleep disorders. In Model 1, no covariates were adjusted, compared with the NDNS group, the risk of sleep disorders was increased in the DS group (HR 1.707, 95% CI 1.196 - 2.437, *P*=.003), PDS (HR 1.599, 95% CI 1.235 - 2.071, *P*<.001), NDS (HR 1.465, 95% CI 1.282 - 1.674, *P*<.001), and DPS (HR 1.318, 95% CI 1.097 - 1.583, *P*=.003). The risk was increased but not statistically significant in the PDPS group. After adjusting for the variables (Model 3), the risk of sleep disorders in the DS group (HR 1.515, 95% CI 1.059 - 2.167; *P*=.02) was still statistically significant, and the risk in the PDS (HR 1.423, 95% CI 1.096 - 1.847; *P*=.008) and NDS (HR 1.279,95% CI 1.113 - 1.468; *P*<.001) groups were significantly higher than that in the NDNS group (Table 2).

Table . Association between sleep disorders and co-exposure to diabetes and sarcopenia at different status. Symbols indicate existing condition: diabetes (+), nondiabetes (–), prediabetes (±) in the diabetes group, and sarcopenia (+), possible sarcopenia (–), and no sarcopenia (±) in the sarcopenia group.

[a]Model 1 represents no covariates were adjusted.

[b]HR: hazard ratio.

[c]Model 2 represents adjusting for gender and age.

[d]Model 3 represents adjustment for gender, age, education, current marital status and habitation, smoking, and drinking.

[e]Sleep disorders including sleep duration <6 hours and >8 hours.

[f]Decreased indicates difference of sleep duration between baseline and follow-up <0.

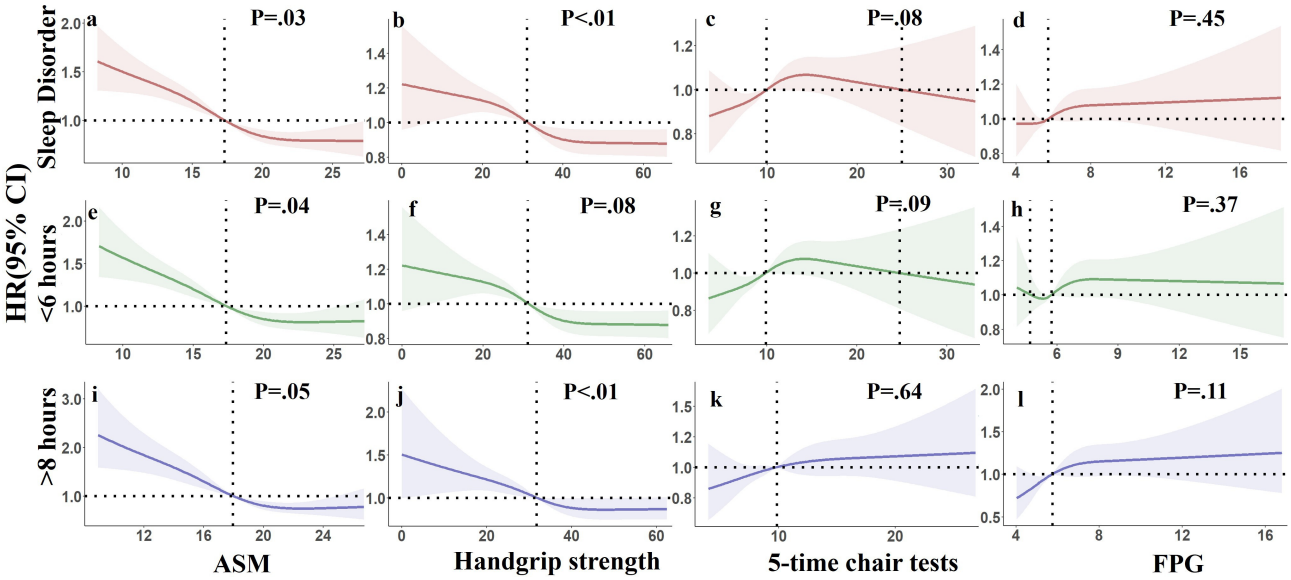
[g]Increased indicates the difference of sleep duration between baseline and follow-up >0.

After a stratified analysis of sleep duration (ie, <6 hours and >8 hours), the risk of short sleep duration (< 6 hours) was significantly increased in the DS group without adjusting for variables (Model 1: HR 1.713, 95% CI 1.123 - 2.612) and remained statistically significant after adjusting for variables (Model 3: HR 1.546, 95% CI 1.010 - 2.365). The risk of long sleep duration (> 8 hours) was significantly increased in the DS group without adjusting for variables (Model 1: HR 2.739, 95% CI 1.414 - 5.306), which remained statistically significant after adjusting for variables (Model 3: HR 1.970, 95% CI 1.011 - 3.840; Table 2).

To analyze the changes in sleep duration, we stratified participants based on the difference in sleep duration between the final follow-up and baseline. If the difference was <0, it was defined as “Decrease,” while a difference >0, was defined as “Increase in sleep duration.” Cox regression analysis revealed that the risk of “Decrease” in sleep duration in the NDS group without adjusting for the variable (Model 1) is significantly higher (HR 1.735, 95% CI 1.261 - 2.386), and this remained statistically significant after adjusting for covariates (Model 3: (HR 1.525, 95% CI 1.105 - 2.104). After adjusting for covariates, the risk of “Increase” in the PDS (Model 3: HR 1.697, 95% CI 1.185 - 2.429) and NDS (Model 3: HR 1.385, 95% CI 1.119 - 1.713) groups also increased significantly (Table 2).

To further assess the relationship between diabetes, sarcopenia, and sleep disorders, the RCS model was used to describe important factors related to sarcopenia—ASM, handgrip strength, 5-time chair stand test performance—and the exposure response relationship between FPG levels, and sleep disorders. Figure 4 illustrates these association of sleep disorders with ASM (χ^2=45.04, P<.001, P for nonlinearity=.0284), handgrip strength (χ^2=16.62, P<.008, P for nonlinearity<.0017), and 5-time chair stand tests (χ^2=8.78, P=.03, P for nonlinearity=.0806). A nonlinear correlation was observed between sleep disorders and both ASM and handgrip strength. The relationship between FPG and long sleep duration (>8 hours) was also significant (χ^2=9.44, P=.02, P for nonlinearity=.10731).

Figure 4. Exposure-response relationship among diabetes, sarcopenia, and sleep disorders.. The restricted cubic spline (RCS) was used to model expose-response curves after adjusting for factors including gender, age, education, current marital status, and habitation, smoking, and drinking. ASM: appendicular skeletal muscle mass; FPG: fasting plasma glucose; HR: hazard ratio; SD: sleep disorders; <6 h: sleep duration was <6 hours; >8 h: sleep duration was >8 hours.



Discussion

With increasing age, the issue of sleep disorders in older adults is becoming more severe [21]. Common chronic conditions including diabetes mellitus and sarcopenia which are highly prevalent could affect sleep quality. In particular, prediabetes and possible sarcopenia are now being diagnosed at an early age. If this status is not addressed during reversible stages, the risk of sleep disorders in adults aged ≥45 years is even more severe. Although studies have reported a relationship between diabetes [22] or sarcopenia [23] and sleep disorders, there is a lack of studies on the relationship between co-exposure at varying stages of diabetes and sarcopenia. This study found that participants with diabetes and sarcopenia had the highest risk of sleep disorders; groups with prediabetes and sarcopenia, nondiabetes with sarcopenia, and diabetes with possible sarcopenia had a significantly higher risk of sleep disorders. Additionally, there was an exposure-response relationship between ASM, handgrip strength, 5-time chair test, FPG levels, and sleep disorders. These findings can provide a reference for the prevention of sleep disorders in adults aged ≥45 years and the development of early screening and personalized intervention.

Diabetes, as a chronic disease with high incidence in older adults, is an important factor contributing to sarcopenia [24] and sleep disorders [25]. Our findings showed that participant groups with both diabetes and prediabetes have an increased risk of sleep disorders. This may be explained by the following mechanisms. On one hand, diabetes can affect the function of the hypothalamic-pituitary-adrenal axis, resulting in abnormal secretion of hormones such as cortisol [26]. The rhythm of these hormones can affect the sleep-wake cycle, leading to the sleep disorders [27]. On the other hand, hyperglycemia may lead to the secretion of melatonin, which plays a key role in regulating sleep rhythms [28]. Its altered secretion can lead to difficulty falling asleep and poor sleep quality [29]. In addition, patients with sarcopenia are prone to muscle fatigue and damage due to the loss of mass and strength of several muscles [30]. During sleep, changes in body posture may strain already fragile muscles, causing pain and discomfort, resulting in sleep disruption. Muscle strength in the chest and abdomen decreases in patients with sarcopenia, resulting in decreased respiratory function [31]. During sleep, weakness in respiratory muscles may cause poor breathing, snoring and even apnea, thus interfering with sleep [32]. It is also important to note that diabetes can cause sarcopenia. Long-term hyperglycemia may lead to peripheral neuropathy [33], causing a decrease in muscle blood supply, affecting the nutrition and innervation of nerves to muscles [34], which in turn leads to muscle waste atrophy. Patients with diabetes and prediabetes have widespread insulin resistance, which blocks insulin signaling pathways such as PI3K/Ak [35] and Ras-MAPK [36], thus cannot effectively promote the uptake of amino acids by muscle cells, thereby inhibiting the synthesis of muscle proteins; this results in a decrease in muscle mass. These mechanisms reveal the relationship between FPG, ASM, handgrip strength, 5-time chair stand test, and sleep disorders, as identified by the RCS model.

This study found that participants with comorbid diabetes and sarcopenia had the highest risk of sleep disorders, and the groups with prediabetes and sarcopenia, nondiabetes and sarcopenia, and diabetes with possible sarcopenia also had a significantly higher risk of sleep disorders. The potential mechanisms of sleep disorders caused by the comorbidity of diabetes and sarcopenia may be related to the following: (1) patients with diabetes already have abnormal blood sugar regulation; sarcopenia will further affect the uptake and utilization of glucose by muscles, resulting in more frequent and difficult-to-control blood sugar fluctuations [37]. This may result in the superposition of metabolic disorders, triggering energy metabolism imbalance [38], making the body unable to obtain enough energy at night to maintain normal physiological

functions and sleep status. (2) Neuropathy caused by diabetes, including damage to peripheral and autonomic nerves can affect the sensory and motor functions of muscles [39]. Sarcopenia aggravates muscle weakness and atrophy, further impairing the function of the neuromuscular junction [40]. This neuromuscular dysfunction can lead to nocturnal muscle twitches, spasms, or pain that interfere with sleep. Autonomic dysfunction is common in both diabetes and sarcopenia; it affects the regulation of the cardiovascular and respiratory systems, resulting in abnormal fluctuations in blood pressure and heart rate at night, poor breathing, and increases the risk of sleep disruption [41]. Both diabetes and sarcopenia are associated with abnormal hormone secretion [42], which may lead to reduced secretion of testosterone, estrogen, and insulin-like growth factor 1 (IGF-1) among others. Significant gender differences were observed in our study, which may further support this phenomenon. Furthermore, diabetes and sarcopenia are both accompanied by chronic inflammation and increased levels of oxidative stress [43]. Tumor necrosis factor α (TNF-α), interleukin 6 (IL-6) promote muscle catabolism and may affect the central nervous system function, resulting in disorders in sleep regulation centers. Reactive oxygen species produced during oxidative stress can damage both neural and muscular systems, aggravate physical discomfort, and then affect sleep [44].

Our findings have several implications. First, special attention should be paid to adults aged ≥45 years with sleep disorders. To improve sleep duration and quality, it is necessary to effectively manage diabetes, perform physical exercises to improve muscle mass and function, and continuously monitor sleep quality. Second, for people with prediabetes or possible sarcopenia, early intervention should be carried out to prevent the occurrence of diabetes or sarcopenia, which can effectively reduce the risk of sleep disorders. Third, the community should build appropriate sports facilities and provide an environment that promotes physical exercise to improve the health of residents. In addition, regular screening for diabetes and sarcopenia should be implemented to detect patients with diabetes and sarcopenia at an early stage, and comprehensive interventions should be actively used to prevent sleep disorders.

The advantages of this study include the following aspects. It is a large-scale, nationally representative cohort study of community residents, using survival analysis and Cox regression models to explore the co-exposure of diabetes and sarcopenia—as well as the impact of prediabetes with latent risk and possible sarcopenia—on sleep duration and sleep status. However, there are also a few limitations within our study: First, due to limitations in the CHARLS data, we could not fully explore the relationship between diabetes status, progression trends in sarcopenia from 2011 to 2020, and specific types of sleep disorders. Our analysis was limited to examining the impact of diabetes and sarcopenia status on sleep disorders in 2011; the relationship between the factors affecting progression and sleep disorders is complex. Concurrently, due to limited data, we included a smaller number of participants aged ≥75 years in our study, and the differences in population distribution across age groups may limit the extrapolation of our findings. Second, prediabetes is an intermediate stage that can revert toward normoglycemia and diabetes. Therefore, our study only analyzed the effect of prediabetes exposure at baseline on sleep disorders. Since the CHARLS did not provide data on FPG levels for the four follow-up waves , it was impossible to explore the role of changes in prediabetes status on sleep disorders. However, our findings still suggest that patients with prediabetes were at an increased risk of sleep disorders. Therefore, family-based and both individual health education [45], and community-level behavioral interventions play an important role in the prevention of sleep disorders [46]. Fourth, there is a mutual relationship among diabetes, sarcopenia, and sleep disorders. Although both diabetes and sarcopenia can lead to sleep disorders, the interaction between diabetes and sarcopenia on sleep disorders could not be analyzed due to lack of sufficient data. Fifth, this study found a potential relationship between the co-exposure to various diabetes and sarcopenia statuses, and sleep disorders. Diabetes and sarcopenia may have a synergistic effect on the occurrence of sleep disorders; however, causality cannot be based solely on our findings. Future research should focus on the progression and changes of diabetes, sarcopenia, and sleep disorders, including sleep efficiency [47] to explore the relationship among them.

In conclusion, this study found that diabetes combined with sarcopenia in adults aged 45 years and older may increase the risk of sleep disorders. To reduce this risk, it is essential to implement effective disease management for both diabetes and sarcopenia, and to further evaluate joint intervention measures for individuals with prediabetes or possible sarcopenia.

Acknowledgments

This study was funded by the Beijing High level Public Health Technical Talents Training Plan (2022-1-005, Key DisciplineMember-02- ‐ 44). We are grateful to the CHARLS (China Health and Retirement Longitudinal Study), which provided data for this research. We also thank all the participants, staff members, volunteers devoted to the CHARLS project.

Abstract

Background: Over half the people over 60 years of age experience cognitive impairment, with limited treatment options, making it crucial to identify risk factors. Studies have examined the association between sarcopenia and cognitive impairment; however, the evidence is inconclusive and cannot be used to make causal inferences.

Objective: This study aims to appraise the causal association of sarcopenia with cognitive impairment by triangulating the data from a cohort study and Mendelian randomization (MR) analysis.

Methods: Using UK Biobank data, we first examined the associations of sarcopenia and its indices (appendicular lean mass [ALM], handgrip strength, and gait speed) with cognitive function (fluid intelligence and prospective memory) by using mixed-effects regression models. Then, we explored the causal associations of genetically predicted sarcopenic indices with cognitive function through a 2-sample MR, and examined potential mediation by omega-3 fatty acids, vitamin D levels, physical inactivity, falls, frailty, sleep disorders, anxiety, depression, stroke, metabolic syndrome, and type 2 diabetes.

Results: A total of 34,457 participants, with a mean age of 56.4 (SD 7.6) years, 51.1% (n=17,620) of which were female, completed baseline cognitive tests between 2006 and 2010 and attended at least 1 follow-up visit in 2012, 2014, or 2019, and were included in the observational analysis. The cohort study revealed that sarcopenia was significantly associated with cognitive impairment, which was evidenced by reduced fluid intelligence scores (β=−0.91, 95% CI −1.68 to −0.15; *P*=.02). Each of the sarcopenic indices also exhibited significant associations with either fluid intelligence or prospective memory (all *P*<.05). MR analyses yielded compelling evidence of positive associations between the genetically predicted increases in ALM (β=0.09, 95% CI 0.07-0.12; *P*<.001), handgrip strength (β=0.18, 95% CI 0.08-0.29; *P*<.001) and gait speed (β=0.78, 95% CI 0.53-0.29; *P*<.001) and improved cognitive function. The effects of ALM and handgrip strength on cognitive function were partially mediated by genetically predicted physical activity, with indirect effects of 0.01 (95% CI 0.00-0.02) for ALM and 0.02 (95% CI 0.00-0.05) for handgrip strength.

Conclusions: Our study suggests that sarcopenia is a potential causal risk factor for cognitive impairment, with physical activity acting as a modifiable mediator in this relationship.

Introduction

An impairment in cognitive function is a neurodegenerative process that affects 10% - 20% of people aged 65 years and older [1], and that can lead to adverse health consequences, including diminished quality of life [2] and increased risk of hospitalization [3], as well as mortality [4]. However, by the time of diagnosis, the pathological changes related to cognitive impairment have often become irreversible. The available treatments are limited and target symptoms, with very low efficacy [5]. Thus, identifying the potential factors for predicting the risk of subsequent cognitive impairment has become a public health priority [6,7]. Such measurable indices can help recognize high-risk populations to explore potential disease-modifying therapies.

Sarcopenia, characterized by accelerated loss of muscle mass and deterioration in function, is a prevalent skeletal muscle disorder in the elderly [8]. As predicted by statistics, about 2 billion individuals globally will be affected by sarcopenia by 2050 [9]. Through the progression of physical inactivity, patients with sarcopenia tend to experience an increased risk of disability, which has been associated with cognitive impairment due to its impact on neurogenesis and cerebral blood vessel formation [10,11]. Previous cohort studies have reported a possible relationship between sarcopenia and cognitive impairment [12-17]. However, this relationship is still not fully understood and may even be controversial [18]. Some studies have even rejected any significant association between sarcopenia itself [19], or its related indices [20,21] and cognitive impairment. Discrepancies in definitions of sarcopenia and sample sizes among studies may underlie these conflicting outcomes. Hence, a more intricate exploration is warranted to establish the precise link between sarcopenia and cognitive impairment.

Furthermore, current available human evidence on such association is mostly based on observational research, and therefore cannot be relied on to derive causal inferences due to inherent limitations (eg, reverse causality and unmeasured confounders) [22]. Examining the causal association between sarcopenia and cognitive impairment and identifying potentially modifiable intervention targets along the causal pathway is of important public health significance for preventing cognitive impairment [18]. Mendelian randomization (MR) is a method that involves using genetic variants as proxies for the targeted exposure. Since, genetic variants are conditional on parental genotypes and randomly allocated at conception, the results from MR studies are more resistant to reverse causality and confounding than those derived from conventional observational studies [22].

Using a large population-based cohort, this study was initiated by evaluating the observational data that links the consensus definition of sarcopenia, which was established by the European Working Group on Sarcopenia in Older People in 2019 (EWGSOP2), as well as its 3 defining indices (ie, appendicular lean mass [ALM], handgrip strength, and gait speed), to the risk of cognitive impairment. To best assess causality, we performed multiple MR analyses to explore the potential causal association between sarcopenia and cognitive function. Subsequently, we further used MR mediation analysis to examine the degree to which 11 putative mediators (ie, omega-3 fatty acids, vitamin D levels, physical inactivity, falls, frailty, sleep disorders, anxiety, depression, stroke, metabolic syndrome, and type 2 diabetes) may impact the effects of sarcopenia, to identify potential intervention targets in the causal pathway. This study aims to elucidate the causal relationship between sarcopenia and cognitive impairment while identifying actionable intervention targets within the causal pathway through the evaluation of these mediators.

Methods

Study Design

We examined the associations of sarcopenia and its indices with cognitive function in a cohort of approximately 35,000 participants from the United Kingdom Biobank. We then conducted multiple MR analyses to explore the potential causal relations between sarcopenic indices (ie, ALM, handgrip strength, and gait speed) and cognitive function. Finally, we used mediation MR analysis to quantify to what extent physical inactivity, depression, anxiety, falls, frailty, and vitamin D use mediated the effects of sarcopenic indices on cognitive function. This research has been conducted using the UK Biobank Resource under Application 77,646.

Cohort Study

Study Participants

The UK Biobank is a comprehensive prospective cohort that enrolled ≥500,000 participants aged 40 - 69 from 22 centers over the United Kingdom between 2006 and 2010. Neuropsychological tests were performed to assess cognitive function assessment in a subset of participants at baseline as well as 3 subsequent visits via a touch screen. Approximately 170,000 individuals participated in the baseline visit (2006 - 2010), and ~20,000, ~60,000, and ~8000 individuals participated in the first (2012 - 2013), second (2014+), and third (2019+) follow-up visits, respectively. For each follow-up visit dataset, consistent diagnostic criteria were applied for both sarcopenia and cognitive function. In our analysis, we included 35,000 participants who underwent cognitive function tests at baseline and had at least one subsequent follow-up visit (see Figure S1 in Multimedia Appendix 1).

Exposure and Outcome Measurements

Sarcopenia was defined according to the EWGSOP2, which uses the detection of low grip strength and low muscle mass to confirm sarcopenia, with poor physical performance indicating severe sarcopenia [23]. ALM was evaluated by bioelectrical impedance analysis with a Tanita BC418MA body composition analyzer and expressed in kilograms. We used the cut points as recommended in the EWGSOP2 definition of <7 kg/m^2 in men and 5.5 kg/m^2 in women. Grip strength was measured with a hydraulic handheld dynamometer (Jamar J00105). Specifically, 3 measurements were recorded for the maximum strength of both hands, and the highest values were used for analysis, expressed in kilograms. The cut-points for low grip strength

recommended by EWGSOP2 were <27 kg in men and <16 kg in women. Gait speed was acquired directly from the participants through the question "How would you characterize your usual walking speed?" (options: "slow" [<3 miles per hour], "steady/average" [3 - 4 miles per hour], "fast" [>4 miles per hour], or "prefer not to answer" [regarded as missing data]). Participants who reported that they were unable to walk or walked at a slow pace had low physical performance.

Cognitive function was assessed through 2 neuropsychological tests, namely fluid intelligence and prospective memory, by using a touch screen during visits to the UK Biobank assessment center. The fluid intelligence test was designed as a 13-item problem-solving task aiming at logic and reasoning abilities. Prospective memory, which is a form of episodic memory, was used as an indicator to measure the participants' capacity to remember future tasks. The participants were instructed to reproduce a figure on a touch screen following a single instruction to be recalled later in the session. The responses were judged as either "correct on the first attempt" or otherwise, indicating a lapse in prospective memory (eg, "instruction not remembered, either skipped or incorrect" or "correctly recalled on the second attempt").

Covariate Measurements

The selection of potential confounders was based on previous literature [12,13], which was assessed through a touch-screen questionnaire at baseline. These variables included: age (continuous), sex (male or female), education level (college or university; A levels (Advanced Level), AS level (Advanced Subsidiary Level) or equivalent; O level, GCSEs (General Certificate of Secondary Education) or equivalent; CSEs or equivalent; NVQ (National Vocational Qualification), HND (Higher National Diploma), HNC (Higher National Certificate) or equivalent; other professional qualifications), self-reported race (White, Asian, Black, Mixed or other), assessment center, Townsend Deprivation Index at recruitment (continuous), BMI (continuous), presence of long-standing illness (no or yes), overall health rating (excellent, good, fair or poor), smoking status (never, former, or current), frequency of alcohol intake (daily or almost daily; 3 or 4 times a week; once or twice a week; 1 to 3 times a month or special occasions only), sleep duration (<7 h/day, 7 - 9 h/day, or >9 h/day), and TV viewing duration (continuous). Specifically, the presence of long-standing illness was assessed using the following question, "Do you have any long-standing illness, disability, or infirmity". Overall health rating was collected by asking "In general how would you rate your overall health?" All categorical variables strictly adhered to UK Biobank classification standards, with no additional category merging or processing.

Statistical Analyses

To address the repeated measurements of the 2 cognitive tests, we used mixed-effects linear and logistic regression models to evaluate the associations of sarcopenia and its indices with fluid intelligence scores and with the risk of prospective memory impairment, respectively. All the mixed-effects models featured a random individual-specific intercept with a fixed slope. In regression models, we adjusted for sociodemographic, socioeconomic factors, and the number of cognitive assessments, and then further added health-related factors, including BMI, long-standing illness, and health rating. Finally, lifestyle factors, including smoking, alcohol intake frequency, sleep duration, and duration of TV viewing were added. We used a missing indicator approach in the primary analysis and conducted a sensitivity analysis by excluding missing data to evaluate its impact.

MR Analyses

Data Source of Sarcopenic Indices and General Cognitive Function

Given the lack of genome-wide association studies (GWASs) specifically focused on sarcopenia, we used the publicly available summary data on sarcopenic indices and cognitive function from the UK Biobank [24,25] and the COGENT Consortium [26]. The GWAS summary data for ALM (n=450,243), handgrip strength (n=461,089), and gait speed (n=461,089) were derived from the largest public GWASs of individuals with European ancestry in the UK Biobank [24,25]. The summary genetic statistics for the associations of general cognitive function were extracted from a comprehensive GWAS conducted through the UK Biobank and COGENT Consortium [26]. The summary phenotype source and outcome descriptions are provided in Table S1 in Multimedia Appendix 1.

Genetic Instruments for Sarcopenic Indices

The single nucleotide polymorphism (SNPs) meeting the following criteria were selected as instrumental variables: (1) significantly associated with ALM, handgrip strength, or usual gait speed ($P<5\times10^{-8}$), (2) independent (linkage disequilibrium $r^2<.001$ within 10,000 kb), (3) with appropriate effect allele frequencies (≥1%), and (4) not palindromic (adenine/thymine or cytosine/guanine). To correct for multiple comparisons (3 exposures), the Bonferroni method was used. Associations with $P<.016$ (0.05/3) were deemed statistically significant.

Data Analyses

The 2-Sample MR Analyses

The associations between genetically predicted sarcopenic indices and general cognitive function were examined by multiplicative random-effects inverse variance weighted (IVW) analysis, which can provide the most accurate and unbiased estimates [27]. Furthermore, we performed MR-Egger method, MR-PRESSO method, and RadialMR method to pinpoint potential violations of MR assumptions and assess the robustness of primary results [27,28]. The RadialMR method identifies outliers influencing MR analysis, and the results are reanalyzed after their removal [29]. A consistent estimate across multiple sensitivity analyses indicates strengthened causal evidence. We also assessed the bias and type 1 error rate for sample overlap using an internet-based calculator [30]. In addition, we reanalyzed the data using the MRlap method, which is robust to biases caused by sample overlap, winner's curse, and weak instruments [31].

Mediation MR Analyses

We performed univariable MR to estimate the effects of sarcopenic indices on 11 genetically predicted putative

mediators, ie, omega-3 fatty acids, vitamin D levels, moderate-to-vigorous intensity physical activity (MVPA) during leisure time, falls, frailty, sleep disorders, anxiety, depression, stroke, metabolic syndrome, and type 2 diabetes. Mediators showing causal evidence were selected for multivariable Mendelian randomization (MVMR) analysis to estimate the indirect effect of sarcopenic indices on cognitive function mediated by each. The mediation proportion was calculated as the indirect effect divided by the total effect on cognitive function, with standard errors estimated by the delta method [32]. If an inconsistent mediation was observed, where the direct effect opposes the indirect effect, no mediation proportion would be estimated [33].

Complementary Analyses

We performed bidirectional MR analysis to partially explore the potential reverse causality. The SNPs from GWAS that were significantly associated with general cognitive function ($P<5\times10^{-8}$) were selected as instrumental variables (selection criteria remained consistent with the ones mentioned earlier). In addition, we used the MR-Steiger method to examine the directionality of the relationship [34].

All analyses were conducted using the R (R Foundation for Statistical Computing) packages *TwoSampleMR* (version 0.5.6), *MVMR* (version 0.3), *MRPRESSO* (version 1.0), and *MRlap* (version 0.0.3.0) in R (version 4.3.0). A P value <.05 was considered significant. IVW estimates were deemed causal if consistent with at least one sensitivity analysis and showed no pleiotropy (Egger intercept P>.05). Results were reported as odds ratios (ORs), β coefficients, or proportions with 95% confidence intervals (CIs).

Ethical Considerations

This study had been granted with the UK Biobank research approval by the North West Centre for Research Ethics Committee (11/NW/0382) and informed consent was obtained from all participants. For GWAS datasets, ethical review and approval can be accessed in the original studies. The data used were anonymized to ensure privacy and confidentiality. No compensation was provided to participants.

Results

Figure 1 provides an overview of the study design. The baseline characteristics of the cohort study are summarized in Table 1. Among 34,457 participants, 17,620 (51.1%) were women, with a mean age of 56.4 (SD 7.6) years.

Figure 1. Study design flowchart. ALM: appendicular lean mass; MR: Mendelian randomization.

Cohort Study

As shown in Table 2, participants with sarcopenia had lower fluid intelligence scores than those without sarcopenia, and the multivariable-adjusted difference in the mean level of fluid intelligence scores was 0.91 (95% CI −1.68 to −0.15; *P*=.02). However, no statistically significant association with prospective memory loss was detected (OR 1.36, 95% CI 0.31-5.92; *P*=.68). Each 5-kg increase in ALM was found to be associated with an increased fluid intelligence score (β=0.27, 95% CI 0.21-0.32; *P*<.001) and a decreased risk of prospective memory loss (OR 0.87, 95% CI 0.78-0.97; *P*<.001). Likewise, each 5-kg increase in handgrip strength was positively associated with fluid intelligence (β=0.02, 95% CI 0.01-0.04; *P*<.001) and negatively associated with the prospective memory loss (OR 0.89, 95% CI 0.86-0.93; *P*<.001). Furthermore, slow gait speed was associated with a lower fluid intelligence score (β=−0.10, 95% CI −0.23 to 0.03; *P*=.15) and an increased risk of prospective memory loss (OR 1.65, 95% CI 1.23-2.19; *P*<.001). The results of sensitivity analyses, after excluding cases with missing data, were consistent with the overall analyses (see Table S2 in Multimedia Appendix 1).

Table . The associations of baseline sarcopenia and its indices with follow-up cognitive function.

Sarcopenia indices	Cognitive function	
	Fluid intelligence, β (95% CI)	Prospective memory loss, OR[a] (95% CI)
Sarcopenia		
Model 1[b]	−0.87 (−1.62 to −0.12)[c]	1.67 (0.47-1.78)
Model 2[d]	−0.86 (−1.61 to −0.11)[c]	1.59 (0.39-6.50)
Model 3[e]	−0.91 (−1.68 to −0.15)[c]	1.36 (0.31-5.92)
Appendicular lean mass		
Model 1[b]	0.17 (0.13-0.21)[c]	0.87 (0.80-0.94)[c]
Model 2[d]	0.27 (0.22-0.32)[c]	0.82 (0.74-0.91)[c]
Model 3[e]	0.27 (0.21-0.32)[c]	0.87 (0.78-0.97)[c]
Handgrip strength		
Model 1[b]	0.03 (0.02-0.05)[c]	0.93 (0.89-0.96)[c]
Model 2[d]	0.03 (0.01-0.04)[c]	0.91 (0.88-0.94)[c]
Model 3[e]	0.02 (0.01-0.04)[c]	0.89 (0.86-0.93)[c]
Slow gait speed		
Model 1[b]	−0.20 (−0.32 to −0.08)[c]	1.64 (1.27-2.12)[c]
Model 2[d]	−0.14 (−0.27 to −0.01)[c]	1.71 (1.30-2.25)[c]
Model 3[e]	−0.10 (−0.23 to 0.03)	1.65 (1.23-2.19)[c]

[a]OR: odds ratio.

[b]Model 1 was adjusted for age, sex, race, aged race, education, deprivation index, and the number of cognitive assessments.

[c]*P*<.05.

[d]Model 2 was additionally adjusted for health-related factors including BMI and long-standing illness.

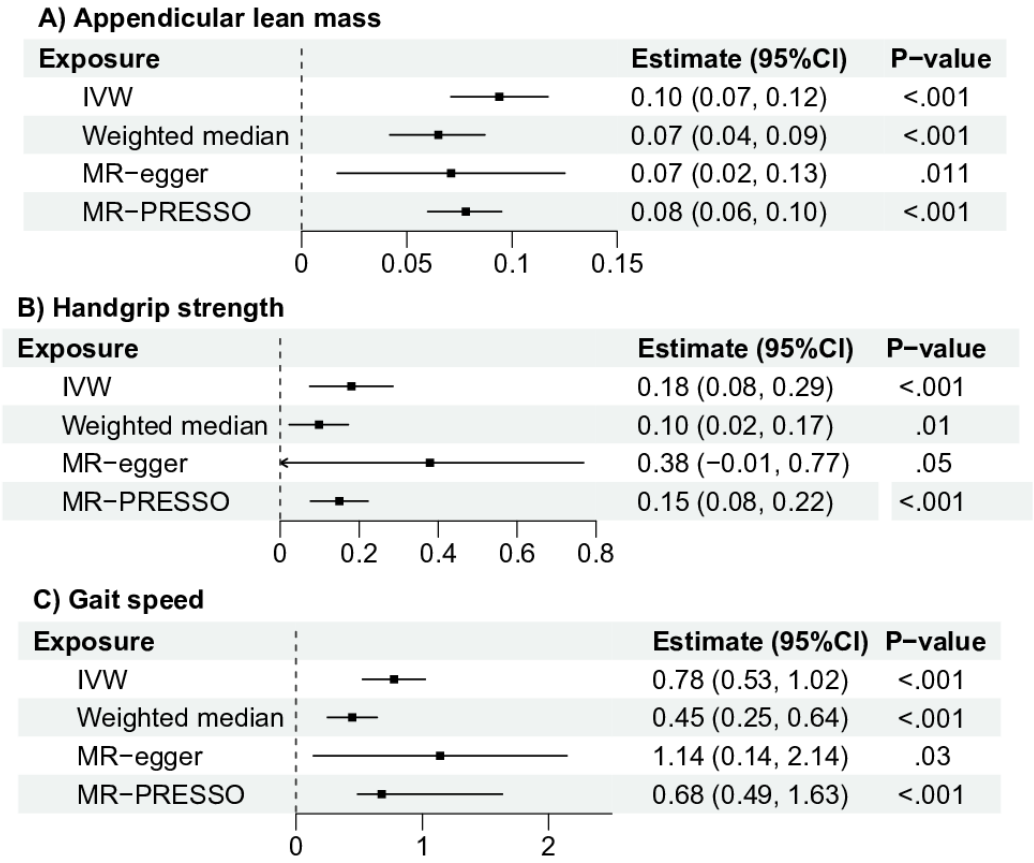
[e]Model 3 was additionally adjusted for smoking, alcohol intake, sleep duration, and TV viewing.

MR Analyses

The 2-Sample MR Analyses

As shown in Figure 2, for an increase of each one unit in genetically predicted ALM, handgrip strength, and gait speed, the general cognitive function score was increased by 0.10 (95% CI 0.07-0.12; *P*<.001), 0.18 (95% CI 0.08-0.29; *P*<.001), and 0.78 (95% CI 0.53-1.02; *P*<.001), respectively. To assess the consistency of directional causation, the effect estimates of 3 different sensitivity methods, that is, weighted median, MR-Egger, and MR-PRESSO were examined and plotted, confirming the directional causation between sarcopenic indices to general cognitive function (see Figure 2 and Figure S2 in Multimedia Appendix 1). There was some evidence of heterogeneity in the SNP effects although the MR-Egger intercepts indicated limited evidence of directional pleiotropy (see Table S3 in Multimedia Appendix 1). In radialMR analyses, outliers were detected (see Figure S3 in Multimedia Appendix 1). MR results remained consistent, showing slightly smaller effects after removing outliers (see Table S4 in Multimedia Appendix 1). For all sarcopenic indices and cognitive function phenotypes, the type 1 error rate was robustly controlled below 0.05 and bias estimates were confined to a narrow range of −0.01 to 0.01 (see Table S5 in Multimedia Appendix 1). Validation through the MRlap method further confirmed that sample overlap did not substantially influence the causal inferences (see Table S6 in Multimedia Appendix 1).

Figure 2. Mendelian randomization results for the relationship of sarcopenic indices with cognitive function. IVW: inverse variance weighted analysis; MR: Mendelian randomization.



Mediation MR Analyses

Figure 3 illustrates the effects of sarcopenic indices on 11 potential mediators. Univariable IVW MR analysis revealed that genetically predicted ALM exhibited protective effects on MVPA (β=0.07, 95% CI 0.05-0.09; *P*<.001) and negative associations with omega-3 fatty acids (β=−0.08, 95% CI −0.12 to −0.05; *P*<.001), falls (β=−0.03, 95% CI −0.05 to -0.003; *P*=.03), and frailty (β=−0.05, 95% CI −0.07 to −0.03; *P*<.001). Genetically predicted handgrip strength showed a positive association with MVPA (β=0.10, 95% CI 0.02-0.19; *P*=.02) and negative associations with falls (β=−0.15, 95% CI −0.24 to −0.07; *P*<.001), and frailty (β=−0.22, 95% CI −0.30 to −0.14; *P*<.001), depression (β=−0.09, 95% CI −0.16 to −0.01; *P*=.02), and stroke (β=−0.41, 95% CI −0.69 to −0.14; *P*=.003). Genetically predicted gait speed was positively associated with MVPA (β=0.83, 95% CI 0.65-1.01; *P*<.001). It also demonstrated significant protective effects against sleep disorders, falls, frailty, anxiety, depression, metabolic syndrome, and type 2 diabetes (with βs ranging from −0.01 to −2.32, all *P* values <.05). Further mediation analysis revealed that the total effect of genetically predicted ALM on general cognitive function decreased from 0.10 (95% CI 0.07-0.12) to 0.09 (95% CI 0.06-0.11) after adjusting for MVPA in MVMR analysis (Table 3). Similarly, the total effect of genetically predicted handgrip strength on general cognitive function attenuated from 0.18 (95% CI 0.08-0.29) to 0.16 (95% CI 0.05-0.27) with adjustment in MVMR analysis. MVPA mediated 8.2% of the total direct effect of ALM on cognitive function, and 10.6% of the total direct effect of handgrip strength on cognitive function. No apparent mediation effect was observed through omega-3 fatty acids, vitamin D level, falls, frailty, sleep disorders, anxiety, depression, stroke, metabolic syndrome, or type 2 diabetes. The type 1 error rate due to sample overlap between sarcopenic indices and the mediators remained below 0.05 (with bias estimates under 0.01) for all phenotypes (see Table S5 in Multimedia Appendix 1).

Figure 3. Effects of genetically predicted sarcopenic indices on potential mediators. MVPA: moderate-to-vigorous intensity physical activity.

Table . The mediation effect of sarcopenic indices on cognitive function via potential mediator in Mendelian randomization (MR) analyses.

Exposures	Mediator	Total effects, β (95% CI)	Direct effects, β (95% CI)	Indirect effects, β (95% CI)	Mediated proportion, % (95% CI)
Appendicular lean mass	MVPA[a]	0.10 (0.07-0.12)[b]	0.09 (0.06-0.11)[b]	0.01 (0.00-0.02)[b]	8.2 (0-16.7)
Handgrip strength	MVPA[a]	0.18 (0.08-0.29)[b]	0.16 (0.05-0.27)[b]	0.02 (0.00-0.05)[b]	10.6 (0-29.6)

[a]MVPA: moderate-to-vigorous intensity physical activity during leisure time.

[b]$P<.05$.

Complementary Analyses

We conducted bidirectional MR analysis to investigate the potential reverse causality between sarcopenia and cognitive function. Table S7 in Multimedia Appendix 1 shows evidence supporting a causal effect of genetically predicted cognitive function on all sarcopenic indices. The effect estimates demonstrated a general consistency across different sensitivity methods (see Figure S2 in Multimedia Appendix 1). Some heterogeneity in the SNP effects was observed, although the MR-Egger intercepts suggested no evidence of directional pleiotropy (see Table S7 in Multimedia Appendix 1). In radialMR analyses, outliers were detected (see Figure S4 in Multimedia Appendix 1). The MR results remained consistent both before and after outlier correction and are presented in Tables S7 and S8 in Multimedia Appendix 1.

Discussion

Principal Findings

This study revealed that sarcopenia and its defining indices (appendicular lean mass, handgrip strength, and gait speed) are associated with cognitive function based on observational data. MR analyses further established a causal relationship between higher levels of sarcopenic indices and better general cognitive function. In addition, physical activity was identified as a significant mediator in the causal pathway linking sarcopenic indices to cognitive function. Our findings suggest sarcopenia as a risk factor and potential biomarker for cognitive impairment, with physical activity offering a therapeutic approach to delay or prevent cognitive decline.

Comparison With Previous Work

The association between sarcopenia and the risk of cognitive impairment has been investigated by several longitudinal studies, but the results were conflicting. Some authors indicated that individuals with sarcopenia [12-17], reduced muscle strength [13,17,35], decreased muscle mass [35], or compromised physical performance [35,36] were associated with an elevated risk of cognitive impairment. However, some others reported no significant association between sarcopenia or its indicators and the risk of cognitive impairment [19-21]. The conflicting results could stem from differences in how sarcopenia is defined and the variations in sample sizes. Our observational analyses addressed these discrepancies by focusing on the more recent EWGSOP2 definition of sarcopenia and its 3 defining indices within a substantial sample size (>200,000 participants). As a result, we found that sarcopenia, as a construct, and its 3 distinct indices were closely correlated with cognitive impairment. Furthermore, the discrepancies observed in previous observational studies might also be attributed to factors such as residual confounding and measurement errors. To mitigate these limitations in our study, we used MR, a genetic epidemiological technique using genetic variants as proxies for the exposure [37]. This approach is less vulnerable to the aforementioned limitations since the genetic variants are accurately measured and documented and are randomly allocated during gamete formation and conception. Therefore, this method can minimize the potential for measurement errors and reduce the likelihood of being influenced by confounding variables [37].

Possible Explanations

Our study demonstrates that physical inactivity is a potential mediating factor in the causal pathway between sarcopenia and cognitive impairment. On one hand, individuals with sarcopenia might have a low level of physical activity [38], which could be attributed to the fact that weakened muscles might hinder the ability to exercise regularly. On the other hand, physical activity positively impacts brain health [39]. First, it can stimulate the formation of new neurons, enhance neuronal survival [10], increase resistance to brain injuries, and facilitate synaptic development and plasticity [40]. Second, physical activity promotes better blood vessel formation in the brain, which is associated with increased learning capabilities [10,11]. Third, it also activates specific gene expression profiles benefiting brain plasticity and cognitive function [41]. Fourth, engaging in physical activity has been associated with reduced amyloid deposition in the brains of cognitively normal elderly adults [42]. Furthermore, physical activity can reduce systemic inflammatory markers [43] and boost the production of neuroprotective proteins like brain-derived neurotrophic factor (BDNF), supporting the growth and survival of neurons [44]. In addition, it positively influences energy balance and glucose metabolism by modulating AMP kinase and insulin signaling, potentially aiding Aβ clearance [45]. These multiple benefits of physical activity contribute to safeguarding cognitive function and underscore the importance of maintaining an active lifestyle in individuals with sarcopenia to support brain health.

Limitations

The triangulation of findings through complementary cohort and MR approaches significantly bolstered the confidence in our drawn inferences. However, several limitations warrant consideration. First, despite using multiple MR methods to resist pleiotropy-related confounding, we could not eliminate residual confounding, which is a known limitation of the MR approach. Second, due to a mere 5% response rate and healthy volunteer bias in the UK Biobank, whether our findings can be generalized

to the broader UK population remains uncertain, despite the large sample size. Third, although we have accounted for common modifiable lifestyle factors and preventable diseases to inform public health policies, this study does not encompass all potential mediation pathways. Fourth, only self-reported gait speed was collected, lacking objective measurements for more accurate estimates. Fifth, the inability to perform stratified analyses by age and gender due to data constraints limits insights into these factors' roles in the sarcopenia-cognition relationship. Sixth, the overlap between GWAS datasets in the MR analysis could bias results and inflate Type 1 error rates. To address this, we assessed the error rate and applied the MRlap method, confirming the robustness of our findings and minimizing the influence of sample overlap on causal associations. Finally, to maintain homogeneity, we focused on individuals of European ancestry in our sample selection, which might influence the generalization of the results, although the sample size was substantial.

Clinical and Research Implications

Our findings provide a promising approach to alleviate the burden of cognitive impairment by identifying and intervening in sarcopenia. Specifically, we have recognized sarcopenia as a risk factor for future cognitive impairment, making it a potential clinical biomarker to screen adults at risk of late-life cognitive impairment. Although no pharmaceutical treatment has been specifically approved for sarcopenia, implementing non-pharmacological interventions, such as physical activity, can serve as a therapeutic approach to proactively delay or prevent the onset of cognitive impairment in affected individuals. Our research indicates that physical activity can mediate the effect of sarcopenia on cognitive function, offering valuable insights that complement the prevailing emphasis on intellectual pursuits as the primary means of exercising the brain [46]. Promoting physical activity may yield a dual positive impact, addressing both sarcopenia and cognitive impairment simultaneously. This approach can potentially enhance the overall health and well-being of those affected by sarcopenia.

Conclusions

Our study suggests that sarcopenia is a causal risk factor for cognitive impairment. Physical activity, a modifiable factor, is capable of measuring the effect of sarcopenia on cognitive function.

Abstract

Background: The US population is aging. With this demographic shift, more older adults will be living with chronic conditions and geriatric syndromes. To prepare the next generation of health care professionals for this aging population, we need to provide training that captures the complexity of geriatric care.

Objective: This pilot study aimed to assess the feasibility of the cinematic–virtual reality (cine-VR) training in the complexity of geriatric care. We measured changes in attitudes to disability, self-efficacy to identify and manage elder abuse and neglect, and empathy before and after participating in the training program.

Methods: We conducted a single-arm, pretest-posttest pilot study to assess the feasibility of a cine-VR training and measure changes in attitudes to disability, self-efficacy to identify and manage elder abuse and neglect, and empathy. Health professional students from a large university in the Midwest were invited to participate in 1 of 4 cine-VR trainings. Participants completed 3 surveys before and after the cine-VR training. We performed paired *t* tests to examine changes in these constructs before and after the training.

Results: A total of 65 health professional students participated in and completed the full cine-VR training for 100% retention. Participants did not report any technological difficulties or adverse effects from wearing the head-mounted displays or viewing the 360-degree video. Out of the 65 participants, 48 completed the pre- and postassessments. We observed an increase in awareness of discrimination towards people with disability (t_{47}=−3.97; P<.001). In addition, we observed significant improvements in self-efficacy to identify and manage elder abuse and neglect (t_{47}=−3.36; P=.002). Finally, we observed an increase in participants' empathy (t_{47}=−2.33; P=.02).

Conclusions: We demonstrated that our cine-VR training program was feasible and acceptable to health professional students at our Midwestern university. Findings suggest that the cine-VR training increased awareness of discrimination towards people with disabilities, improved self-efficacy to identify and manage elder abuse and neglect, and increased empathy. Future research using a randomized controlled trial design with a larger, more diverse sample and a proper control condition is needed to confirm the effectiveness of our cine-VR training.

Introduction

The US population is aging. Over the next 3 decades, the number of Americans aged 65 and older is projected to increase from 58 million in 2022 to 82 million in 2050, representing a 47% increase [1]. With this demographic shift, more older adults will be living with chronic conditions. According to the National Council on Aging, 94.9% of adults aged 60 years and older have at least one chronic condition and 78.7% have two or more [2]. Furthermore, 42% of adults aged 60 years and older have

obesity, which increases the risk for cardiovascular disease, type 2 diabetes, and certain cancers [3]. This translates to older Americans requiring more health care and access to health care professionals. Thus, training the next generation of health care professionals in the complexity of care for older adults is an urgent need.

Despite this need, the education system lacks adequate training in geriatric care [4]. Health professional training should address age-related physiological, physical, cognitive, and psychosocial changes that may negatively impact quality of life, disability, morbidity, and mortality [5,6]. Furthermore, this training should emphasize the early detection of and treatment for geriatric syndromes (eg, polypharmacy, falls, frailty, and incontinence) given their high prevalence and frequent under-recognition in older adults [7]. Finally, health professional training should draw attention to implicit and explicit biases in aging as well as ethical issues related to elder abuse and neglect and end-of-life care [8].

Clinical simulation may be an innovative approach to teaching health professional students about the complexity of care in older adults. Previous research demonstrates that clinical simulation is an effective methodology for health professional students [9]. The value of clinical simulation is that it replaces or enhances real experiences with guided experiences that replicate the real world in a fully interactive manner [10]. Furthermore, clinical simulation is repeatable, which allows for the repetition of acquired skills with appropriate feedback [11]. Clinical simulation can be delivered in different modalities, including role play, the use of standardized patients, computer screen-based simulation, and the use of electronic patient records [11]. Electronic patients are most commonly mannequin-based or replicas of clinical sites; however, new advancements in technology have led to more sophisticated and realistic virtual reality (VR) based simulations [12].

Cinematic-VR (cine-VR) is one type of VR-based simulation. Specifically, cine-VR leverages 360-degree video and spatialized audio through film. It differs from traditional VR, which uses computer-generated characters and worlds. In cine-VR, filmmakers apply the techniques of cinema (ie, narrative storytelling, script writing, actors, lighting, and postproduction) to create an immersive, visually compelling environment [13,14]. We created a cine-VR training program to depict the complexity of geriatric care. Our clinical simulation depicted an older adult with multimorbidity, disability, and several geriatric syndromes. In addition, we wove in themes of intersectionality with regards to ageism, ableism, and racism. We conducted a pilot study to assess the feasibility and acceptability of the cine-VR training program with health professional students. We also measured changes in health professional students' attitudes toward disability, self-efficacy to identify and manage elder abuse and neglect, and empathy. The pilot study was designed to assess the feasibility of our data collection methods, willingness of participants to complete the cine-VR training program, sample size estimation, and refinement of measurements. We will use the findings to inform the development of a future randomized controlled trial to compare the cine-VR training program to traditional instruction.

Methods

Research Design

We conducted a single-arm, pretest-posttest study to assess changes in attitudes to disability, self-efficacy to identify and manage elder abuse and neglect, and empathy.

Ethical Considerations

We obtained ethics approval from the Ohio University Office of Research Compliance Institutional Review Board (approval number: #22-X-153). We ensured our pilot study met the requirements set forth in the regulations on public welfare in Part 46 of Title 45 of the Code of Federal Regulations (45 CFR 46) by complying with federal, state, and local laws and regulations for human subjects; the principles set forth in "The Belmont Report," and the Helsinki Declaration of 1975. All participants provided electronic informed consent. Informed consent was completed before participation in the study.

Cine-VR Episodes

The cine-VR episodes were designed to educate health professional students about complex health conditions, social drivers of health, and implicit bias. We conveyed these objectives through our patient, John Chen, an 80-year-old Chinese American man with a 14-year history of type 2 diabetes and comorbid hypertension. Mr. Chen is a person who is hard of hearing with a mobility disability. His most recent HBA_{1c} level was 9.7%. His medications include metformin and glyburide for his diabetes and lisinopril for his blood pressure. He also has osteoarthritis, decreased renal function (eGFR=58 mL/min/1.73 m^2), elevated triglycerides due to his glucose levels (299 mg/dL), and a body mass index of 23.1 kg/m^2. He has not received diabetes self-management education and support, despite being enrolled in both Medicare and Medicaid. Recently, Mr Chen moved in with his son's family, but he is having a difficult time adjusting to his new home. Although he is able to move around on his own, his ambulation is unsteady, and he falls often. He also experiences frequent urinary incontinence, which frustrates his son and daughter-in-law because they have to clean him. Furthermore, Mr Chen does not drive, shop, cook, or bathe on his own. Therefore, he is reliant on his family to meet most of his daily needs. This leaves Mr Chen feeling isolated, dependent, and ashamed of his physical limitations.

In the cine-VR training program, participants watched 6 episodes, ranging in length from 2 minutes to 5 minutes. The episodes captured 3 separate patient-provider interactions, including visits with a primary care physician, an urgent care physician, and an emergency department physician. Participants were encouraged to identify issues with his medical care as well as concerns about the caregiving he received at home. Specifically, participants were challenged to figure out why Mr Chen was experiencing so many falls, injuries, and health emergencies.

The fifth and sixth episodes of the cine-VR training program were "guided simulations," or prerecorded cine-VR face-to-face conversations with the emergency department physician and Mr Chen. The guided simulations were designed to simulate a

high-stakes conversation, to give participants an opportunity to practice difficult conversations without the pressure of causing harm. Participants were instructed to speak predetermined dialogue that appeared at the bottom of the 360-degree video visible within the headset. The first "guided simulation" was a conversation between the participant and the emergency department physician. The participant assumed the role of a clinical colleague and encouraged the physician to inquire further about the bruises observed on John's body and to call social work for suspicion of elder abuse and neglect. The second "guided simulation" was a conversation between the emergency department physician, Mr Chen, and a social worker. In this "guided simulation," the participant took on the role of the emergency department physician and asked Mr Chen difficult questions about his injuries, his family, and life at home.

Cine-VR Training Curricular Content

We developed curricular content to be taught in tandem with the cine-VR episodes. The curriculum included 6 debriefs or reflections that reinforced key takeaways from each cine-VR episode. The key takeaways from each episode focused on the following content: (1) Diabetes, disability, and the aging population, (2) bias toward disability, (3) association between disability and elder abuse and neglect, (4) recognizing elder abuse and neglect, (5) identifying risk factors for elder abuse and neglect, and (6) reporting elder abuse and neglect. An experienced behavioral diabetes researcher (EAB) delivered both trainings. The integrity of the curricular content was ensured by written materials, a peer-review process of all materials, delivery by one trained behavioral diabetes expert, and team member observation of cine-VR training.

Cine-VR Technology

Participants viewed the cine-VR episodes with Pico G2 4K head-mounted displays. These head-mounted displays allowed participants to move their head and body in any direction to choose what aspects they paid attention to during each cine-VR episode. We also synchronized all cine-VR episodes from a central computer using VR Sync software so all participants viewed the same content in the head-mounted display at the same time.

Power Analysis

This was a pilot study so we did not conduct an a priori power analysis. Using the guidance of Lancaster et al [15], we recruited a minimum sample size of 30 participants.

Recruitment

Health professional students were recruited from a large university in the Midwest. Eligibility criteria for participating in the pilot study included English-speaking and reading adults aged 18 years and older who were enrolled during the 2022 - 2023 academic year and majoring in one of the following programs: premedicine program, speech-language pathology, audiology, nutrition and dietetics, physical therapy, nursing (any level), social work (any level), athletic training, exercise physiology, pre-physician assistant program, psychology, public health administration, or public health. There were no other exclusion criteria. Specifically, we hosted 4 in-person cine-VR training sessions on campus in classrooms and invited students from those health professional programs to participate. Sessions were hosted on October 17, 2022, October 24, 2022, April 5, 2023, and June 6, 2023.

Measures

To assess the feasibility of the cine-VR training program, we measured recruitment, retention, length of time required to recruit, rate of completion of the cine-VR training, and feasibility of the data collection measures. In addition, participants provided demographic factors (age, gender, race, ethnicity, year in program, and program) and completed the following measures:

Attitudes to Disability Scale

The Attitudes to Disability Scale [16] is a 16-item validated scale that assesses attitudes toward disability and attitudes toward people with a disability. The 16 items were answered on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). The scale included 4 domains or subscales with good internal consistency: Inclusion—focuses on attitudes toward the inclusion and exclusion for people with disabilities as well as the burden on families and society (Cronbach α=0.76), Discrimination—focuses on awareness of unfair and prejudicial treatment to people with disabilities (Cronbach α=0.74), Gains—focuses on positives of having a disability (Cronbach α=0.75), and Prospects—focuses on future hopes and whether disability impacts those hopes (Cronbach α=0.72) [16].

Responding to Elder Abuse in GERiAtric Care—Provider Questionnaire

The Responding to Elder Abuse in GERiAtric Care—Provider Questionnaire [17] is a validated 25-item scale that assesses health care provider preparedness to identify and manage elder abuse and neglect. For the purposes of this study, we used 8 of the 25 items. The items we used addressed self-efficacy to identify and manage elder abuse and neglect on a 0 to 10 scale. The 17 excluded items were written for practicing health care professionals. In our sample, the 8 self-efficacy questions demonstrated excellent internal consistency for identifying and managing elder abuse and neglect (Cronbach α=0.95) [17].

Jefferson Scale of Empathy Health Professionals Students Version

The Jefferson Scale of Empathy Health Professionals Students Version [18] is a 20-item validated scale that assesses empathy among health professional students. The 20 items were answered on a 7-point Likert scale, ranging from 1 (strongly disagree) to 7 (strongly agree). Scores are summed for a composite score, ranging from 20 to 140. The scale demonstrated good internal consistency (Cronbach α=0.85) [18].

Data Collection

Participants completed the assessments through Qualtrics, an electronic questionnaire service. To access the preassessment, participants scanned a QR code from a Microsoft PowerPoint slide that directed them to the Qualtrics website. The Qualtrics website included a brief description of the study, the informed consent form, demographic questions, and the 3 measures. All participants provided informed consent without a signature in Qualtrics before completing the measures. After the cine-VR

training, participants scanned a different QR code that directed them to the postassessment measures.

We collected data anonymously. To link participants' pre- and postassessment responses, we included 3 questions at the beginning of the pre- and postassessments, which served as a unique identifier (ie, model of first car, high school mascot, and the day of the month on which they were born [eg, 31]). Total time to complete the pre- and postmeasures took approximately 15 - 20 minutes. Participants received a US $25 gift card for human subject compensation. To maintain anonymity, participants clicked on a new Qualtrics link that was not connected to their pre- or postmeasures to receive a gift card; it was possible that participants received compensation without completing all pre- and postmeasures.

Statistical Analysis

First, we assessed participants' demographic factors using descriptive statistics and presented them as means and SDs or sample size and percentages. Next, we examined the distribution of the data to ensure they met statistical test assumptions. To assess changes pre- and post–cine-VR training, we conducted paired *t* tests; all test statistics are presented with α values and degrees of freedom. We also calculated effect sizes using Cohen *d*, with a small effect=0.2, medium effect=0.5, and a large effect=0.8. We defined statistical significance as a *P* value less than .05 and conducted analyses in IBM SPSS statistical software (version 29.0).

Results

Feasibility

A total of 65 health professional students participated in and completed the full cine-VR training for 100% retention. Participants did not report any technological difficulties or adverse effects from wearing the head-mounted displays or viewing the 360-degree video. We scheduled 4 cine-VR trainings in a 6-month period to recruit the 65 participants, and all 4 trainings lasted approximately 60 minutes. For data collection, 65 participants completed the preassessment measures; however, only 48 completed the postassessment measures, resulting in a 74% completion rate. The 74% rate of completion suggests that we may want to consider adaptations or refinements to our selected measures. Overall, the ease of recruitment, length of time required to recruit, retention in the cine-VR trainings, and feasibility of data collection methods suggest that the cine-VR training was feasible.

Demographics

A total of 48 health professional students consented to participate in the pilot study and completed all pre- and postassessments. The mean age of participants was 22.5 (SD 3) (see Table 1). A total of 41 participants (85.4%) self-identified as women, 6 (12.5%) self-identified as men, and 1 (2.1%) self-identified as nonbinary. The participants self-identified their race as follows: 6.3% (3/48) Asian or Pacific Islander, 18.8% (9/48) Black or African American, 4.2% (2/48) Mixed Race, and 70.8% (34/48) White. For ethnicity, 2 participants (4.2%) self-identified as Hispanic, Latino, or Spanish origin and 2 (4.2%) self-identified as Mexican, Mexican American, or Chicano. The majority of participants were in the final year of their program (37.5%, 18/48), with premedicine as the most reported major (42.6%, 20/48).

Table . Participant demographic characteristics in the cinematic-virtual reality (cine-VR) study (N=48).

Attitudes Toward Disability Findings

Pre- and postdomain scores for the Attitudes to Disability Scale can be found in Table 2. Post–cine-VR training, we observed significant changes in 1 of the 4 Attitudes to Disability Subscales: Discrimination Domain (t_{47}=−3.97, P<.001). This change had a Cohen d=0.55, indicating a medium effect. This finding suggests that the cine-VR training may have increased participants’ awareness of discrimination towards people with a disability. In the Discrimination Domain, 3 of the 4 items showed a significant change with more participants “agreeing” and “strongly agreeing” with the following statements posttraining: “People often make fun of disabilities” (t_{47}=−3.92; P<.001); “People tend to become impatient with those with a disability” (t_{47}=−3.19; P=.003); and “People tend to treat those with a disability as if they have no feelings” (t_{47}=−2.69; P=.01). Post-cine-VR training, we did not observe significant changes in the Inclusion Domain (t_{47}=−.16; P=.88), Gains Domain (t_{47}=−1.76; P=.08), or Prospects Domain (t_{47}=−.30; P=.77).

Table . Participants' attitudes to disability scale mean scores before and after the cinematic-virtual reality (cine-VR) training program (N=48).

Questions	Pre-VR[a], mean (SD)	Post-VR, mean (SD)	*t* test (*df*)	*P* value

Self-Efficacy to Identify and Manage Elder Abuse and Neglect Findings

Post—cine-VR training, we observed significant changes in participants' self-efficacy to identify and manage elder abuse and neglect (t_{47}=−3.36, *P*=.002, Table 3). This change had a Cohen *d*=0.49, approaching a medium effect.

Table . Participants' perceived self-efficacy for identifying and managing elder abuse and neglect before and after the cinematic-virtual reality (cine-VR) training program (N=48).

Questions	Pre-VR,[a] mean (SD)	Post-VR, mean (SD)	*t* test (*df*)	*P* value	Cohen *d*
Asking questions about abuse to an older patient who has clear indications of now being, or having previously been, subjected to abuse.	6.2 (2.4)	7.2 (2.4)	−3.354 (47)	.002	.48
Asking questions about abuse to an older patient who has no clear indications of now being or having previously been, subjected to abuse.	5.7 (2.6)	5.9 (2.4)	−.585 (47)	.56	.08
Ensuring you are able to ask questions about abuse in private to an older patient who has a relative who insists on being present during all contact.	6.1 (2.7)	7.0 (2.4)	−2.911 (47)	.005	.42
In conversation, providing support to an older patient who tells about abuse.	7.4 (2.6)	8.0 (2.1)	−2.438 (47)	.02	.35
Helping an older patient subjected to abuse on to the right body in health care, or to the right support function in society.	6.6 (2.9)	7.7 (2.1)	−3.174 (47)	.003	.46
Helping an older patient subjected to abuse to make a report to the police or social services.	6.9 (2.8)	7.6 (2.2)	−1.984 (47)	.05	.29
Helping and supporting an older patient subjected to abuse, who does not currently want to change his or her situation.	5.5 (2.9)	6.3 (2.6)	−2.433 (47)	.02	.35
Handling the meeting with an older patient who says no to questions about abuse, but where you still have strong suspicions that the patient is subjected to abuse.	5.7 (2.8)	6.6 (2.2)	−2.601 (47)	.01	.38
Total	6.3 (2.4)	7.0 (1.8)	−3.364 (47)	.002	.49

[a]VR: virtual reality.

In total, 6 of the 8 items demonstrated significant improvements in perceived self-efficacy. Specifically, participants reported increases in their self-efficacy to ask questions about abuse to an older individual who has clear indications of being abused (t_{47}=−3.354; *P*=.002; Cohen *d*=0.48) and to ensure that they ask questions about abuse in private (t_{47}=−2.911; *P*=.005; Cohen *d*=0.42). We also observed increases in self-efficacy for providing support to an older individual who discloses abuse (t_{47}=−2.438; *P*=.02; Cohen *d*=0.35) and directing an older adult experiencing abuse to the right support person or service

(t_{47}=−3.174; P=.003; Cohen d=0.46). Finally, participants showed improvements in their self-efficacy for helping older adults experiencing abuse who do not want to change their situation (t_{47}=−2.433; P=.02; Cohen d=0.35) and handling an older person who says no to questions about abuse despite strong suspicions of abuse (t_{47}=−2.601; P=.01; Cohen d=0.38).

One item showed a trend in improving self-efficacy to help an older adult make a report to the police or social services (t_{47}=−1.984; P=.05; Cohen d=0.29). Participants did not show an improvement in their self-efficacy to ask questions about abuse to an older adult who has no clear indications of presently or previously experiencing abuse (t_{47}=−.585; P=.56; Cohen d=0.08). This finding highlights an area to be addressed in future research.

Empathy Findings

Pre–cine-VR training empathy scores ranged from 47 to 128, with a mean of 105.7 (SD 16.6). Post–cine-VR training empathy scores ranged from 80 to 131, with a mean of 110.4 (SD 12.1). We observed a significant increase in participants' empathy scores post–cine-VR training (mean change=4.8; t_{47}=−2.329; P=.02), with a Cohen d=0.34 indicating a small effect. This finding indicates a noticeable difference in empathy before and after participating in the cine-VR training. While the effect size is small, an increase in empathy may have practical significance in training health professional students about the complexity of diabetes management. More research is needed to confirm this finding.

Discussion

Principal Findings

In this pilot study, we assessed the feasibility of implementing a cine-VR training program with health professional students. Our findings showed that we were able to recruit, implement, and retain participants for the full cine-VR training. Furthermore, participants reported no adverse effects or issues with the cine-VR technology. In total, 3-quarters of the participants completed the pre- and postmeasures for the pilot study. Overall, we observed significant improvements in participants' awareness of discrimination toward people with disability, self-efficacy to identify and manage elder abuse and neglect, and empathy. These improvements suggest that the cine-VR training program may be an effective teaching modality to educate health professional students about the complexity of care in older adults. More research is needed with a larger, more diverse sample and a proper attention control condition to confirm its effectiveness.

An objective of the cine-VR training program was to raise awareness about discrimination towards aging and disabilities. The cine-VR training portrayed multiple interactions among Mr Chen, his family, and health care providers to raise awareness about discrimination. In one simulation, for instance, Mr Chen's grandson is depicted yelling "Good morning!" and laughing, a reaction to his grandfather's hearing loss. Later in the same simulation, his daughter-in-law appears visibly frustrated following an incident of urinary incontinence. These interactions were included to show that sometimes people, including family members, make fun of disabilities or become impatient with people who have a disability. Similarly, the cine-VR training included episodes involving the primary care physician and urgent care physician, directing their questions about Mr Chen's medical history to his son and daughter-in-law, rather than speaking to Mr Chen directly. This was done intentionally to suggest that the providers did not think Mr Chen was capable of discussing his own health. In addition, we included an insensitive comment from the urgent care physician directed at Mr Chen poking fun of his situation. These scenarios were designed to illustrate various types of discrimination and elicit emotional reactions from the participants. Learning that involves emotions increases memory retention through emotional engagement, enhanced cognitive processing, and memory consolidation [19,20]. The brain tends to prioritize emotionally significant information for long-term memory over neutral information, which may explain the increased awareness of discrimination observed in the findings [21].

The cine-VR training program also emphasized recognizing the signs of elder abuse and neglect, how to report abuse, and the subsequent actions taken after a report is made. Each episode uncovered new signs of elder abuse and neglect involving Mr Chen (eg, withholding fluids throughout the day to prevent urinary incontinence, not refilling Mr Chen's medications, and making Mr Chen live in the garage while the house is being renovated), alongside behaviors commonly exhibited by abusers. The follow-up debriefs and reflections concentrated on the responsibilities of mandated reporters, the reporting process, and the steps that follow a report. This content likely contributed to the participants' increased self-efficacy in asking older adults about abuse, ensuring questions asked about abuse are asked in private, providing emotional support to an older adult who tells you about abuse, helping an older adult subjected to abuse to the right authorities, helping an older adult subjected to abuse who does not want to change circumstances, and handling an older adult who denies abuse but you have strong suspicions that they are subjected to abuse. Additional research is needed to confirm if these increases in self-efficacy are sustained over time.

Comparison With Previous Work

Medical training uses a variety of simulation types to prepare health professional students for clinical practice. The most common types of simulation include manikins and advanced patient simulators, standardized patients, and task trainers [22]. The first manikin-based simulation can be traced back to the 1960s with the development of Resusci Anne for CPR training [23]. Since then, health professional students have used manikins and advanced patient simulators to replicate complex medical scenarios, including cardiac arrest, childbirth delivery, and trauma resuscitation [23]. The advantages of using manikins and advanced patient simulators include a risk-free setting for repeated practice of clinical skills and standardized training experiences [24-26]. Drawbacks of using manikins and advanced patient simulators include the high purchase price, ongoing maintenance costs, and the technological limitations that prevent them from fully replicating the complexity and unpredictability of human behavior [27,28]. Conversely, standardized patients

provide a more realistic interaction for students. Standardized patients have been shown to improve communication skills, critical thinking, self-efficacy, and clinical examination skills [29]. Despite training, standardized patients may show individual differences that can lead to variations in role portrayal, impacting the consistency of the simulated learning experience [30]. Unlike manikins, advanced patient simulators, and standardized patients, a task trainer is a specific device designed to help train health professional students on how to perform specific procedures, such as inserting an intravenous line or performing a lumbar puncture. Task trainers allow for focused learning, skill mastery, and standardization of training in a safe learning environment equipped to provide feedback and assessment; however, they are limited in scope, lack human interaction, and require regular maintenance and upkeep to remain functional [22].

Cine-VR builds on these traditional simulation methods by integrating narrative storytelling and interactive visual experiences [13,14,31,32]. Unlike manikins, advanced patient simulators, and task trainers, cine-VR offers an immersive environment that shows real-life scenarios, situational complexity, and human emotions [33]. Furthermore, cine-VR can provide both physical and decision-based feedback through interactive episodes, whereas task trainers only provide physical feedback for procedural skills. Furthermore, standardized patients offer realistic encounters with patients; however, actors can vary in their portrayal of patients, which affects the consistency of the training. Cine-VR can standardize patient interactions while also allowing for variations in patient interactions to balance consistency with the flexibility to adapt to human unpredictability. Altogether, cine-VR incorporates elements from manikins, advanced patient simulators, standardized patients, and task trainers into a single comprehensive training tool [33].

Our cine-VR training program has several advantages compared with other simulation approaches. First, our cine-VR was standardized, safe, and reusable. If needed, participants can repeat the training as often as desired to learn or reinforce knowledge and clinical skills. In addition, participants could practice difficult, high-stakes conversations through our "guided simulations," without any risk or harm to the patient, Mr Chen. Next, the multisensory experience of cine-VR engages emotional learning. Research on emotional learning shows that it increases long-term memory as well as increased acquisition of skills [34-36]. Finally, cine-VR training offers participants a glimpse into the lives of their patients, thereby increasing their awareness of another person's feelings and experiences. This form of perspective-taking increases empathy similar to the findings in our pilot study [32,37,38]. A 2017 study by Schutte and Silinovic [39] compared the impact of VR and traditional didactic learning on empathy among undergraduate students. They found participants in the VR group reported greater increases in empathy compared to the didactic presentation group. Thus, cine-VR has the potential to increase empathy in health professional students; more research is needed to assess empathy and other prosocial behaviors (ie, helping, sharing, and comforting) in future research. Considering patients value empathy from their health care professionals, often as much or even more than clinical expertise, simulation training that enhances empathy is crucial [40,41].

Limitations

Limitations of this study included the small sample, data collected from one site, heterogeneity of health care specialties, selection bias, subject bias, and lack of a control group. We recruited a sample of 65 participants for the training, and of those, 48 completed the pre- and postassessment. While the sample of 48 participants was small, it was sufficient to pilot the measures for our pilot study. Next, we collected data from one university in the Midwest, which limits the generalizability of our findings to all health professional students. Furthermore, participants represented 6 different health professional fields. Geriatric care is inherently interprofessional and typically requires collaboration from multiple health care professionals. However, the small sample size across 6 health professional programs limits the ability to draw conclusions about the cine-VR training program in these fields. In addition, students who volunteered to participate may have been more willing or motivated to participate in this cine-VR training on care for older adults. Thus, the findings may be susceptible to subject bias and social desirability bias. Finally, we did not include a control condition as a comparison group. Future research with a large sample size must include a control condition to determine the effectiveness of the cine-VR training. In future work, we plan to conduct a randomized controlled trial comparing the effectiveness of the cine-VR training to simulated patients. Simulated patients are used extensively in medical training to enhance the educational experience of health professional students; however, simulated patients can be costly and time-consuming. If we demonstrate that the cine-VR training is more effective or equally effective as simulated patients, cine-VR training may be a more sustainable, cost-effective approach to refine health professional students' clinical and communication skills without the risk of harming real patients.

Conclusions

We demonstrated that our cine-VR training program was feasible and acceptable to health professional students at our university in the Midwestern United States. Our findings suggest that the training increased awareness of discrimination towards people with disability, improved self-efficacy to identify and manage elder abuse and neglect, and increased empathy. More research is needed to confirm the effectiveness of this cine-VR training program on the complexity of care for older adults. Future research should use a randomized controlled trial to compare the cine-VR to an attention control condition, such as simulated patients. If confirmed, the cine-VR training program may be a new, effective approach to learning about multimorbidity, geriatric syndromes, and biases related to aging.

Acknowledgments

The research was funded by the Osteopathic Heritage Foundation Ralph S Licklider, DO Endowed Professor awarded to EAB. The creation of the virtual reality simulations was part of the Medicaid Care Experience Simulation funded by the Ohio Department of Medicaid and administered by the Ohio Colleges of Medicine Government Resource Center. Abstract

Background: Parkinson disease (PD) is a progressive neurodegenerative disorder characterized by motor symptoms. Recently, dance has started to be considered an effective intervention for people with PD. Several findings in the literature emphasize the necessity for deeper exploration into the synergistic impacts of dance therapy and exergaming for PD management. Moreover, socially engaging robotic platforms equipped with advanced interaction and perception features offer potential for monitoring patients' posture and enhancing workout routines with tailored cues.

Objective: This paper presents the results of the Social Robotics for Active and Healthy Ageing (SI-Robotics) project, aimed at designing an innovative rehabilitation program targeted at seniors affected by (early-stage) PD. This study therefore aims to assess the usefulness of a dance-based rehabilitation program enriched by artificial intelligence–based exergames and contextual robotic assistance in improving motor function, balance, gait, and quality of life in patients with PD. The acceptability of the system is also investigated.

Methods: The study is designed as a technical feasibility pilot to test the SI-Robotics system. For this study, 20 patients with PD were recruited. A total of 16 Irish dance–based rehabilitation sessions of 50 minutes were conducted (2 sessions per week, for 8 wks), involving 2 patients at a time. The designed rehabilitation session involves three main actors: (1) a therapist, (2) a patient, and (3) a socially interacting robot. To stimulate engagement, sessions were organized in the shape of exergames where an avatar shows patients the movements they should perform to correctly carry out a dance-based rehabilitation exercise.

Results: Statistical analysis reveals a significant difference on the Performance-Oriented Mobility Assessment scale, both on balance and gait aspects, together with improvements in Short Physical Performance Battery, Unified Parkinson Disease Rating Scale–III, and Timed Up and Go test, underlying the usefulness of the rehabilitation intervention on the motor symptoms of PD. The analysis of the Unified Theory of Acceptance and Use of Technology subscales provided valuable insights into users' perceptions and interactions with the system.

Conclusions: This research underscores the promise of merging dance therapy with interactive exergaming on a robotic platform as an innovative strategy to enhance motor function, balance, gait, and overall quality of life for patients grappling with PD.

KEYWORDS

Parkinson disease; rehabilitation; Irish dancing; balance; gait; socially interacting robot

Introduction

Parkinson disease (PD) is a progressive neurodegenerative disorder characterized by motor symptoms, such as tremors, bradykinesia, rigidity, and postural instability, as well as nonmotor symptoms, including cognitive impairment, mood disorders, and autonomic dysfunction [1]. These symptoms can significantly impact patients' quality of life and independence as the disease progresses. While pharmacological interventions, such as dopamine replacement therapy, remain the mainstay of PD management, their efficacy may diminish over time and they often fail to address the nonmotor symptoms adequately [2]. Physical therapy represents the key adjuvant treatment for PD, offering potential benefits in improving motor function, balance, gait, and overall mobility [3]. Among various forms of physical therapy, dance-based interventions have gained attention due to their multifaceted approach targeting motor, cognitive, and psychosocial aspects of the disease [4]. Dance therapy engages patients in rhythmic movements, music, and social interaction, promoting coordination, flexibility, and emotional well-being [5].

Exergaming, which involves interactive video games requiring physical movement, has emerged as a novel approach to delivering dance-based therapy in both home-based and clinical settings [6]. Exergames offer the advantages of personalized, adaptable, and enjoyable exercise programs, potentially enhancing patient motivation and adherence [7]. Recent research has highlighted the potential of dance therapy and exergaming to address the complex needs of PD patients. A randomized controlled trial by Duncan and Earheart [4] demonstrated significant improvements in motor function and balance among patients with PD participating in community-based dancing compared with a control group. Furthermore, a study by Barry et al [7] found that exergaming interventions were effective in improving mobility and reducing fall risk in patients with PD.

These findings underscore the importance of further investigating the combined effects of dance therapy and exergaming in PD management. Furthermore, the reliability and performance of current sensing technologies provide physiological data that are useful to monitor the state and the quality of the exercises objectively performed by patients. For example, commercial wearable devices could be easily integrated during rehabilitation sessions to gather information about the heart or breath rate of involved patients and objectively evaluate the metabolic effort. Socially interactive robotic platforms with their interaction and perception capabilities (eg, onboard cameras) are well suited to monitor the posture of patients and support the execution of the exercises through tailored stimuli. A more comprehensive approach may integrate advanced technologies, such as sensor technology for real-time monitoring, artificial intelligence (AI) techniques for personalized difficulty adjustments, and robotic platforms to deliver personalized feedback and enhance the rehabilitation experience.

In this context, the Social Robotics for Active and Healthy Ageing (SI-Robotics) project designed an innovative rehabilitation program targeted at seniors affected by (early stage) PD [8]. The approach relies on the integration of several AI technologies ranging from knowledge representation and reasoning, for user modeling and personalization to machine learning and automated planning (AP) for continuous proactive and adaptive assistance [9]. Leveraging the mentioned interventions based on different types of dance [10,11], the idea is to develop a technology-enhanced, dance-based rehabilitation program where a socially interacting robot and several sensing devices (wearable sensors and 3D cameras mainly) support therapists and patients during the execution of the exercises. This study therefore aims to assess the usefulness of a dance-based physical therapy program enriched by AI-based exergames and contextual robotic assistance in improving motor function, balance, gait, and quality of life in patients with PD. We hypothesized that the proposed technology-enhanced dance therapy would lead to greater improvements in PD symptoms.

Methods

The study is designed as a technical feasibility pilot to test the SI-Robotics system. The entire protocol, including the description of scales, the platform functioning, the training program, and procedures has been previously described in detail [8].

Subjects

A total of 20 patients with PD were selected by the outpatient department at the Clinical Unit of Physical Rehabilitation, Istituto di Ricovero e Cura a Carattere Scientifico Istituto Nazionale Ricovero e Cura per Anziani (IRCCS INRCA). The patients were recruited if they were over 65 years old; able to provide informed consent; had a stage of Hoen and Yahr scale between 1 and 2 [12]; had a Functional Ambulation Category score ≥2 [13]; had a Rankin Scale score ≤3 [14]; had stability of drug treatment for at least 1 month; had a Geriatric Depression Scale 4-item score ≤1 [15]; had a Mini-Mental State Examination ≥24 [16]; and could maintain an upright posture≥30 seconds, evaluated by a trained physiotherapist during the recruitment. The evaluation of compliance with the inclusion and exclusion criteria was performed during the recruitment session. Once we completed this phase, informed consent was obtained. The patient's clinical assessment was performed at the start and the end of the treatment. In particular, the evaluation consisted of the administration of the following scale: measurement of functional state with the Barthel Index [17]; physical performance with Tinetti's Performance-Oriented

Mobility Assessment (POMA) [18], the Short Physical Performance Battery (SPPB) [19], the 6-Minute Walking Test [20], and the Timed Up and Go test (TUG) [21]; evaluation of the quality of life with the 12-Item Short-Form Health Survey (SF-12) [22]; fear of falling with Falls Efficacy Scale-International (FES-I) [23]; and the assessment of the prognosis of PD with the Unified Parkinson Disease Rating Scale – III (UPDRS-III) [24].

Intervention

Figure 1 shows the experimental setting in a protected environment (gymnasium) and the positioning of the technologies, the patient, and the physiotherapist, during the dance-based rehabilitation sessions.

Figure 1. Technological components and actors of Social Robotics for Active and Healthy Ageing (SI-Robotics) rehabilitation sessions.

A total of 16 therapy sessions of 50 minutes were conducted (2 sessions per wk, for 8 wks), involving 2 patients at a time. Cardiac and respiratory activity was monitored during dancing treatments to detect heart rate and breathing frequency. The participants were required to complete at least 80% of the sessions. Each session involved the following activities: (1) breathing, relaxation, and postural harmonization exercises (5 min); (2) active mobility and stretching exercises (5 min); (3) the SI-Robotics intervention (35 min) consisting of the AI-enhanced “Let’s Dance” game, and a socially interacting robot monitoring the execution of the physical exercises of patients; and (4) relaxation exercises (5 min).

After selecting a difficulty level, players are presented as dancers on the screen, along with footprints that suggest the movement to be done. Each task can vary from simple aerobic exercises (side steps, arm raising, hand clapping, etc) to choreographies. At the end of the game session, a score is presented to the patient. This would make a patient aware of the quality of the performance. This score can also be used by the therapist to assess the patient’s performance and the possible increase in the difficulty level of the game.

The next sections describe the technological components of the session in more detail.

The AI-Based Rehabilitation Session

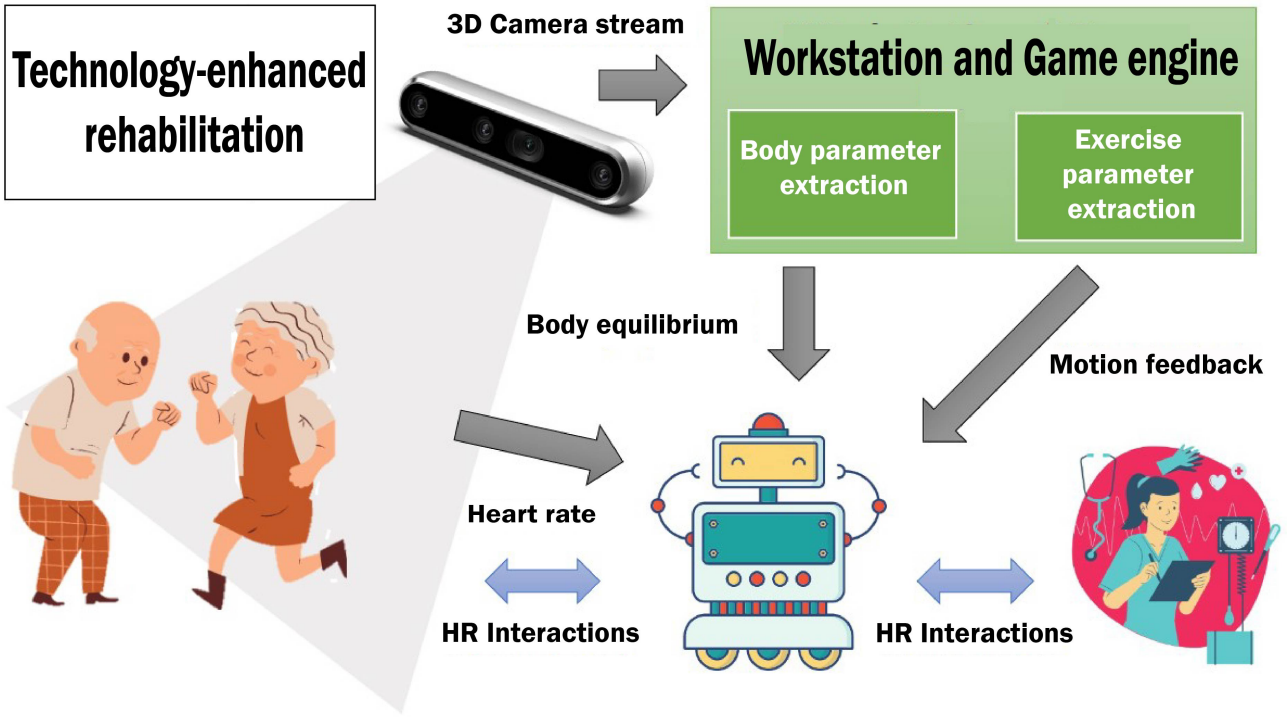
The designed rehabilitation session involves three main actors: (1) a therapist, (2) a patient, and (3) a socially interacting robot. To stimulate engagement, sessions are organized in the shape of exergames where an avatar shows patients the movements they should perform to correctly carry out a rehabilitation exercise (eg, dancing steps). Given a set of data about the needs of a group of patients and about stimulation capabilities of known exercise, a game engine integrates an AI planner [25] and synthesizes exercises by selecting a (sub)set of movements (ie, dancing steps) that best fit the clinical objectives of the session (ie, of the current patient). The exergame is enriched with AP to synthesize suitable physical exercises, contextualized to the clinical objectives of the rehabilitation sessions [25]. Many works in the literature investigate the use of AI in health care and PD [11,26] AI is used for example to predict the wearing-off of symptoms [27], support decisions [28], or early diagnosis of PD [29]. The majority of these works adopt AI solutions based on deep or machine learning and focus on the diagnosis of the disease. Few works investigate the use of AP to support therapists in the synthesis of rehabilitation programs. The study by Gonzalez et al [30], for example, integrates AP into a control architecture to allow a social robot to physically show motions to a patient during physical rehabilitation. Baschieri et al [31] uses AP to synthesize simulation scenarios within a serious game for cognitive rehabilitation. This work pursues an objective similar to ours but in a different clinical scenario.

As shown in Umbrico et al [25] SI-Robotics proposes AP to support the synthesis of physical rehabilitation programs for patients with PD . A key aspect of the developed planning framework is the combined reasoning about spatial and clinical effects of stimuli (ie, motions or dancing steps) needed to synthesize plans that are technically valid and effective from a clinical point of view. Compared with a manual definition of the rehabilitation session, the use of a planner aims to improve the quality, accuracy, and engagement of the resulting rehabilitation programs. A therapist provides a planner with data about the rehabilitation session (song time, song rhythm, and difficulty level) and the clinical objectives. Given this input, the planner decides a sequence of steps, optimized according to an objective function encoding the specified clinical objective. Planned steps are thus chosen according to the rehabilitation needs of the participating patient (personalization).

In addition, several devices enrich the session to extract useful data about the health conditions and the performance of patients.

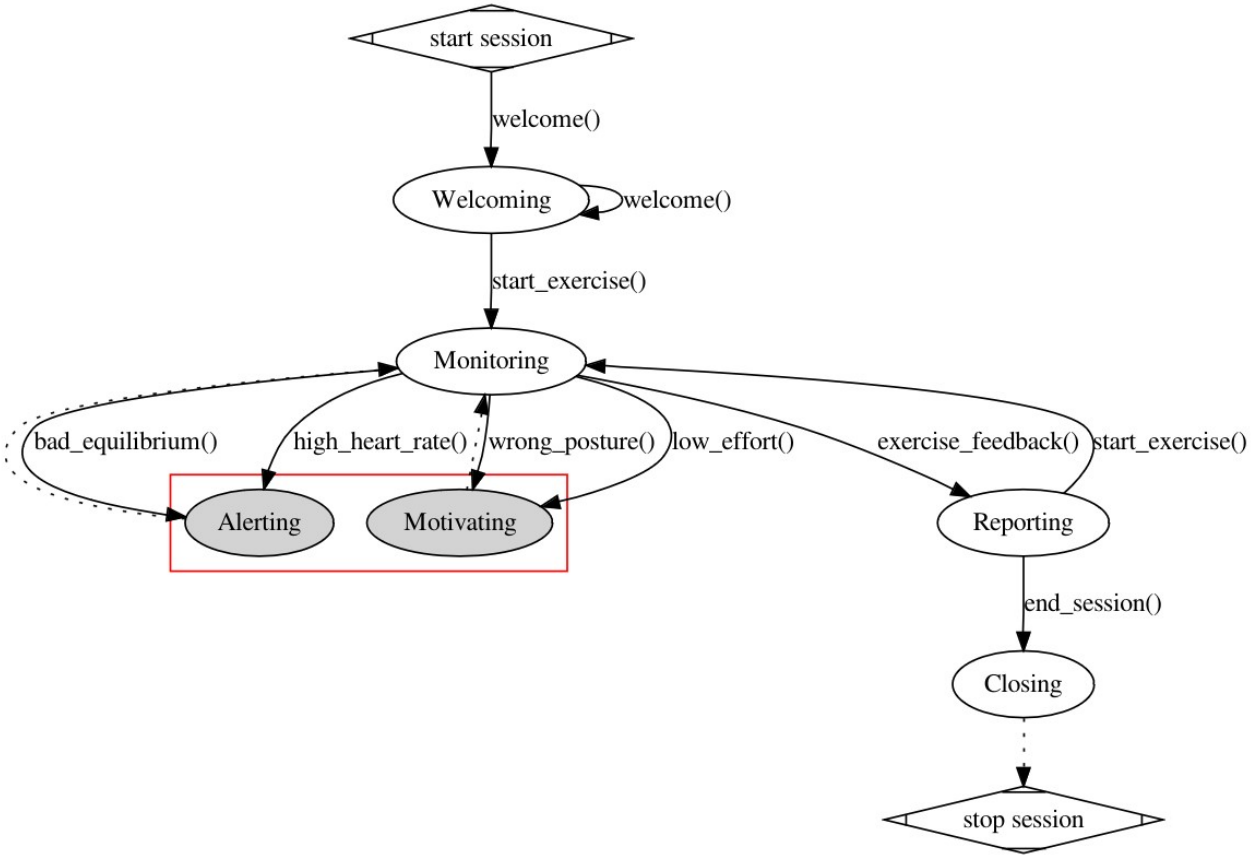
The generated data streams are gathered by the robot that embodies the AI-based reasoning modules. Overall, three types of perception components were considered: (1) wearable sensing devices (eg, sensorized shirts) that constantly produce data streams about physiological parameters of patients (eg, heart rate) [32]; (2) a video-processing component elaborating 3D camera data to extract kinematics about motions and produce data about body posture and body equilibrium of patients and; (3) a video-processing component elaborating 3D camera data to analyze patients' behaviors and produce data about the correctness of performed motions (ie, feedback). Figure 2 below shows a conceptual overview of the designed session pointing out a subset of the main hardware and software components and the data streams generated during the execution of a rehabilitation session.

Figure 2. Automata describing the assistive behavior of the robot during a rehabilitation session. HR: Human-Robot



In addition, a socially interacting robot should support the execution of a session by recognizing the current state of a session according to data gathered from the environment, autonomously detecting events that would trigger different phases, and setting the behavioral goals needed to support a session. The robotic platform consists of a novel social robotic platform designed within SI-Robotics and developed by Co-Robotics [33]. Figure 3 shows the lifecycle determining the assistive behavior of the robot during each rehabilitation session.

Figure 3. Architectural structure of the artificial intelligence–based cognitive control of the robot.



A rehabilitation session starts with a welcoming state where the robot introduces patients to the session. Patients do not know the structure of the rehabilitation and are not familiar with the involved technology. The objective of this state is therefore to prepare patients for the therapy by explaining the structure of the session and the technology used. When all patients are ready to start a session, the robot enters into a "monitoring" state gathering data from the environment to monitor the performance and health state of patients. When a rehabilitation exercise ends the robot enters into the "reporting" state to interact with the therapist to comment on the exercise and the observed performance. This state is especially useful to enrich the subjective experience of the therapist by enhancing the awareness of the therapist with objective feedback on the quality of the exercises. It is indeed meant as a support for the decisions on how to proceed with the session (eg, change or repeat the exercises, difficulty of the next exercise, etc). If the therapist decides to start a new exercise, then the robot enters again into the monitoring state. Otherwise, the robot enters into the "closing" state to finalize the session. In this latter case, the robot interacts with patients to ask their personal feelings about the session and to show a qualitative assessment of their session.

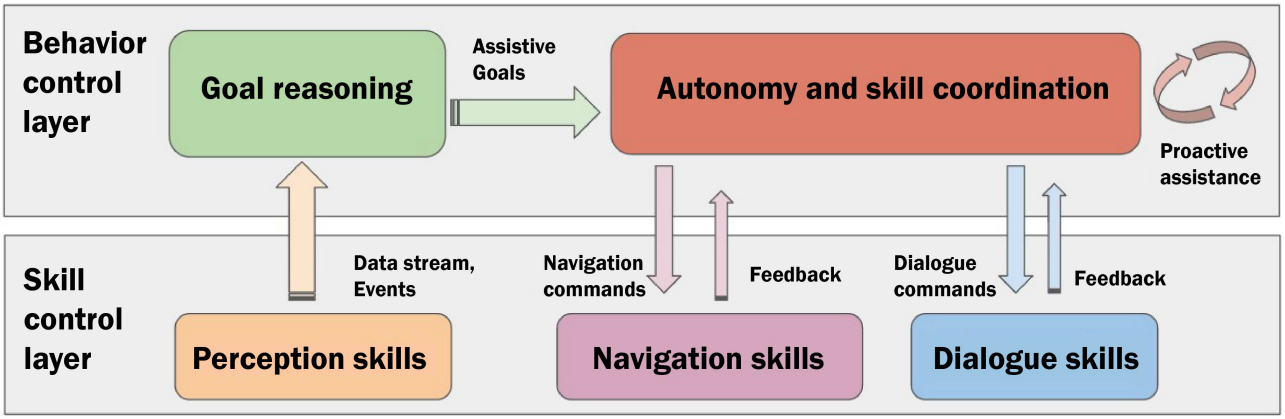
Different types of interaction are foreseen during an exercise, depending on the type of situation recognized by the robot. Two types of interactions have been considered characterized by the motivating and the alerting states in the automata. The motivating phase allows the robot to play the role of a coach during the session stimulating patients to perform better or correcting their behavior. The robot is supposed to enter the motivating phase when it detects a heart rate below some minimum "training threshold" or when it detects a wrong posture of the body, for example, bad alignment or asymmetrical motion of lower or upper limbs.

The alerting phase allows the therapist (and the robot) to intervene when some critical situation concerning the health state of a patient is detected during the session. In such case, the robot is supposed to warn the therapist about the danger and simultaneously interact with the involved patient, even interrupting the exercise if necessary. Specifically, the robot enters the alerting phase when it detects the risk of a fall or an anomalous heart rate for a patient. Both these situations are critical for the considered target of patients and need a prompt intervention.

AI-Based Control of Robotic Skills

A key aspect (and still an open challenge) in the design of autonomous robotic agents is the integration of different AI technologies and Robotics [34,35]. SI-Robotics proposes an AI-based control architecture with twofold objectives: (1) to support the abstraction and reasoning capabilities needed to recognize health-related situations and assistive objectives and (2) to coordinate robotic skills to "act" in the environment and (autonomously) achieve contextualized assistive objectives. Figure 4 shows an overview of the designed architecture with the main functional components involved in the control process. Two main architectural layers are considered and are organized according to a cognitive architecture inspired by the Dual Process Psychological Theory [36].

Figure 4. Designed architecture.



A skill control layer encapsulates the control components responsible for providing the robot with the "low-level" capabilities needed to perceive the environment and interact with the environment. The Navigation Skills component encapsulates functionalities that allow a robot to robustly navigate within the environment and autonomously reach known locations. The Dialog Skills encapsulate natural language processing functionalities that allow a robot to talk with patients and therapists. This component in particular enables an affective interaction [37] by adapting the way the robot talks with a patient to the detected emotional state and known personality traits.

While some level of perception is needed for both navigation and dialogue skills, the Perception Skills component emphasizes the additional capability needed to process data from deployed environmental devices. It encapsulates low-level data processing to provide the higher decisional level with refined information. A behavior control layer supports AI-based control features to contextualize observations, trigger assistive goals, and coordinate underlying skills to implement the desired assistance. The Autonomy and Skill Coordination component encapsulates an AI plan–based controller that supports behavior continuity coordinating robotic skills. The Goal Reasoning component instead is in charge of contextualizing observations to automatically set assistive goals. The combination of goal reasoning and a plan-based controller is the key architectural feature enabling proactive and autonomous goal-oriented behaviors of the robot [38].

The AI-based architectural elements composing the coordination layer of Figure 4 have been embedded into the robotic platform and integrated through the Robot Operating System (ROS) using the ROS Melodic distribution [39]. The coordination component responsible for the synthesis of the assistive behavior has been implemented in the shape of an AI plan–based controller relying on AP. The component uses the open-source framework ROXANNE [40], which implements goal-oriented acting capabilities into an ROS [41]. ROXANNE allows the robot to receive high-level assistive goals and (autonomously) synthesize and execute navigation and dialogue commands or tasks to realize a desired assistive behavior. The goal reasoning component correlates data received from the perception component with the autonomous behavior of the robot. It endows the robot with the cognitive capabilities needed to understand the evolution of a rehabilitation session autonomously select suitable planning goals and consequently decide the assistance needed in a particular context.

Embedded AP models the behavioral constraints needed to correctly support a rehabilitation session. Behavioral constraints are specified in the shape of temporal constraints and require interacting tasks performed through available skills. In this regard, Table 1 shows the modeled assistive goals and the parameters defined to contextualize interactions. Furthermore, the table briefly describes the behavioral constraints specified in the model to correctly implement the desired assistance and support the associated goal. It is worth noting that AI planning facilitates robot programming since it supports an "easy specification" of desired behavioral dynamics without hard-coding the implemented skills.

Table . Acting goals supported by the robot-embedded controller to synthesize assistive behaviors during a rehabilitation session.

Goal	Interaction parameters	Interaction parameters
Welcoming	• Therapist: string • Patient: string • Gender: string • Novel: boolean	The robot moves from its current location to the welcoming area to call the specified patient and take patient to the dressing area to wear the sensorized shirt. Then it guides the patient to the rehabilitation area to start the session. If the patient is new to the session (flag novel set to true) the robot explains the organization of the rehabilitation and the functioning of the devices. Otherwise, the robot shows data about the last session to motivate the patient for the current one.
Exercise start	__[a]	When an exercise begins the robot starts moving around the rehabilitation area and monitoring patients' state by collecting physiological, body posture, and performance data.
Exercise report	• Patient: string • Gender: string • Score: double • Past_score: double • Global_score: double	When an exercise ends the robot moves close to a patient to show a brief report about the patient performance. The robot shows the achieved score and (if available) compares it to the average score of the patient in the past and the average score of other patients. This would make a patient aware of the quality of the performance.
Low heart rate and high heart rate	• Therapist: string • Patient: string • Gender: string • Heart_rate: double	The robot periodically analyzes trends of gathered data about the heart rate of a patient. Thresholds are parametric and computed according to the age of the patient as follows: HR_max=80% (220 – age) HR_min=40% h_max The objective of the session is to keep the heart rate of patients within HR_max and HR_min to stimulate a proper metabolic effort. In the case of low heart rate (i.e., value below HR_min) the robot implements a motivational behavior asking a patient to improve the performance. In case of high heart rate (i.e., value above HR_max), the root implements an assistive behavior alerting the therapist and asking the patient to reduce the performance
Bad posture	• Patient: string • Gender: string • Tilt: integer in [0, 1] • Arms: integer in [–1, 1] • Legs: integer in [–1, 1]	The robot constantly monitors the motions and the inclination of patients. If anomalous kinematics parameters are detected, for example, wrong inclinations of the body or wrong alignment of arms or legs, the robot implements a motivational behavior to correct the body posture of a patient and thus stimulate correct motions.
Bad equilibrium	• Therapist: string • Patient: string • Gender: string • Lateral: integer in [–1,1] • Frontal: integer in [–1,1]	In addition to the body posture, the robot constantly monitors the equilibrium of patients to prevent dangerous falls during physical therapy. If dangerous equilibrium conditions are detected from camera data (eg, the center of mass is outside the patient's base) the robot implements an assistive behavior to promptly notify the therapist and warn the patient about the danger or falling.

[a]Not applicable.

Outcomes

All assessment procedures adhere to a standardized protocol. Specifically, the primary focus of the study revolves around enhancing balance, and gait, and alleviating the fear of falling among elderly patients with PD. This is gauged through the utilization of the 3 POMA scales (POMA balance, POMA Gait, and POMA Total) after the 10 treatment sessions, as a result of the Irish dance intervention. In addition, secondary measures include evaluating the gait speed of elderly patients with PD, their fear of falling (assessed via FES-I), their physical

performance (SPPB), their autonomy in daily living activities (UPDRS-III), and their overall physical and psychological well-being (SF-12) together with the evaluation of the Unified Theory of Acceptance and Use of Technology (UTAUT) that is composed by 10 subscales (anxiety; attitude; facilitating conditions; intention to use; perceived adaptability; perceived enjoyment; perceived ease of use; perceived usefulness; social influence; and trust).

Statistical Analysis

Continuous variables were presented as either mean and SD or median and IQR, depending on their distribution, which was determined using the Kolmogorov-Smirnov test. Categorical variables were expressed as absolute numbers and percentages. To test statistically significant differences ($P<.050$) between pre- and postconditions, Wilcoxon signed-rank test (for non-normal distribution) or paired test (for normal distribution) were used, alongside simple descriptive statistics such as means, medians, and SDs as appropriate. The statistical analysis was performed using SPSS software.

Ethical Considerations

The study was approved by the Ethics Committee of the Istituto Nazionale Ricovero e Cura per Anziani, (IRCCS INRCA) on June 17, 2021 (CE INRCA 21004). The protocol is registered on ClinicalTrials.gov with trial registration number NCT05005208 (October 23 , 2023). All participants signed the informed consent and data processing consent. The data are anonymised so that the identity of the subject cannot be traced. No compensation is provided for participation in the study.

Results

Demographic and clinical data of the patients are reported in Table 2. Two participants dropped out because they did not complete the rehabilitation program.

The CONSORT (Consolidated Standards of Reporting Trials) flowchart is shown in Figure 5.

Gender differences were not statistically significantly different in all scales used to select the sample.

Table . Baseline demographic and clinical profile.

		Total (n=18)	Male (n=10)	Female (n=8)	*P* value
Age (years), mean (SD)		75.3 (5.5)	73.7 (5.4)	77.2 (5.2)	.18
Marital status, n (%)					.48
	Married	15 (83.3)	9 (90)	6 (75)	
	Single	1 (5.5)	0 (0)	1 (12.5)	
	Widowed	2 (11.2)	1 (10)	1 (12.5)	
Educational level, n (%)					.17
	Primary education	4 (22.2)	1 (10)	3 (37.5)	
	Secondary education	10 (55.6)	6 (60)	4 (50)	
	University or more	4 (22.2)	3 (30)	1 (12.5)	
Hoehn and Yahr score, mean (SD)		1.8 (0.3)	1.9 (0.3)	1.7 (0.4)	.42
Rankin Scale score, mean (SD)		1.6 (0.9)	1.4 (0.8)	1.8 (1.1)	.33
GDS[a], mean (SD)		3.0 (0.7)	2.9 (0.7)	3.2 (0.7)	.33
FAC[b], mean (SD)		4.6 (0.6)	4.7 (0.4)	4.5 (0.74)	.50
MMSE[c], mean (SD)		29.4 (0.9)	29.7 (0.6)	29.1 (0.7)	.22
Barthel Index score, mean (SD)		95.5 (5.6)	94.5 (6.8)	96.8 (3.7)	.39

[a]GDS: Geriatric Depression Scale.

[b]FAC: Functional Ambulation Category.

[c]MMSE: Mini-Mental State Examination.

Figure 5. The CONSORT (Consolidated Standards of Reporting Trials) flowchart.

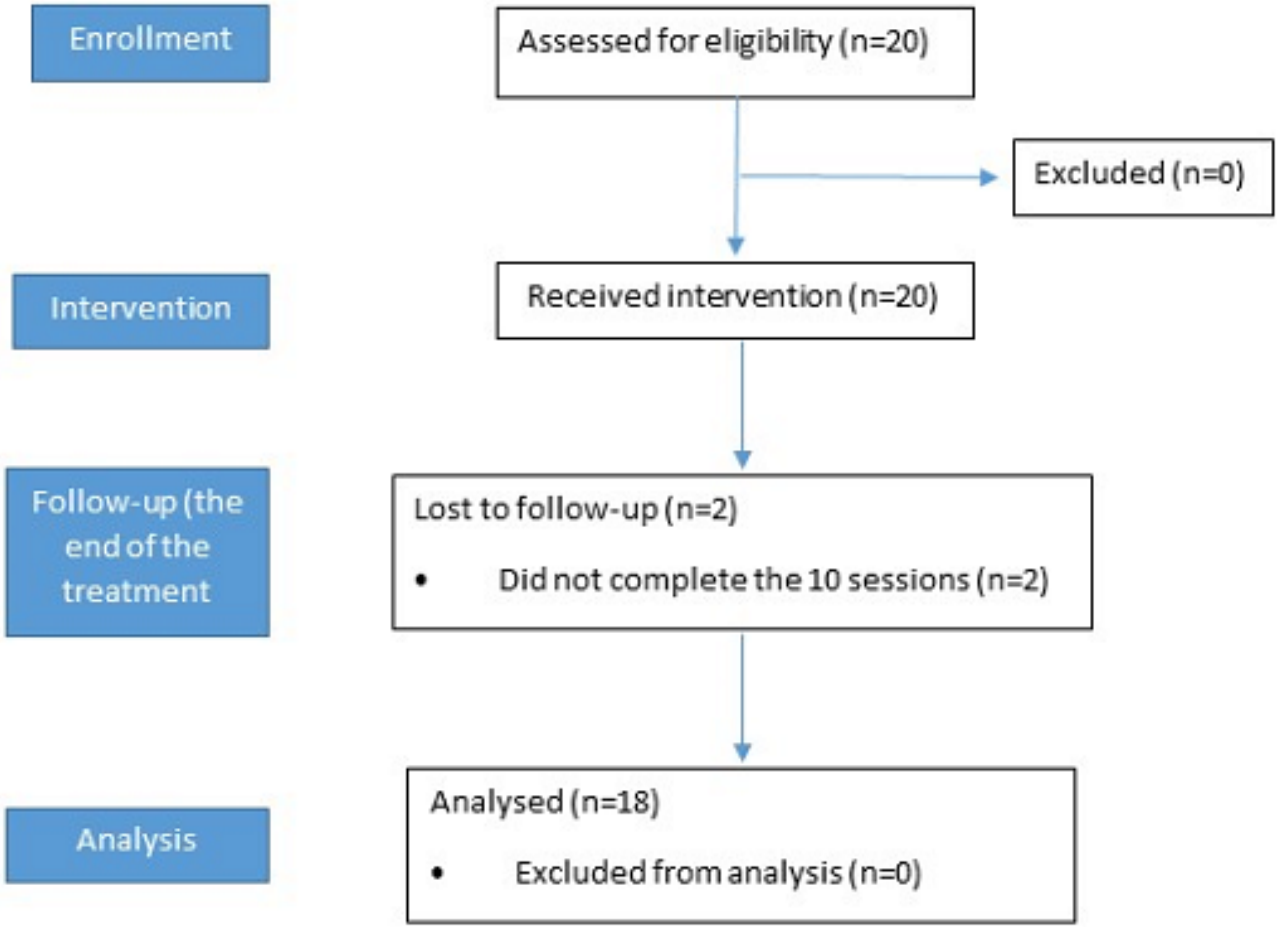


Table 3 shows differences between pre- and postintervention on the functional state scales with the UPDRS-III and the SPPB, gait and balance performance on Tinetti POMA Gait and POMA Balance, evaluation of quality of life with SF-12 and its subscores (physical component score and mental component score), fear of falling (FES-I) together with the TUG execution time, the meters covered during the 6-Minute Walking Test and the gait speed.

Statistical analysis revealed a significant effect on UPDRS-III and TUG together with improvements in the POMA scale, both on balance and gait aspects, and in SPPB. However, for the POMA and SPPB scales, there was a low Cohen *d* coefficient, underlining a probable effect of the low sample size on these results. In contrast, the effect size for UPDRS-III and TUG was high (>0.70), highlighting the usefulness of the rehabilitation intervention on the motor symptoms of PD also in our small sample.

Table . Mean (SD) values of the mean of pre- and postintervention scores on the UPDRS-III[a], SPPB[b], POMA[c] (total, gait and balance), SF-12[d] (total, physical, and mental component score), FES-I[e], TUG[f] execution time, 6MWT[g], and gait speed. Pre-post and between-group comparisons are reported for each score (P<.05). The effect size (Cohen d) is also reported.

		Preintervention scores, mean (SD)	Postintervention scores, mean (SD)	P value	Cohen d
UPDRS-III		13.56 (1.85)	13.83 (1.85)	.01[h]	−0.73
SPPB		8.83 (2.61)	10.39 (2.45)	.02[h]	0.10
POMA					
	POMA Total	24.11 (3.92)	26.28 (2.74)	.001[h]	−0.07
	POMA Gait	9.83 (2.30)	10.94 (1.55)	.01[h]	−0.02
	POMA Balance	14.28 (2.16)	15.33 (1.37)	.01[h]	−0.10
SF-12					
	SF-12-Tot[i]	31.28 (1.99)	32.33 (2.42)	.10	−0.20
	PCS-12[j]	13.56 (1.84)	13.83 (1.85)	.49	−0.23
	MCS-12[k]	17.72 (1.22)	18.50 (1.91)	.12	−0.16
FES-I		10.78 (1.92)	10.67 (2.22)	.83	−0.29
TUG (s)		11.0 (3.91)	9.19 (3.14)	.002[h]	−0.82
6MWT (m)		361.50 (99.33)	373.72 (98.67)	.40	−0.19

[a]UPDRS-III: Unified Parkinson Disease Rating Scale – III.

[b]SPPB: Short Physical Performance Battery.

[c]POMA: Performance Oriented Mobility Assessment.

[d]SF-12: 12-Item Short-Form Health Survey.

[e]FES-I: Falls Efficacy Scale–International.

[f]TUG: Timed Up and Go test.

[g]6MWT: 6-Minute Walking test.

[h]P values from matched-pairs Student t test.

[i]SF-12-Tot: 12-Item Short-Form Health Survey total score.

[j]PCS-12: 12-Item Short-Form Health Survey physical component score

[k]MCS-12: 12-Item Short-Form Health Survey mental component score.

Table 4 reports the scores of the subscales of UTAUT.

The analysis of the UTAUT subscales provided valuable insights into users' perceptions and interactions with the system. In particular, attitude, perceived adaptability, enjoyment, ease of use, usefulness, and social influence were generally positive.

Table . Mean (SD) of the mean of the Unified Theory of Acceptance and Use of Technology (UTAUT) subscales scores.

UTAUT subscales		Score, mean (SD)	Range
Anxiety (ANX)	Evoking anxious or emotional reactions when using the system.	7.4 (4.2)	0 - 20
Attitude (ATT)	Positive or negative feelings about the appliance of the technology	11.2 (2.5)	0 - 15
Facilitating conditions (FC)	Objective factors in the environment that facilitate using the system	2.6 (1.7)	0 - 15
Intention to use (ITU)	The outspoken intention to use the system over a longer period in time	3 (0)	0 - 10
Perceived adaptability (PAD)	The perceived ability of the system to be adaptive to the changing needs of the user.	10.5 (3.0)	0 - 15
Perceived enjoyment (PENJ)	Feelings of joy or pleasure associated by the user with the use of the system.	18.2 (2.2)	0 - 25
Perceived ease of use (PEOU)	The degree to which the user believes that using the system would be free of effort	18.1 (3.8)	0 - 25
Perceived usefulness (PU)	The perceived ability of the system to perform sociable behavior.	11.4 (2.9)	0 - 15
Social influence (SI)	The user's perception of how people who are important to him think about him using the system	8 (2.4)	0 - 10
Trust	The belief that the system performs with personal integrity and reliability.	7.5 (1.8)	0 - 10

Discussion

Principal Findings

This study aims to investigate the usefulness of the SI-Robotics intervention based on AI robotic assistance and exergame stimulation, in the context of PD. This study aims to assess the ability of a dance-based physical therapy program enriched by AI-based exergames and contextual robotic assistance in improving motor function, balance, gait, and quality of life in patients with PD. The findings of this study demonstrate the potential usefulness of a dance-based physical therapy program using a robotic platform to deliver exergames in improving motor function, balance, gait, and quality of life in patients with PD. Results suggest that integrating dance therapy with engaging technology may lead to greater improvements in PD symptoms compared with conventional physical therapy alone. Although the statistical analysis revealed significant improvements in motor function, balance, and gait (eg, UPDRS-III, POMA, and TUG scores), the effect sizes for several outcome measures were relatively small (Cohen d<0.2 for POMA and SPPB scales). This suggests that, while the observed changes were statistically significant, the practical impact of the intervention on certain motor and functional outcomes may be limited. These small effect sizes could be partly attributed to the small sample size, which may have reduced the power to detect larger effects.

This study adds to the growing body of research supporting the use of dance therapy and exergaming as adjunctive treatments for PD. Previous studies have shown that both dance therapy and exergaming can independently improve motor function, balance, and mobility in patients with PD [4,7]. By combining these approaches, our intervention aimed to target the multifaceted nature of PD symptoms, including motor, cognitive, and psychosocial aspects.

The results are consistent with previous findings demonstrating the benefits of dance therapy and exergaming in PD management. For example, Duncan and Earheart [4] reported significant improvements in motor function and balance among patients with PD participating in community-based dancing, while Barry et al [7] found that exergaming interventions were effective in improving mobility and reducing fall risk in patients with PD. These studies, along with ours, highlight the potential of integrating dance therapy with exergaming to address the complex needs of patients with PD.

One novel aspect of our intervention is the use of the SI-Robotics system, a robotics-based platform designed to engage patients with PD in Irish set dancing. This innovative approach combines the physical and cognitive benefits of dance therapy with the interactive and adaptable nature of exergaming. By incorporating personalized avatars and choreography, the "Let's Dance" game provided a stimulating and enjoyable exercise experience for participants, potentially enhancing motivation and adherence to the intervention.

Regarding the analysis of technology acceptance among the population studied, the results indicate a generally positive perception and interaction with technology. In particular, users displayed a positive attitude towards the technology, indicating

favorable feelings toward it. They also found the system adaptable, enjoyable, easy to use and useful showing that users experienced pleasure while using the system. Finally, trust in the system was moderately high, indicating that users believed it to be reliable and trustworthy. These highlight how the system successfully meets user expectations by offering an engaging, straightforward, and beneficial experience.

Our study focused on elderly patients with PD with mild to moderate disease severity, as reflected by their scores on the Hoen and Yahr scale, Functional Ambulation Category, Rankin Scale, Geriatric Depression Scale, and Mini-Mental State Examination. These inclusion criteria aimed to ensure that participants were physically and cognitively capable of engaging in the intervention safely and effectively. Future research could explore the applicability of our intervention to a broader range of patients with PD , including those with more advanced disease stages.

Limitations of our study include the small sample size and lack of a control group for comparison. While our results provide preliminary evidence of the usefulness of the intervention, larger-scale randomized controlled trials are needed to confirm these findings and establish the optimal dosage and timing of dance-based physical therapy with exergames for PD management. In addition, longer-term follow-up assessments could help evaluate the sustainability of the intervention effects over time.

Conclusions

In conclusion, this study highlights the potential of integrating dance therapy with exergaming integrated with an interactive robotic platform as a novel approach to improving motor function, balance, gait, and quality of life in patients with PD. The SI-Robotics intervention offers a promising avenue for future research and clinical practice in the management of PD symptoms. To strengthen the validity of the current findings and ensure their broader applicability, future research will focus on replicating the study with a larger sample. This will help to verify the generalizability of the results providing a more comprehensive understanding of the observed effects. Moreover, further studies are warranted to explore the long-term effects and feasibility of implementing this intervention in diverse clinical settings.

Acknowledgments

The study has received funding under the project Social Robotics for Active and Healthy Ageing (SI-Robotics (ARS01_01120), funded by the Italian Ministry of Education, Universities and Research, under the National Operational Program Area, Technologies for Living Environments.

Abstract

Background: Serum levels of silent information regulator 6 (SIRT6), a key biomarker of aging, were identified as a predictor of coronary artery disease (CAD), but whether SIRT6 can distinguish severity of coronary artery lesions in older adult patients is unknown.

Objectives: This study developed a nomogram to demonstrate the functionality of SIRT6 in assessing severity of coronary artery atherosclerosis.

Methods: Patients aged 60 years and older with angina pectoris were screened for this single-center clinical study between October 1, 2022, and March 31, 2023. Serum specimens of eligible patients were collected for SIRT6 detection by enzyme-linked immunosorbent assay. Clinical data and putative predictors, including 29 physiological characteristics, biochemical parameters, carotid artery ultrasonographic results, and complete coronary angiography findings, were evaluated, with CAD diagnosis as the primary outcome. The nomogram was derived from the Extreme Gradient Boosting (XGBoost) model, with logistic regression for variable selection. Model performance was assessed by examining discrimination, calibration, and clinical use separately. A 10-fold cross-validation technique was used to compare all models. The models' performance was further evaluated on the internal validation set to ensure that the obtained results were not due to overoptimization.

Results: Eligible patients (n=222) were divided into 2 cohorts: the development cohort (n=178) and the validation cohort (n=44). Serum SIRT6 levels were identified as both an independent risk factor and a predictor for CAD in older adults. The area under the receiver operating characteristic curve (AUROC) was 0.725 (95% CI 0.653 - 0.797). The optimal cutoff value of SIRT6 for predicting CAD was 546.384 pg/mL. Predictors included in this nomogram were serum SIRT6 levels, triglyceride glucose (TyG) index, and apolipoprotein B. The model achieved an AUROC of 0.956 (95% CI 0.928 - 0.983) in the development cohort. Similarly, in the internal validation cohort, the AUROC was 0.913 (95% CI 0.828 - 0.999). All models demonstrated satisfactory calibration, with predicted outcomes closely aligning with actual results.

Conclusions: SIRT6 shows promise in predicting CAD, with enhanced predictive abilities when combined with the TyG index. In clinical settings, monitoring fluctuations in SIRT6 and TyG may offer valuable insights for early CAD detection. The nomogram for CAD outcome prediction in older adult patients with angina pectoris may aid in clinical trial design and personalized clinical decision-making, particularly in institutions where SIRT6 is being explored as a biomarker for aging or cardiovascular health.

Introduction

The global burden of ischemic heart disease from 1990 to 2019 reached staggering figures, with an estimated 9.14 million deaths attributed to coronary artery disease (CAD) in 2019 alone, affecting approximately 197 million individuals worldwide [1]. China witnessed a notable surge in CAD-associated mortality during this period, accounting for 38.2% of the global rise. By 2017, CAD-related deaths in China had skyrocketed by 1.12 million, representing an astonishing 184.1% increase compared with that of 1990 [2,3]. As of 2019, China was the global leader in CAD-related deaths, with 1.87 million reported cases [4]. By 2029, a 64% increase in CAD cases is expected in China

compared with 2020. As a dynamically evolving condition, CAD significantly contributes to the development of major adverse cardiovascular events, such as myocardial infarction, stroke, and cardiovascular mortality [5].

Aging, an independent risk factor for CAD, is characterized by a progressive decline in coronary artery and microvascular function, resulting in altered myocardial perfusion and increased myocardial injury [6]. CAD predominantly affects middle-aged and older adult populations, particularly people aged 60 years and older, with a prevalence exceeding 70%. Notably, the older adult population in China, aged 65 years and older, reached 220 million in 2023, constituting 15.4% of the nation's population and approximately 26.8% of the global older adult population [7]. The aging demographic in China is expanding rapidly, with nearly 40 million individuals aged 80 years and older in 2022, accounting for approximately 2.7% of the total population of China. Hence, China is predicted to enter a super-aged society by 2030, with the older adult population comprising more than 20% of the total population [8]. By 2084, it is estimated that half of China's population will be older adults. A higher mortality rate has been observed among Chinese older adults with CAD, with the majority of deaths occurring in people aged 75 years and older [9]. Despite these trends, research on CAD has often overlooked the specific needs of the older adult population. In China, approximately 300 million people suffer from chronic diseases, with half of them being aged 65 years or older. The older adult population often presents with atypical clinical symptoms, multiple comorbidities, and prolonged use of medications, all of which amplify the risk of cardiovascular disease [10,11]. Previous studies have indicated that therapeutic interventions in the early stages of CAD can reduce its incidence and improve prognosis [12,13], underscoring the necessity for noninvasive methods for identifying predictive factors for CAD.

Silent information regulator 6 (SIRT6), a member of the nicotinamide adenine dinucleotide–dependent histone deacetylase family, plays a crucial role in aging and aging-related diseases by maintaining telomerase stability and metabolic homeostasis, as well as regulating oxidative stress [14]. Recent evidence has highlighted the protective properties of SIRT6 against CAD in preserving endothelial function, inhibiting inflammatory responses, and regulating glucose and lipid metabolism. Hence, a decline in serum SIRT6 levels has emerged as an independent risk factor for CAD [15], warranting further investigation of its diagnostic and predictive value in older adult patients. Existing risk assessment models, such as the Pooled Cohort Equations model and the Systematic Coronary Risk Estimation model, were primarily developed based on Caucasian and African American populations and lack specific biomarkers and demonstrate poor calibration when applied to the Chinese population [16]. Given these ethnic differences, there is an urgent need for tailored risk assessment models in cardiovascular disease prevention, particularly in diverse populations such as China.

In this study, we aimed to develop a nomogram for predicting outcomes in older adults presenting with clinical symptoms suggestive of CAD. We hypothesized that a combination of baseline SIRT6 levels with clinical parameters could improve the evidence-based selection of candidates for this marker and facilitate clinical decision-making, resulting in its potential implementation in clinical trials.

Methods

Study Design and Participants

In this single-center study, a nomogram was developed for predicting the outcomes of potential cases with CAD and was validated using data from Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine. Patients aged 60 years or older who were diagnosed with angina pectoris were screened between October 1, 2022, and March 31, 2023. The Judkins method [17] was used for performing coronary angiography (CAG) via the radial or femoral artery. The angiographic results underwent joint assessment by 3 experienced cardiovascular specialists (WFS , ZBZ, and JWN). The severity of stenosis in the major coronary arteries, including the left anterior descending branch (LAD), left circumflex artery, right coronary artery, and left main coronary artery, was evaluated, with CAD defined as ≥50% stenosis in any 1 vessel and coronary atherosclerosis (CAS) as <50% stenosis in all vessels.

Eligible participants were individuals aged 60 years or older who presented with chest pain and had been evaluated by a specialist, resulting in a preliminary diagnosis of CAD with an indication for CAG. Participants must have no prior history of CAG, percutaneous coronary intervention, or coronary artery bypass grafting. Furthermore, informed consent must be obtained for the collection of biological samples, with blood samples obtained prior to CAG. Participants must also have coronary artery stenosis as confirmed by the CAG results. Exclusion criteria included recent acute infections, gastrointestinal bleeding, surgical procedures, or trauma within the past 6 months. Individuals were also excluded if they had positive viral markers, including hepatitis B surface antigen, hepatitis B core antibody with hepatitis B virus–DNA of the detection threshold or greater, positive hepatitis C virus antibody with hepatitis C virus–RNA of the upper limit of normal or greater, or positive HIV antibody. Severe cardiac conditions also warranted exclusion, including decompensated heart failure, significant valvular heart disease within the past 6 months, notable electrocardiographic abnormalities (eg, any degree of atrial fibrillation, second-degree type II or third-degree atrioventricular block, or corrected QT interval exceeding 470 milliseconds in females or 450 milliseconds in males), uncontrolled symptomatic arrhythmias, cerebrovascular events or transient ischemic attacks within the past 6 months, a history of malignancy or autoimmune diseases, or severe liver or renal disorders unrelated to the study condition.

Upon admission, patients were assessed for CAD severity using the Gensini score, an angiographic tool for grading coronary artery lesions [18]. Serum specimens were collected from eligible patients for the detection of SIRT6 levels by enzyme-linked immunosorbent assay. Clinical data and the complete CAG inspection results of these participants were also collected.

Ethical Considerations

The study protocol was approved by the human ethics committee of Ruijin Hospital (KY2021-108 Ruijin Hospital). It adhered to strict data confidentiality measures in compliance with the Helsinki Declaration and the institutional guidelines and reporting studies conducted using routinely collected observational data. Participants provided written informed consent at the time of data collection.

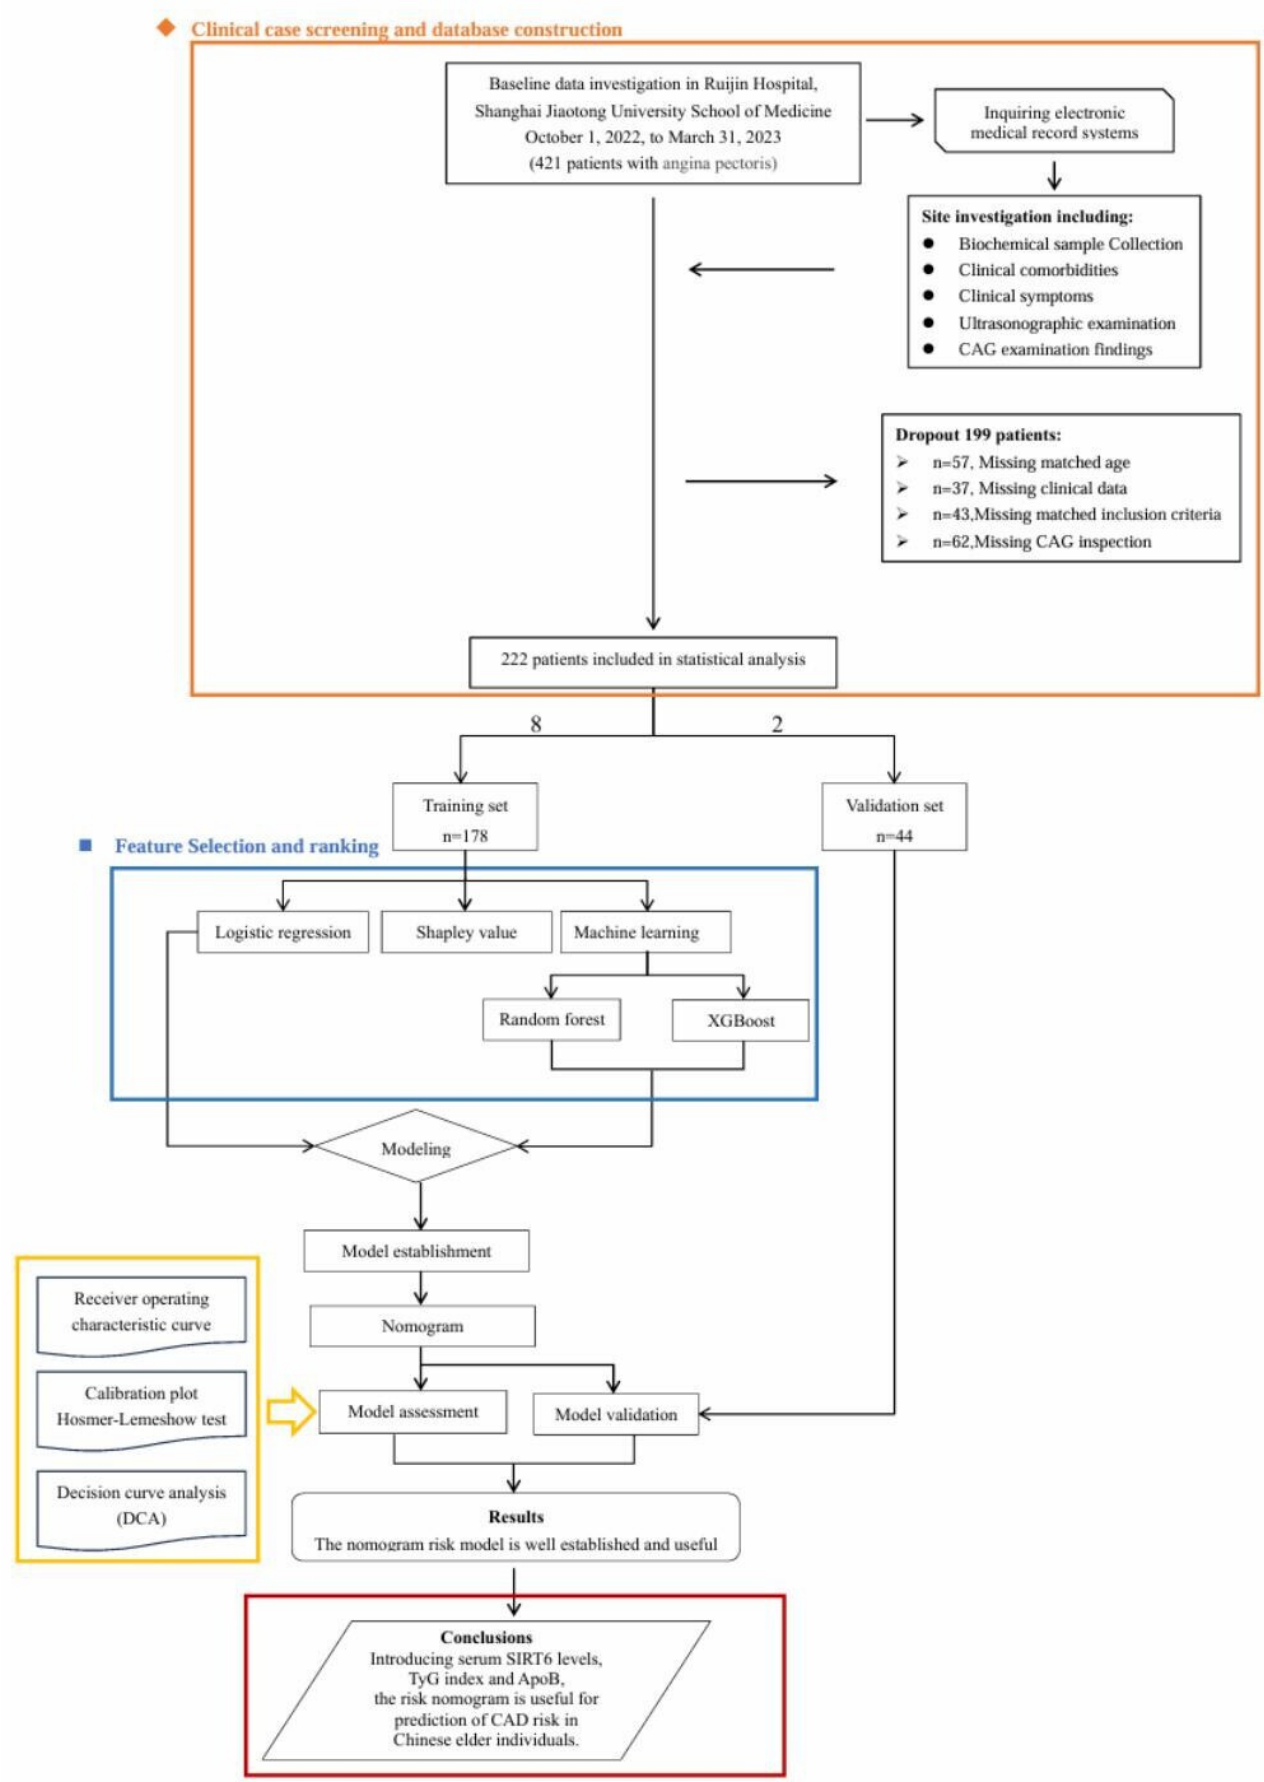
Selection Bias

Several rigorous measures were implemented to address potential selection bias in this study. Stringent inclusion and exclusion criteria were carefully defined and applied to ensure a well-characterized and homogeneous study population. Furthermore, random sampling techniques were used where appropriate, and blinding in outcome assessment was ensured to minimize bias in both participant selection and data interpretation. These strategies were designed to enhance the internal validity and robustness of our study results.

Data Collection

All recruited patients were divided into 2 cohorts, the development cohort and the validation cohort, in an approximate ratio of 8:2. Then, predefined criteria were applied to ensure cohort comparability. A total of 29 pretherapeutic parameters were collected, including demographic characteristics, initial symptoms, history of hypertension and diabetes mellitus, baseline clinical status, and baseline laboratory test results. Finally, 3 out of 26 collected parameters were tested as putative predictors for outcomes in the models. Three putative predictors allowed for 9-10 events per predictor for the primary outcome in the training cohort, meeting the recommended minimal number of events per predictor. These putative predictors were selected based on previous research demonstrating their potential prognostic value in CAD and the investigators' (WFS, ZYC, and JWN) clinical experience with CAD. The study flowchart is shown in Figure 1.

Figure 1. Study flowchart. ApoB: apolipoprotein B; CAD: coronary artery disease; CAG:coronary angiography; SIRT6: silent information regulator 6; TyG: triglyceride glucose; XGBoost: Extreme Gradient Boosting.



Statistical Analysis

Variable Selection

In this study, IBM SPSS Statistics (version 26.0; IBM Corp) software was used for baseline description and logistic regression (LR) analysis. Continuous variables were presented as mean (SD), while categorical variables were expressed as percentages (n [%]). Normality was assessed using the Shapiro-Wilk test, with $P>.05$ indicating adherence to normal distribution. For normally distributed variables, an intergroup analysis was conducted using the *t* test, while nonnormally distributed data were compared using the Wilcoxon rank sum test. Features with >30% missing values were removed. The remaining 29 features were collected for further processing. For features with missing values of <10%, median or mean imputation was used. Those with 10% - 20% missing values were imputed by the "MissForest" package in R (R Foundation for Statistical Computing). Random forest and Extreme Gradient Boosting (XGBoost) algorithms were implemented via R statistical software (version 4.3.2; R Foundation for Statistical Computing). Receiver operating characteristic (ROC) curves were plotted using the "pROC" package, while nomograms were constructed using the "rms" and "regplot" packages. The "val.prob" function was used for refining calibration curve plots and Hosmer-Lemeshow tests, while the "dcurves" function facilitated decision curve analysis (DCA). All statistical tests were 2-tailed, with $P<.05$ considered statistically significant. Feature ranking was obtained using Shapley Additive Explanation, Gini, and Gain values, respectively. A 10-fold cross-validation strategy was applied to develop the data set into training, validation, and test sets.

Model Building and Visualization:

Three methodologies, including LR, random forest, and XGBoost, were used for model building. All analyses were conducted using the statistical software package R (version 4.3.2). The data from the Ruijin Hospital of Shanghai Jiao Tong Medical University were used as the training set and internal validation set for model development and verification. Binary LR, random forest, and XGBoost models were constructed using the training data to classify patients into those with CAS and those with CAD. The XGBoost model exhibited the highest comprehensive discriminant ability [19] and therefore was selected for further analysis. The final model was visualized as a column line chart to address issues of poor machine learning interpretability and consequent low clinical use.

Model Comparison

Accuracy, precision, recall, and F_1-score were used to evaluate the performance of the multiclassification model. The model error was further analyzed using a confusion matrix. Discrimination, calibration, and clinical use between the nomogram and the variables incorporated into the nomogram were assessed in both the training and validation sets, respectively. ROC curves, calibration curves, and DCA plots were plotted, and the areas under the ROC curves (AUROCs) were compared using the Delong test. Calibration was evaluated using the Hosmer-Lemeshow test.

Results

Characteristics of the Training and Validation Sets

The final study cohort comprised 222 patients, with 178 allocated to the training set and 44 to the validation set. The demographic characteristics and clinical results of patients in both sets are summarized in Table 1. There were 23.87% (53/222) of patients in the CAS group and 76.13% (169/222) of patients in the CAD group. There were significant differences in the low-density lipoprotein cholesterol (LDL-C), apolipoprotein B (ApoB), apolipoprotein E (ApoE), fasting blood glucose (FBG), hemoglobin A_{1c} (HbA_{1c}), Gensini score, TyG index, and atherogenic index of plasma (AIP) between the CAS and CAD groups ($P<.05$). Specifically, the CAD group exhibited a higher TyG index (12.4 [SD 1.38]) and AIP (0.10 [SD 0.31]) than the CAS group (10.9 [SD 0.54], 0.00 [SD 0.27]), as shown in Table 1. Significant differences were also observed in categorical variables, such as sex, history of diabetes, clinical symptoms, segmental vascular lesions (ie, LAD, left circumflex artery, left main coronary artery, and right coronary artery), and 10-year cardiovascular risk between the CAS and CAD groups ($P<.05$).

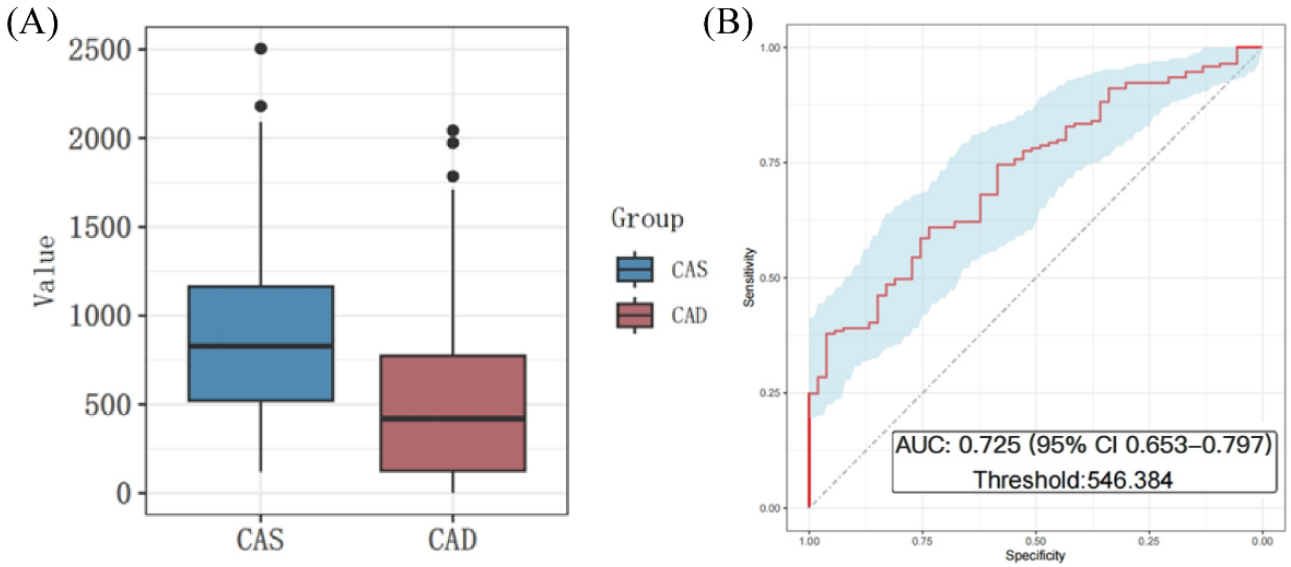
[a]Variables of significance (*$P \leq .05$, ** $P \leq .01$, and *** $P \leq .001$).
[b]CAS, coronary atherosclerosis.
[c]CAD: coronary artery disease.
[d]SBP: systolic pressure.
[e]DBP: diastolic blood pressure.
[f]hs-CRP: hypersensitive C-reactive protein.
[g]CysC: cystatin c.
[h]eGFR: estimated glomerular filtration rate.
[i]mALB: microalbumin.
[j]cTnI: troponin I.
[k]proBNP: pro-B-type natriuretic peptide.
[l]LDL-C: low-density lipoprotein cholesterol.
[m]Lp(a): lipoprotein(a).
[n]sLDL: small dense low-density lipoprotein.
[o]ApoA1: apolipoprotein A1.
[p]ApoB: apolipoprotein B.
[q]ApoE: apolipoprotein E.
[r]FBG: fasting blood glucose.
[s]HbA_{1c}: hemoglobin A_{1c}.
[t]FINS: fasting insulin.
[u]CP: C-peptide.
[v]LAD: left anterior descending branch.
[w]RCA: right coronary artery.
[x]LCX: left circumflex artery.
[y]LM: left main coronary artery.
[z]N/A: not applicable.
[aa]SIRT6: silent information regulator 6.
[ab]TyG: triglyceride glucose.
[ac]AIP: atherogenic index of plasma.

Circulating SIRT6 Levels in Patients

To investigate the potential difference in serum SIRT6 levels between the CAD and CAS groups, the enzyme-linked immunosorbent assay was used to determine the SIRT6 levels in serum samples. A significant reduction in serum SIRT6 levels was observed in the CAD group (495 [SD 443] pg/mL) compared with the CAS group (866 [SD 510] pg/mL) (Figure 2A). To further assess the diagnostic potential of serum SIRT6 as a biomarker for distinguishing between CAS and CAD, ROC analysis was performed. A serum SIRT6 level of 546.384 pg/mL was identified as the optimal cutoff value for discriminating between CAS and CAD (AUROC 0.725, 95% CI 0.653 - 0.797) (Figure 2B).

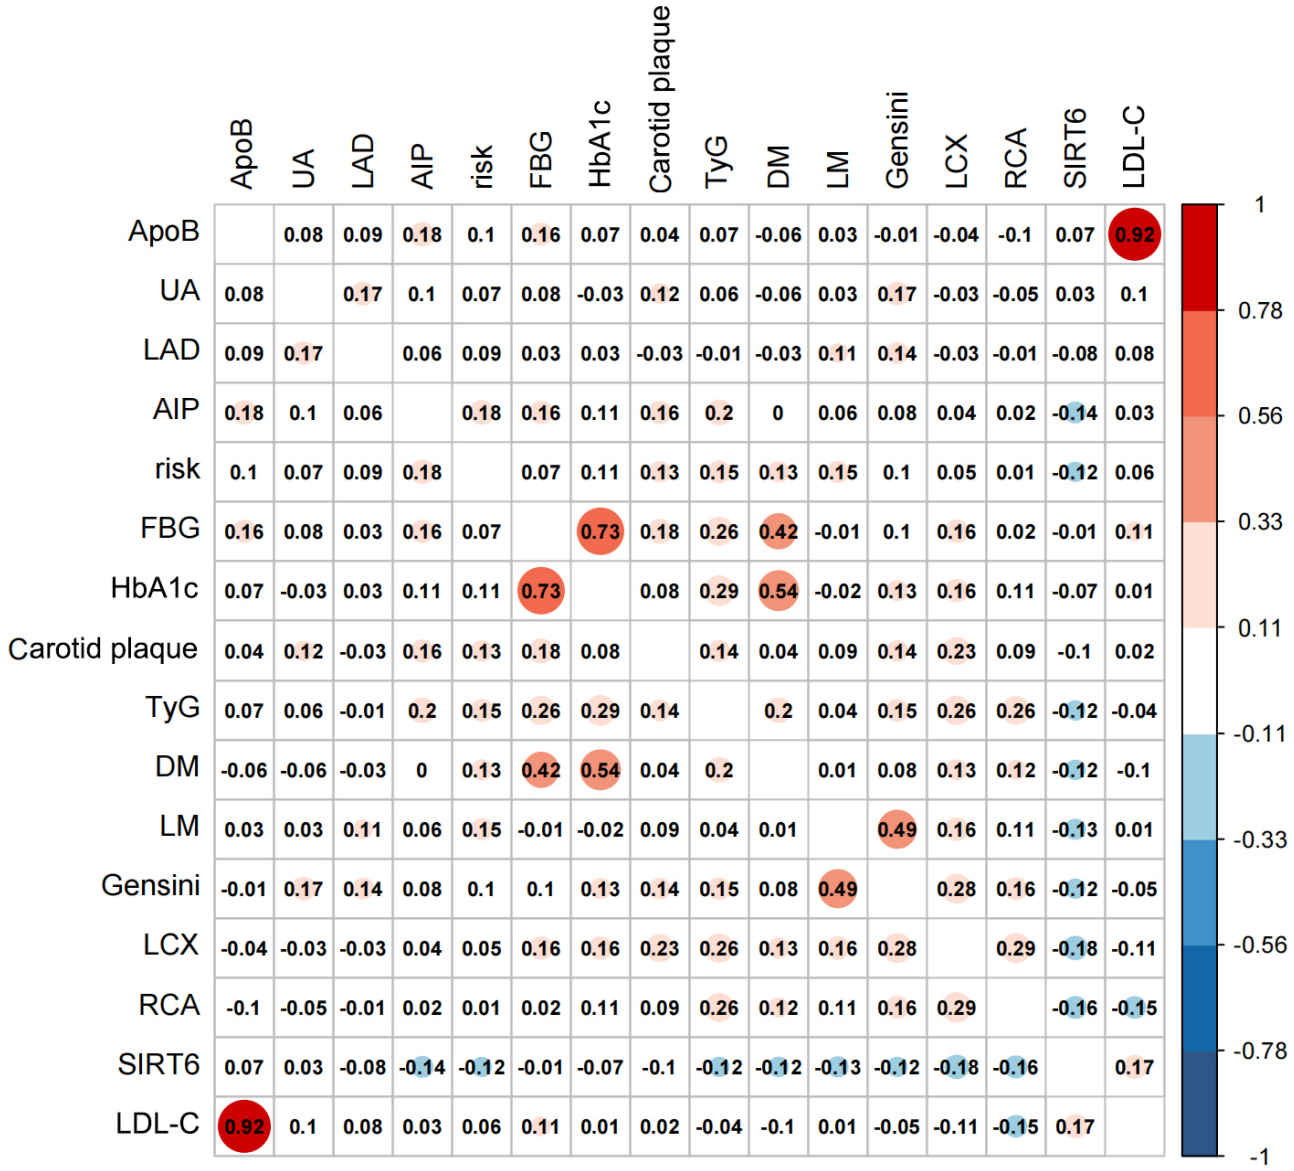
Figure 2. Serum levels of silent information regulator 6 (SIRT6) and receiver operating characteristic (ROC) curve. (**A**) Serum levels of SIRT6 were lower in patients with CAD and patients with CAS. (**B**) ROC curve analysis of SIRT6 in predicting the diagnosis of CAD (AUROC 0.725, 95% CI 0.653 - 0.797). AUROC: area under the receiver operating characteristic curve; CAD: coronary artery disease; CAS: coronary atherosclerosis.



Exploration of Variable Correlations

Factors with significant differences in intergroup analysis, including ApoB, unstable angina pectoris, LDL-C, AIP, FBG, HBA_{1c}, TyG index, history of diabetes mellitus, SIRT6, LAD, AIP, 10-year cardiovascular risk, carotid plaque burden, segmental vascular lesions, and Gensini score, were selected for further interfactor correlation analysis. To illustrate the correlations among these predictive indicators, a correlation coefficient matrix graph was constructed. While serum SIRT6 did not exhibit positive correlations with other indicators, aside from LDL-C, it demonstrated negative correlations with the Gensini score, 10-year cardiovascular risk, and carotid plaque burden (Figure 3).

Figure 3. Correlation heatmap analysis. AIP: atherogenic index of plasma; ApoB: apolipoprotein B; DM: diabetic mellites; FBG: fasting blood glucose; HbA_{1c}: hemoglobin A_{1c}; LAD: left anterior descending branch; LCX: left circumflex artery; LDL-C: low-density lipoprotein cholesterol; LM: left main coronary artery; RCA: right coronary artery; Risk: 10-year cardiovascular risk; SIRT6: silent information regulator 6; TyG: triglyceride glucose; UA: unstable angina pectoris.

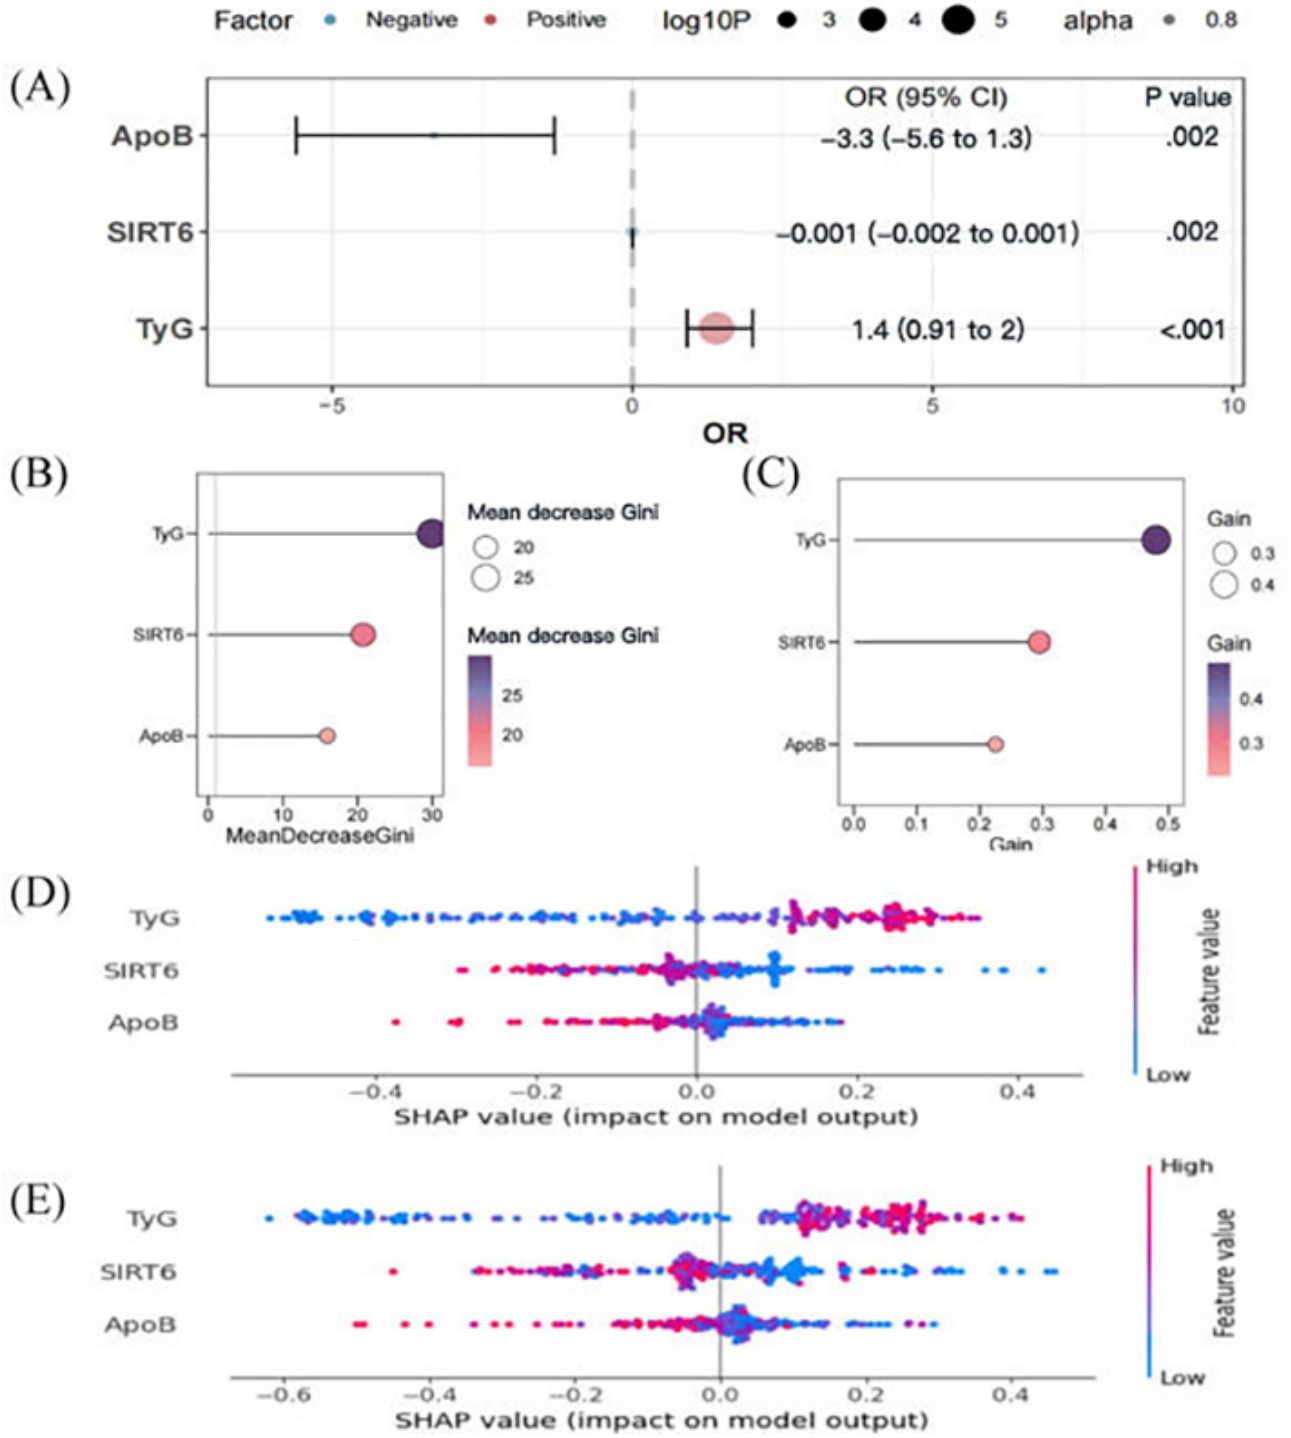


A correlation coefficient matrix graph was constructed. Darker shades represent stronger correlations, with positive correlations indicated by positive values and negative correlations by negative values. The predictive indicators included in this analysis are primarily independent predictive factors.

Feature Selection and Ranking

The significance of variables was preliminarily evaluated by LR analysis. Ultimately, serum SIRT6 levels, TyG index, and ApoB were incorporated into the model construction (Figure 4A). Feature importance ranking was determined using Gini (Figure 4B), Gain (Figure 4C), and Shapley Additive Explanation values (Figure 4D and E), which yielded similar results (Figure 4).

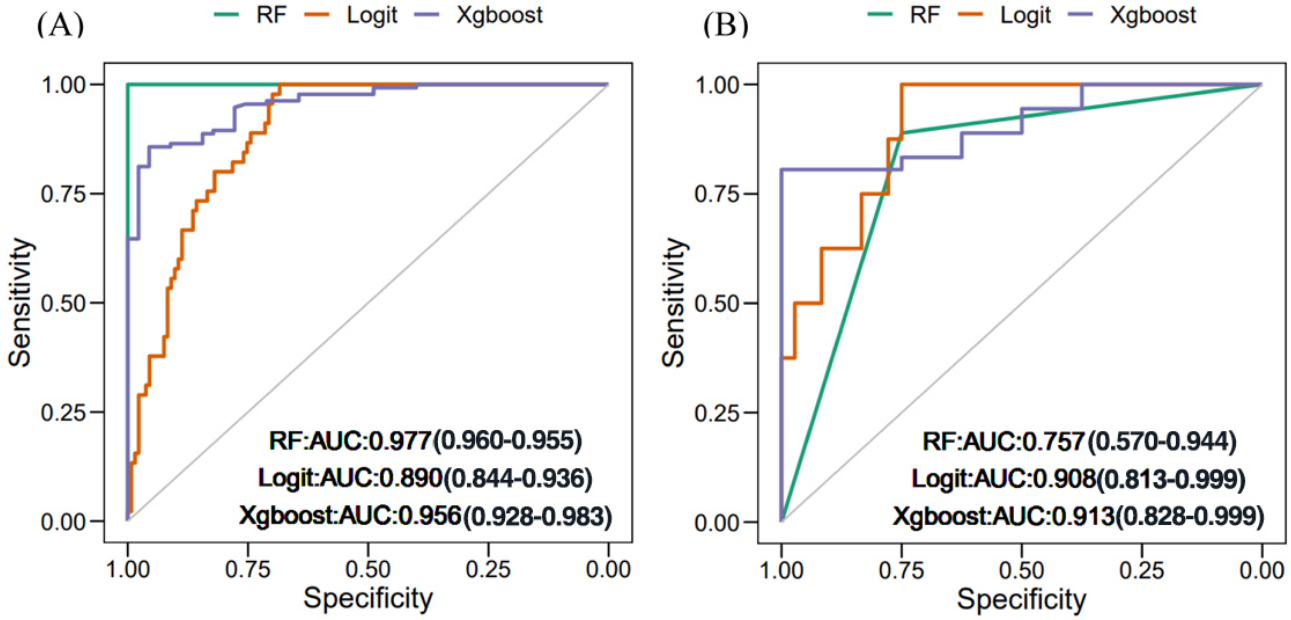
Figure 4. Feature importance. (**A**) Logistic regression results; (**B**) random forest results; (**C**) XGBoost results; (**D**) random forest SHAP; and (**E**) XGBoost SHAP. ApoB: apolipoprotein B; OR: odds ratio; SHAP: Shapley Additive Explanation; SIRT6: silent information regulator 6; TyG: triglyceride glucose; Extreme Gradient Boosting XGBoost.



Model Performance Comparisons

An LR model and 2 machine learning models were constructed to predict the development of CAD in older adult patients. The discriminative performance of the 3 models is shown via ROC curves in Figure 5.

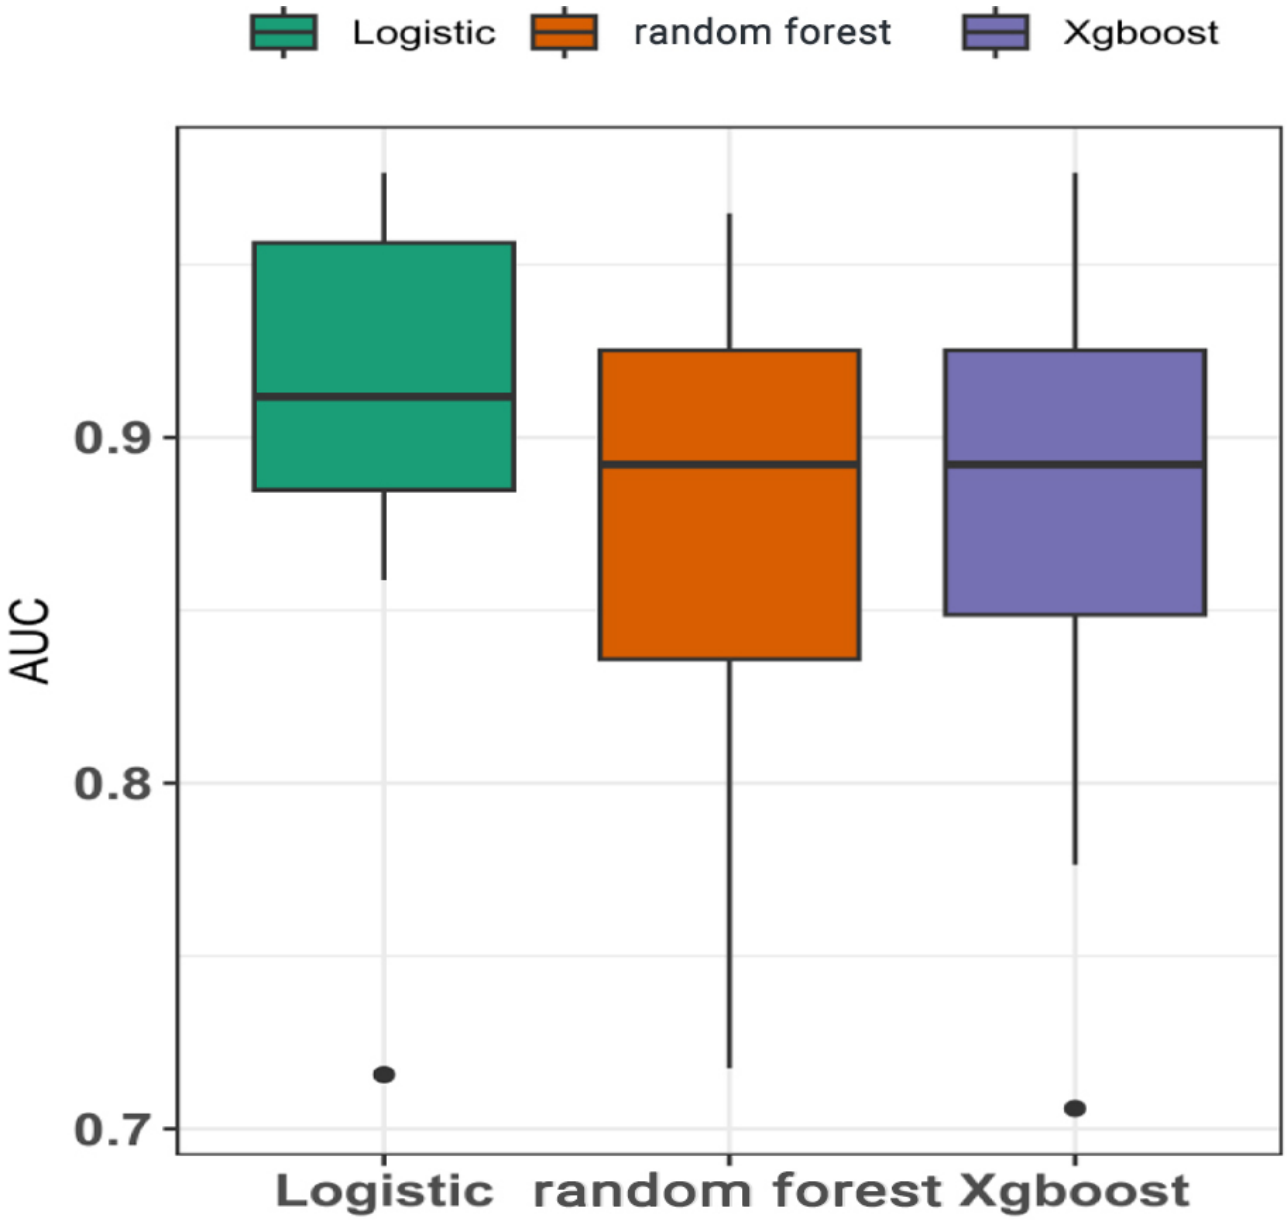
Figure 5. Receiver operating characteristic curves for predicting different classes using various models. (**A**) AUROC of the training set and (**B**) AUROC of the validation set. AUROC: area under the receiver operating characteristic curve; RF: random forest; Xgboost: Extreme Gradient Boosting.



In the training set, the random forest model demonstrated the best predictive ability for CAD in older adult patients (AUROC 0.977, 95% CI 0.960 - 0.995), followed by the XGBoost (AUROC 0.956) and LR (AUROC 0.890) models (Figure 5A). However, in the validation set, the classification performance of the random forest model was noticeably inferior to that of the XGBoost model. The AUROC values of XGBoost, LR, and random forest models were 0.913, 0.908, and 0.757, respectively (Figure 5B).

In cross-validation, the LR model demonstrated the best predictive ability for CAD in older adult patients (AUROC 0.912), followed by the XGBoost (AUROC 0.892) and random forest (AUROC 0.892) models (Figure 6).

Figure 6. Cross-validation AUROC of various models. AUROC: area under the receiver operating characteristic curve; Xgboost: Extreme Gradient Boosting.



Detailed performance metrics of the 3 models are shown in Table 2. The XGBoost model exhibited the best discrimination, with the highest recall (1) and accuracy (0.863), the second-highest precision (0.833), and the second-highest F_1-score (0.909). Although the XGBoost model may not perform as well as the other 2 models in certain aspects, its overall stability and balanced performance on both the training and the validation sets make it a more reliable choice. As a results, we developed a CAD prediction model for the older adults using the XGBoost algorithm and visualized the results through a nomogram. The nomogram based on the serum SIRT6-level model is shown in Figure 7.

Table . Model performance metrics.

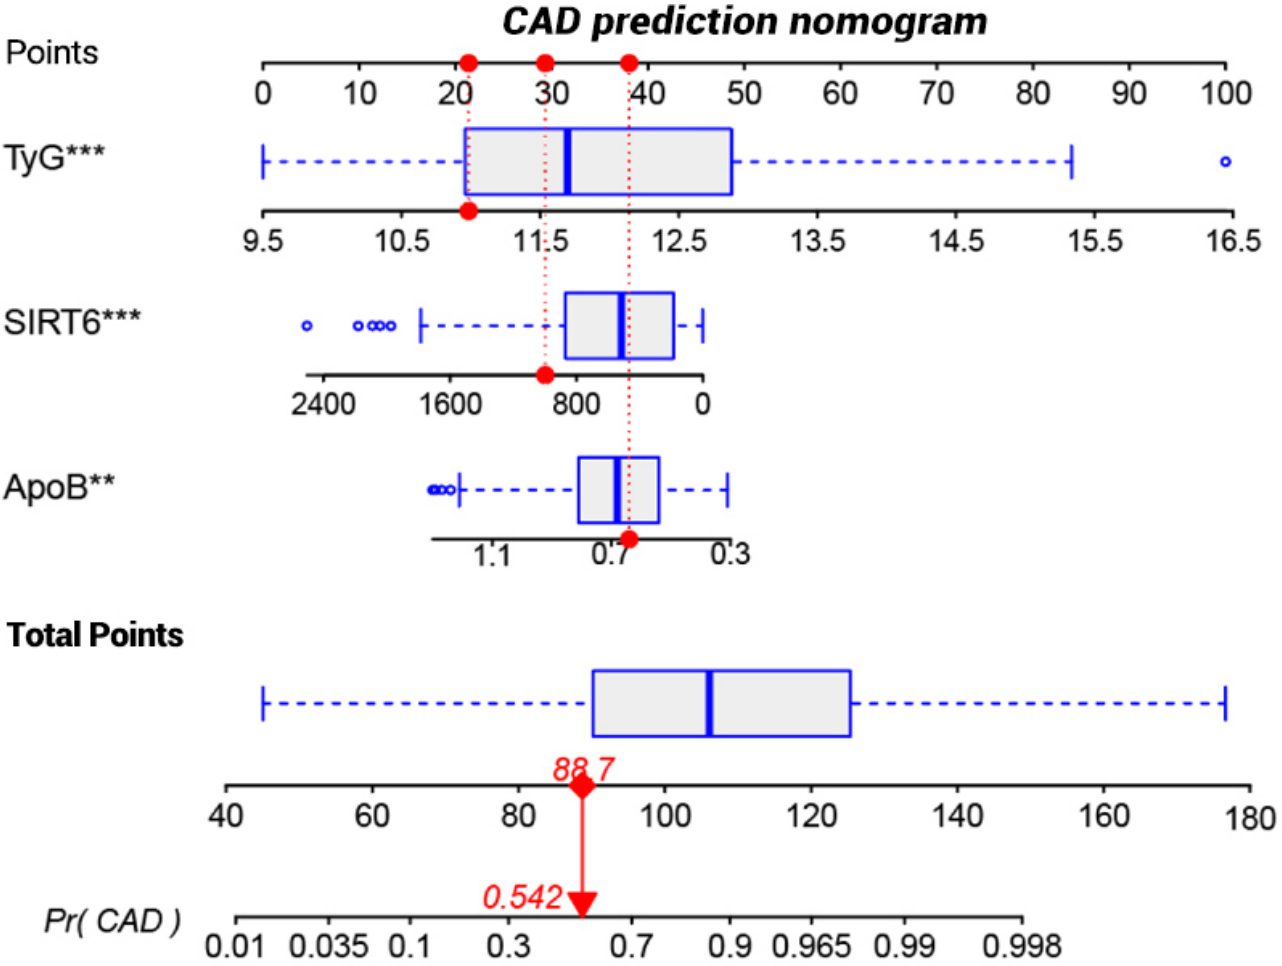
Model	Accuracy	Precision	Recall	F_1-score
LR[a]	0.795	0.75	1	0.857
RF[b]	0.863	0.941	0.889	0.914
XGBoost[c]	0.863	0.833	1	0.909

[a]LR: logistic regression.

[b]RF: random forest.

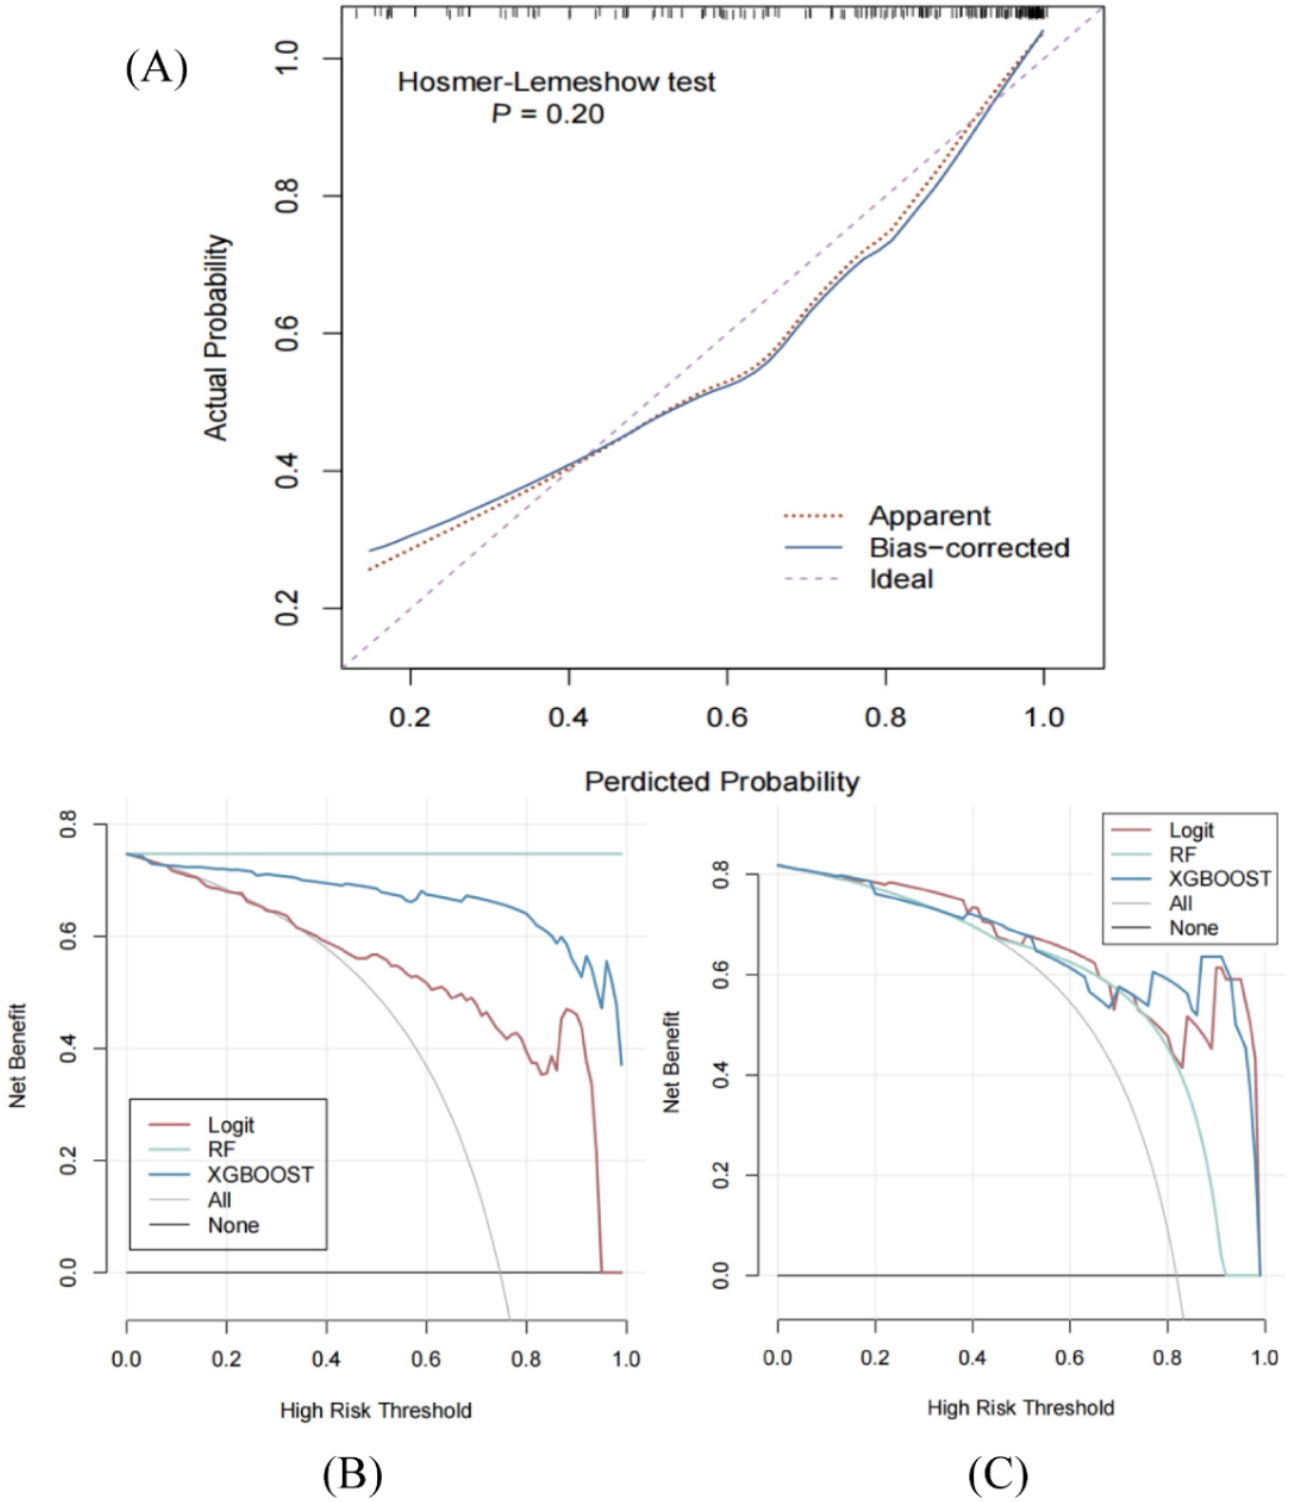
[c]XGBoost: Extreme Gradient Boosting.

Figure 7. Nomogram for predicting the probability of CAD. Variables of significance (**P≤.01 and ***P≤.001). ApoB: apolipoprotein B; CAD: coronary artery disease; SIRT6: silent information regulator 6; TyG: triglyceride glucose.



The calibration curves (Figure 8A) showed a similar trend among the 3 models, and the Hosmer-Lemeshow test results (χ^{28}=11.001; P=.20) indicated no significant difference between the predicted and observed values. These data suggest that the XGBoost model has good calibration ability.

Figure 8. Calibration curve and decision curve analyses for predicting coronary artery disease. (**A**) Calibration curves of the training cohort; (**B**) decision curve analysis (DCA) of the training cohort; and (**C**) DCA of the validation cohort. RF: random forest; XGBoost: Extreme Gradient Boosting.



The DCA revealed that the XGBoost model exhibited greater net benefit along with the threshold probability, indicating its superior clinical use compared with other models (Figure 8B and C).

Discussion

Principal Findings

An accurate risk assessment is critical for patient-centered clinical decision-making. The nomogram presented in this study may serve as an important clinical decision aid tool, assisting in determining whether invasive CAG should be performed, or informing patients as a basis for joint decision-making. In this study, traditional LR and 2 common machine learning

algorithms were used to establish a prediction and evaluation model of coronary artery stenosis in older adult patients with suspected CAD. Through a comprehensive analysis of models, the XGBoost algorithm–based model with excellent prediction performance and good internal verification ability was selected. In addition, we developed a nomogram for CAD prediction by combining traditional clinical variables (eg, ApoB) with 2 novel variables relevant to the older adult population, serum SIRT6 levels and the TyG index, which allowed for assessing the risk of coronary artery stenosis more conveniently and interactively (Figure 6). This, to some extent, helps address the issue of poor interpretability, which often hampers the implementation of machine learning models.

Given its significant role in genomic stability, DNA repair, and telomere function, SIRT6 has been considered to have therapeutic potential in aging and aging-related diseases. Moreover, SIRT6 plays a crucial role in the development and progression of CAD due to its involvement in oxidative stress, inflammation, and energy metabolism [20]. Previous studies have highlighted the importance of SIRT6 in protecting blood vessels and the heart from endothelial dysfunction, atherosclerosis, myocardial fibrosis, and ischemia or reperfusion injury [21,22].

In this study, we observed lower serum SIRT6 levels in older adult patients with CAD than in those with CAS. Correlation analysis revealed a negative association between serum SIRT6 levels and the Gensini score, suggesting that reduced serum SIRT6 levels may exacerbate the severity of coronary artery lesions. Furthermore, serum SIRT6 levels were negatively correlated with segmental vascular lesions and carotid plaque burden, indicating that serum SIRT6 may reflect the overall burden of atherosclerotic plaques in blood vessels. Dyslipidemia is an independent risk factor for the occurrence and development of CAD, while diabetes mellitus doubles the risk of cardiovascular disease and is a leading cause of mortality in patients with dyslipidemia [23,24].

LDL-C levels are considered a determinant of the absolute risk of major cardiovascular events [25]. Previous evidence has revealed that liver-specific knockout of SIRT6 significantly increases the proprotein convertase subtilisin/kexin type 9 (*PCSK9*) gene expression and plasma LDL-C levels, while SIRT6 overexpression improves lipid metabolism and reduces atherosclerosis risk by lowering plasma LDL-C and *PCSK9* levels [26]. Although a previous clinical study in a Chinese population of all ages found no correlation between serum SIRT6 and LDL-C levels [15], in this study, we found a positive correlation between serum SIRT6 and LDL-C levels. Future investigations are needed to explore the mechanisms by which SIRT6 affects cardiovascular function through lipid metabolism in the older adult population.

Disruption of glucose homeostasis is another recognized risk factor for CAD. Animal models have shown that SIRT6 plays an important role in glucose production and uptake, insulin signaling, and metabolism [27]. Our data revealed that circulating SIRT6 levels were negatively correlated with FBG and the comorbidity of diabetes, which is consistent with previous findings [28]. Whether glucose metabolism disruption mediates the relationship between SIRT6 and CAD warrants further investigation. In addition, our study identified serum SIRT6 as an independent biomarker for assessing the severity of coronary artery lesions in older adults, with the optimal cutoff value for classifying atherosclerosis and CAD being 546.384 pg/mL.

Abnormal blood lipids are established independent risk factors for CAD. Unlike previous studies that commonly included LDL-C, HDL-C, and other conventional measures, our study incorporated ApoB as one of the predictive factors. ApoB is a crucial component of LDL-C, and its deposition within the arterial wall is a fundamental step driving the progression of atherosclerosis, from initial lipid deposition to the development of acute complex events, such as plaque rupture [29]. Compared with other individual lipid markers, ApoB serves as a more accurate biomarker for cardiovascular risk assessment [30,31]. Elevated ApoB levels, representing LDL levels, are associated with the occurrence of CAD, and ApoB levels are positively correlated with the Gensini score, indicating the degree of atherosclerosis and arterial narrowing [32]. In addition, circulating ApoB levels are considered more predictive than plasma cholesterol levels for early-onset CAD risk [33]. Correlation analysis indicated a significant positive correlation between ApoB and LDL-C levels. Moreover, in all 3 statistical methods used for feature selection, ApoB consistently emerged as significant, which is in line with previous findings [31]. However, in an intergroup analysis, we observed higher levels of ApoB in the CAS group than in the CAD group, which is contrary to previous results [33].

Insulin resistance further disturbs glucose and lipid metabolism in patients with diabetes, promoting chronic inflammation, disrupting normal endothelial function, and accelerating the development of complications, such as atherosclerosis-related cardiovascular diseases. The persistent prevalence of insulin resistance is considered a major contributor to the high mortality rate in atherosclerosis-related cardiovascular diseases worldwide [34]. The TyG index is a quantitative measure based on blood glucose and triglycerides that assesses insulin resistance. A clinical study has shown an association between the TyG index and coronary artery calcification [35]. However, in cohort studies, the TyG index was found to be correlated with carotid atherosclerosis [36] but unrelated to the incidence of CAD [37]. In our study, intergroup analysis revealed that the TyG index was significantly higher in the CAD group than in the CAS group. Correlation analysis indicated positive associations between the TyG index and the Gensini score, carotid plaque burden, and segmental vascular lesions. Furthermore, in multifactorial regression analysis and machine learning feature selection, the TyG index consistently demonstrated a strong correlation with CAD, suggesting that it may be an independent risk factor for CAD. Furthermore, we observed a negative correlation between serum SIRT6 levels and the TyG index. Future research is needed to explore the impact of SIRT6 on the TyG index and to elucidate the relationship between these factors in terms of glucose and lipid metabolism disturbance and the development of CAD.

Strengths and Limitations

Our prediction model addresses the challenge of poor interpretability associated with machine learning models. By incorporating readily obtainable clinical and physiological indicators, this nomogram not only provides prediction results and probabilities directly but also facilitates personalized intervention through probability curves. Tailored patient treatment may reduce medical costs and unnecessary invasive tests. Particularly in resource-constrained medical settings, our model may assist in disease screening and alleviate the medical burden.

Although the overall performance of the model was good, the sample distribution in our study was not balanced, and the model was not validated externally with independent data sets. Therefore, the generalizability and extrapolation to the overall population cannot be currently estimated. Second, the model was more inclined to classify patients without the disease as having the disease, while the proportion of patients with the disease misclassified as being disease-free was very low. The rate of missed diagnosis was also low. Third, the limited small sample size and single-center, cross-sectional design constrained the generalizability of the results. Furthermore, this study specifically focused on the older adult population; however, there is currently no consensus on age-related changes in circulating ApoB levels. Furthermore, some studies have suggested that the ApoB–apolipoprotein A1 (ApoA1) ratio has a higher predictive value for atherosclerosis and intima-media thickness than individual lipid markers. Therefore, in future research, expanding the sample size and using the ApoB-ApoA1 ratio as a composite indicator are needed to further evaluate the correlation between ApoB and the severity of coronary artery lesions.

Conclusions

Based on the LR, random forest, and XGBoost algorithms, we developed a predictive model for CAD occurrence in the older adult population, incorporating SIRT6, the TyG index, and ApoB. The model was comprehensively evaluated for discrimination, calibration, clinical applicability, and internal validation. The XGBoost predictive model exhibited favorable predictive performance and clinical use, which may facilitate early CAD screening and diagnosis in older adult patients, particularly for identifying high-risk individuals. Furthermore, the model may reduce unnecessary invasive examinations in negative patients and minimize missed diagnoses in positive patients. The personalized probability curve generated by the model may offer targeted intervention guidance. Our findings also underscore the importance of considering risk factors such as SIRT6, ApoB, and TyG levels in this population.

Acknowledgments

This research is supported by a grant from the National Natural Science Foundation of China (grant 82103079) and the Shanghai Municipal Health Commission Clinical Research in Health Industry Project (grant 202140052).

Authors' Contributions

YY conceptualized and designed the study, collected and analyzed data, drafted the manuscript, and implemented the study. WL and YZ provided the study materials instrumentation and other analysis tools and checked literature. All authors had full access to all the data in the study and accepted responsibility to submit for publication. All authors revised the manuscript and approved the final manuscript as submitted.

Conflicts of Interest

None declared.

Abstract

Background: The prevalence of stroke is high in both males and females, and it rises with age. Stroke often leads to sensor and motor issues, such as hemiparesis affecting one side of the body. Poststroke patients require torso stabilization exercises, but maintaining proper posture can be challenging due to their condition.

Objective: Our goal was to develop the Postural SmartVest, an affordable wearable technology that leverages a smartphone's built-in accelerometer to monitor sagittal and frontal plane changes while providing visual, tactile, and auditory feedback to guide patients in achieving their best-at-the-time posture during rehabilitation.

Methods: To design the Postural SmartVest, we conducted brainstorming sessions, therapist interviews, gathered requirements, and developed the first prototype. We used this initial prototype in a feasibility study with individuals without hemiparesis (n=40, average age 28.4). They used the prototype during 1-hour seated sessions. Their feedback led to a second prototype, which we used in a pilot study with a poststroke patient. After adjustments and a kinematic assessment using the Vicon Gait Plug-in system, the third version became the Postural SmartVest. We assessed the Postural SmartVest in a within-subject experiment with poststroke patients (n=40, average age 57.1) and therapists (n=20, average age 31.3) during rehabilitation sessions. Participants engaged in daily activities, including walking and upper limb exercises, without and with app feedback.

Results: The Postural SmartVest comprises a modified off-the-shelf athletic lightweight compression tank top with a transparent pocket designed to hold a smartphone running a customizable Android app securely. This app continuously monitors sagittal and frontal plane changes using the built-in accelerometer sensor, providing multisensory feedback through audio, vibration, and color changes. Patients reported high ratings for weight, comfort, dimensions, effectiveness, ease of use, stability, durability, and ease of adjustment. Therapists noted a positive impact on rehabilitation sessions and expressed their willingness to recommend it. A 2-tailed t-test showed a significant difference (P<.001) between the number of the best-at-the-time posture positions patients could maintain in 2 stages, without feedback (mean 13.1, SD 7.12) and with feedback (mean 4.2, SD 3.97), demonstrating the effectiveness of the solution in improving posture awareness.

Conclusions: The Postural SmartVest aids therapists during poststroke rehabilitation sessions and assists patients in improving their posture during these sessions.

Introduction

The 2019 Global Burden of Disease report indicates that stroke is a major global health issue, with around 12.2 million new cases and 6.6 million deaths worldwide that year. This makes stroke the second leading cause of death and the third leading cause of disability [1], with its occurrence increasing with age and affecting both males and females [2]. In Brazil, stroke is the leading cause of death, and mortality from stroke has increased in recent years. Registering 103,000 deaths in 2019, the number rose to over 112,000 by 2023 [3].

One of the most common and challenging poststroke conditions is hemiparesis, which affects a substantial number of stroke survivors globally [4,5]. For these patients, controlling trunk movement becomes a fundamental motor skill essential for performing various functional tasks [6,7]. For instance, research shows that maintaining proper posture correlates with walking ability in patients undergoing acute stroke rehabilitation [8].

In individuals without hemiparesis, posture typically involves symmetric and balanced alignment of all body parts, including the head, shoulders, spine, hips, and limbs, following the body's natural curves. In contrast, a person with hemiparesis, characterized by muscle weakness on one side of the body due to brain injuries or stroke, may exhibit an asymmetric posture, resulting in an imbalanced or tilted position. We refer to the term "best-at-the-time posture" to describe the optimal posture achievable by a hemiparetic patient, considering their motor limitations (we use the term "correct posture" interchangeably). The goal is to achieve the highest level of alignment and balance possible.

The literature registers many efforts to support stroke survivors with respect to improving trunk stability [9], trunk compensation [10], motor control [11-13], and accessing mobility [14]. Furthermore, a systematic review has confirmed the significantly positive impact of trunk training on various aspects of trunk control, sitting and standing balance, and mobility [15].

In health care, literature acknowledges the promise of smartphones [14,16] and wearables [17-20] in empowering individuals, aiding diagnosis, promoting behavior change, and enabling self-monitoring. Wearable and rehabilitation devices for different body parts, such as head, limbs, and torso, enhance training outcomes through valuable feedback [21-24]. Moreover, numerous studies have affirmed the feasibility of inertial sensors for balance and gait assessment [25-28], as corroborated by comprehensive literature reviews [29,30], even for individuals with chronic stroke [31].

In the context of wearable technology for poststroke patient support, researchers have delved into various aspects. For instance, studies demonstrated the feasibility of using step activity monitors for patients with recent stroke [32,33]. One study involved the use of intelligent insoles for analyzing the gait of patients with hemiparesis [34]. Another result is a home-based rehabilitation system using wearable sensors in smartwatches, allowing therapists to monitor patients remotely [35]. In another study, the authors evaluated the impact of haptic nudging delivered via a wrist-worn wearable device on upper limb movement during inpatient stroke rehabilitation [36]. Additionally, a recent study reported a test for assessing kinematic parameters in chronic stroke survivors. This test used a standardized mobility assessment with a simple smartphone attached to the lumbar spine using an elastic band to measure participants' kinematics [14].

Existing literature explores a range of wearable and mobile device-based solutions for postural monitoring. In the context of hemiparesis, researchers have investigated the effects of rhythmic haptic cueing on spatial and temporal gait characteristics using haptic feedback [37]. In a broader context, Smart Pose leverages a smartphone's camera, accelerometer, and magnetometer to detect poor neck posture during smartphone use, providing feedback through vibrations, text messages, and alarms [38]. Additionally, a 3-axis accelerometer biofeedback system corrected neck posture during prolonged computer use and effectively reduced inappropriate neck angles [28]. Other innovations include elastic t-shirts with embedded sensors for posture feedback [39], wearable devices for spine posture monitoring [40], and posture differentiation systems [41].

However, it is essential to recognize that effective functional rehabilitation requires both body awareness and torso control to ensure upper limb functionality [4,7,9,42]. Additionally, concerns regarding the cost and availability of treatment [43-46] highlight the need to explore alternatives that use ubiquitous, low-cost smartphones. Despite the growing number of mHealth mobile apps for patients with stroke [47], few address trunk control as a primary focus [27,48,49]. Furthermore, while both intrinsic and extrinsic feedback are crucial for motor learning after stroke [50-52], and therapists spend a significant amount of time providing this feedback [53,54], few efforts used multisensory feedback from smartphones for upper body rehabilitation [24]. Moreover, while smartphone-based multisensory feedback has proven effective for postural monitoring in healthy individuals [55], similar solutions for patients with stroke are still lacking. This highlights the need for research into new wearable technologies to enhance rehabilitation support and improve posture and trunk awareness in patients with stroke.

To address this challenge, we aimed to develop Postural SmartVest. This affordable wearable technology takes advantage of low-cost smartphone resources by (1) leveraging the built-in accelerometer sensor to monitor sagittal and frontal plane changes continuously and (2) exploiting the device's visual, tactile, and auditory feedback to guide patients in performing the movements required to return to their best posture at the time.

Methods

Overview

The research group comprises 2 occupational therapists (authors APP and VMCE) and 2 computer scientists (authors OJMN and MDGCP). To design the initial software architecture, the group received input from other health and computing professionals [56].

The study was conducted in a specialized rehabilitation center that requires both ethical committee approval and verification of ethical and safety aspects for studies conducted on its premises. Therapists participating had at least 1 year of experience in stroke rehabilitation and received training on device use before working with patients. The smartphones used in the feasibility study were either from the research team, having been tested and shown to function properly, or were participants' own devices. To minimize malfunction risks, no smartphone was allowed to be charged during use by participants. The Informed Consent Form informed participants about potential discomfort due to heat and the vest and assured them that, in the unlikely event of a smartphone malfunction causing an explosion, immediate assistance and emergency services would be provided. Data acquisition and storage were handled securely, with all data kept anonymized and stored in accounts requiring login via a secure network. Photographs were authorized with face identification removed. Participants consented to the use of data for the study and were informed of their right to withdraw at any time without coercion or obligation. Participation was voluntary and did not include any financial benefit, in compliance with Brazilian regulations.

The study comprised design and development iterations involving brainstorming meetings, interviews with therapists and patients, prototype development, feasibility studies, and experimental sessions (see workflow in Textbox 1).

Textbox 1. Research workflow.

Literature review

Iteration 1

- Brainstorm meetings
- Interview with therapists
- Prototype #1
- Feasibility study

Iteration 2

- Prototype #2
- Pilot study

Iteration 3

- Prototype #3
- Kinematic assessment
- Postural SmartVest

Within-subjects study

- Presession interviews with patients
- Experimental session
- Postsession interviews with patients
- Postsession interviews with therapists

Throughout the study, our literature review was ongoing and dynamically aligned with emerging themes. Initially, it concentrated on the specific needs of patients with stroke [4] and the effectiveness of trunk training [15]. Next, we reviewed work on novel wearable [21] and affordable smartphone-based solutions [31], including reports in literature reviews [29,57], and noticed the involvement of healthy adults in feasibility studies [26,58], as well as control participants [27]. These works are representative of the broader ongoing review process, which continued to cover these and additional relevant areas throughout the study.

We used the Google Sheets software for statistical analysis relative to the within-subject study. We used thematic analysis [59] for categorizing interview responses. For the kinematic assessment, we compared angular momentum from values calculated by Vicon and the smartphone’s sensors.

Participants

Our study involved 3 groups: poststroke participants, therapists, and healthy participants. We used interviews and questionnaires to collect requirements, demographic data, and their impressions of Postural SmartVest.

For the interviews with therapists, the inclusion criterion was having at least 1 year of experience in stroke rehabilitation. We invited professionals from a rehabilitation center using printed flyers and email invitations. In the feasibility study, we recruited participants via university email: the inclusion criteria were being 18 years or older and owning a smartphone. The exclusion criterion was self-reported physical or cognitive impairments. For the pilot and within-subjects studies, the inclusion criteria were having chronic hemiparesis, being 18 years or older, walking independently, having cognitive ability for communication, and attending rehabilitation sessions at least twice a week for a minimum of 1 month.

Iteration 1: Brainstorming Meetings, Interviews With Therapists, and Feasibility Study

For the brainstorming meetings, the research team held three 2-hour sessions to gather functional and nonfunctional requirements for the solution to develop the initial prototype comprising the vest and the app, Prototype #1 (Figure 1).

For the interviews with therapists, one team member (APP) conducted semi-structured interviews with therapists. The interview adhered to a structured protocol comprising 8 questions categorized into 4 categories: resources for posture improvement, general technology acceptance, specific technology requirements, and smartphone use (Multimedia Appendix 1: App A).

Figure 1. Prototype #1 in use in the deployment phase of the feasibility study.

For the feasibility study, we used the first version of the app. We created 8 vests and conducted sessions with 8 participants at a time. We provided smartphones to participants who could not use their own. Each session lasted 2 hours and followed a 3-phase protocol: preparation, deployment, and follow-up. In the preparation phase, therapists adjusted the vests and calibrated the seating posture for each participant.

In the deployment phase, participants set their devices to airplane mode and wore headphones to ensure privacy for their feedback. They then engaged in smartphone-free activities like reading or using their laptops (Figure 1). The deployment phase consisted of two 30-minute segments: feedback from the app was turned off during the first part and turned on during the second. The app continuously recorded the participants' postural data throughout both segments in this phase.

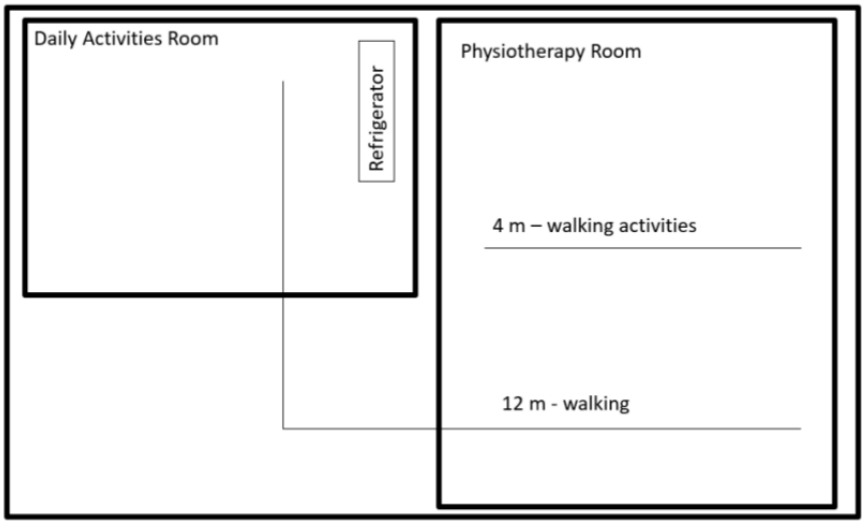
In the follow-up phase, participants responded to 2 questionnaires, one with scaled questions and the other with open-ended inquiries. These questionnaires aimed to assess usability and satisfaction. One questionnaire evaluated Postural SmartVest as an assistive technology for posture correction (Multimedia Appendix 1: App B), while the second assessed Postural SmartVest as an assistive technology in general (Multimedia Appendix 1: App C). For the latter questionnaire, we adapted the Quebec User Evaluation of Satisfaction with Assistive Technology (QUEST; version 2.0), a 12-item assessment designed to measure user satisfaction with devices and services [60]. We used a translated and validated version [61] and focused on the device-related section of the questionnaire. This section included 8 scale questions that assessed size, weight, adjustability, safety, durability, ease of use, comfort, and overall effectiveness of the technology.

Iteration 2: Pilot Study

The feedback from the previous iteration guided the design of Prototype #2. We then used this prototype in a pilot study involving 1 patient with hemiparesis to observe the solution and detail the within-subjects study design. In the pilot study and the following studies, the smartphone used was a Motorola G with Android (version 5.1).

During the pilot study, the poststroke patient followed a protocol that included 5 ambulant-based daily activities conducted in the therapy room (Figure 2). The protocol consisted of 4 distinct phases. In the first phase, the participant walked 8 m, incorporating forward, sideways, and backward walking. In the second phase, they proceeded with a 12-m free walk to a refrigerator. In the third phase, the participant engaged in an upper limb activity that entailed opening the refrigerator, taking a glass, and returning it to the fridge. Finally, in the fourth phase, they completed a 12-m free walk back to the starting point.

Figure 2. Layout of the therapy room.



Iteration 3: Kinematic Assessment

The feedback from the pilot study informed the development of a new prototype (Prototype #3). At this stage, we checked the accelerometer readings obtained by the app running on Motorola G with Android (version 5.1).

On the one hand, sensor type and placement, activity characteristics, and population-specific conditions can influence the accuracy of sensor outcome estimates, as reported in a study that used research-grade wearable sensors on the upper arms, waist, and ankles and included poststroke patients [62]. On the other hand, the literature reports positive results regarding using state-of-the-art smartphone accelerometer technology. For instance, researchers investigated the comparative performance of 3 different commercially available smartphone accelerometers among themselves and to a gold-standard Vicon MX motion capture system, indicating that the devices are valid and reliable measuring instruments for estimating linear accelerations [63].

We assessed the angle calculations of the third prototype by comparing them with the Vicon Gait Plug-in system, a gold-standard in full-body kinematic and kinetic modeling. The Vicon system includes software and fixed cameras that capture signals from a moving target, providing visual feedback through animated vectors and plans, and it also calculates quantitative data, including distances and angles between selected planes.

Under the guidance of one occupational therapist (APP), author OJMN used the prototype to perform 6 movements: trunk flexion, trunk extension, left and right-side bending, and left and right trunk rotation (Figure 3).

The therapist calibrated the subject's optimal posture position, and for all movements, the subject began in an upright position, executed the movement, and returned to the initial position. The Vicon system and the app prototype collected data simultaneously, following an initial manual synchronization process, with the Vicon recording frames at 250 frames per second and the app prototype recording angular moments at each second along with coordinate values. To reconstruct the trunk segment, we placed markers on the clavicle, sternum, cervical vertebra C7, thoracic vertebra T10, and a point located on the medial border of the right scapula. We conducted 6 sessions using 39 markers on a full-body model (Figure 4).

Following the kinematic assessment, Prototype #3 was referred to as SmartVest and was used for the remainder of the study (Figure 5).

Figure 3. Movements used for simultaneous data collection by Vicon and the app.

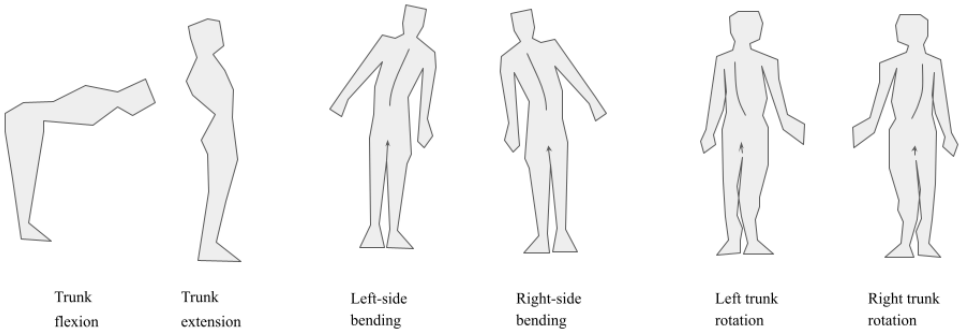


Figure 4. Simultaneous data collection by Vicon and the app.

Figure 5. The Postural SmartVest solution comprises a customizable smartphone app placed in a transparent pocket on an athletic, lightweight compression tank top.

Within-Subjects Study

The within-subjects study included individual sessions with poststroke patients, each accompanied by their therapists. Before that, therapists used the Postural SmartVest for about 30 minutes while the researchers provided guidelines to ensure the professionals understood how the solution worked. Only afterward did the therapists apply Postural SmartVest to their patients during their rehabilitation sessions. All sessions used the same smartphone (Motorola G with Android; version 5.1).

In the presession interview with each patient, we gathered information about their posture control during activities, awareness of posture issues, and any potential biases toward one side of the body. We also inquired about their strategies to correct posture problems when they noticed them (Multimedia Appendix 1: App D).

At the beginning of each session, the therapist adjusted the vest on the patient, calibrated the app to recognize the patient's best-at-the-time standing posture, and initiated the monitoring process (Textbox 2). Subsequently, the patient performed the activities defined in our pilot study twice, in consecutive sessions, each with an estimated duration of 10 minutes (Figures 6 and 7). The app did not provide feedback in the first session but registered all the movements. In the subsequent session, the app provided feedback through screen color changes (green and red), vibrations, and audio guidance.

Afterward, we asked the poststroke patients to fill out 2 questionnaires, one focusing on Postural SmartVest as an assistive technology for posture correction (Multimedia Appendix 1: App B) and the other assessing Postural SmartVest as a general assistive technology (Multimedia Appendix 1: App C).

Additionally, the therapists shared their feedback after working with the patients using a tailored version of the Postural SmartVest QUEST (version 2.0) questionnaire (Multimedia Appendix 1: App E). This study helped us understand the effectiveness of Postural SmartVest during stroke rehabilitation, both from the patient's and therapist's perspectives.

Textbox 2. Calibration workflow.

Adjust the vest on patient

Start the app

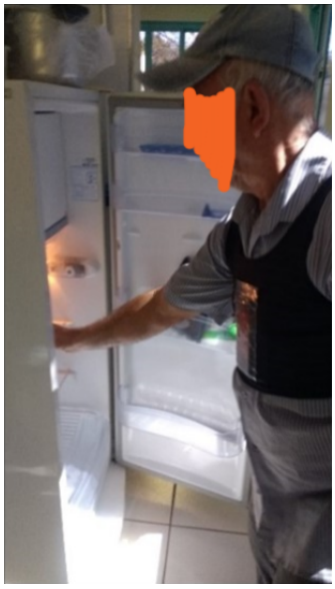
Access settings

- Enter the tolerance threshold angle for frontal movement (in degrees)
- Enter the tolerance threshold angle for lateral movement (in degrees)
- Enter the allowable duration for temporary deviations from the calibrated posture (in seconds)
- Ensure the option for vibration feedback is selected
- Ensure the option for audio feedback is selected
- Guide the patient to assume his best posture at that moment
- Press the "Calibrate" button to configure the current position as the best posture for monitoring
- Return to main screen

Press play or pause to initiate monitoring

Figure 6. Walking activity.

Figure 7. Upper limb activity.



Ethics Approval

The study received prior approval from the Hospital of the Clinics of the Ribeirão Preto School of Medicine at the University of São Paulo, Brazil, identifier 57234816.3.0000.5440. As detailed in the text approved by the ethics committee, the study adhered to ethical principles by ensuring beneficence through rigorous monitoring and support for participants, justice by offering equitable access and fair treatment, and respect by obtaining informed consent and addressing potential discomfort and safety concerns proactively.

Results

Participants

For the interviews, we enlisted 20 therapists: 10 occupational therapists and 10 physiotherapists. All participants were female, aged 26-40, with varying years since graduation (Table 1).

For the feasibility study, we recruited 28 healthy participants, aged 20-62, with an average age of 30.9. The group included 17 males and 11 females (Table 1). Of the participants, 25 used their own smartphones, while 3 used devices provided by us. The study covered 22 different smartphone models and 7 versions of the Android operating system.

For the pilot and within-subjects studies, we recruited poststroke participants from patients attending rehabilitation sessions at least twice a week for a month at the exact center. Inclusion criteria included chronic hemiparesis from stroke, aged 18 years or older, independent walking ability, cognitive ability for communication, and participation in rehabilitation sessions for at least a month.

We enrolled 1 patient for the pilot study and 40 patients for the within-subjects study (27 males, 67.5%), with a mean age of 57.1 (SD 11.42) years, and functional independence categorized as independent (n=39) of moderate assistance (n=1) on the functional independence measure [64,65]. Among them, 24 had right hemispheric lesions, 16 had left hemispheric lesions, and 38 had ischemic strokes. The duration of their condition ranged from 6 months to 19 years, with a majority between 1 and 4 years (Table 1).

Table 1. Participants' demographics.

Iterative Design

The Postural SmartVest solution comprises a customizable smartphone app for Android devices securely placed in a transparent pocket on an athletic, lightweight compression tank top (Figure 5).

Vest Component Evolution

The development of the vest component went through several iterations (Figure 8), with 6 prototypes created based on therapist's input (see responses in Multimedia Appendix 1: App F-G) and feedback gathered during the feasibility study (see responses in the Multimedia Appendix 1: App H). The final version of the garment used in the Postural SmartVest uses an off-the-shelf lightweight compression tank top made from polyamide with elastane. We added a perforated plastic pocket to the top front. The pocket serves 3 primary purposes: securely holding the smartphone, allowing for easy headset connection, and facilitating heat dissipation.

Figure 8. Vest prototypes developed during the iterative design.

App Component Evolution

The smartphone app also underwent significant changes during the iterative design process. Initially conceptualized following brainstorming sessions that defined both functional and nonfunctional requirements (Textbox 3 and Multimedia Appendix 1: App F), the app's preliminary software architecture was informed by input from health and computing professionals [56].

Overall, the app was guided by simplicity, feasibility, and adaptability principles, in line with cost-effective assistive technology solutions from our previous research [66]. Refinements and improvements were made based on therapist interviews and feedback obtained during the feasibility study

(Textbox 4). The final version has a main screen and a sliding panel for configuration options (Figure 9).

The app records every activity along with its corresponding timestamp. This record encompasses posture changes, feedback delivery, and adjustments to application settings. During the design, we evolved the app to use schemes suggested by the OpenMHealth organization [67] when saving log data.

Textbox 3. App requirements summary.

Functional requirements

- Therapist can calibrate best-at-the-time posture with 1 touch.
- Therapist defines threshold values for small movements.
- Therapist defines threshold values to indicate how long the patient can be off best-at-the-time posture before the app starts guiding the patient.
- The app guides the patient back to their calibrated best-at-the-time posture using screen color, vibration, and audio messages.
- The app must record and store all interactions for later export and analysis.

Nonfunctional requirements

- The app should work on a low-end smartphone.
- The smartphone should be attached to a vest within a transparent pocket.
- The app should be compatible with Android, the most common operating system in Brazil.
- The app should work with the screen off to conserve battery if needed.

Textbox 4. App development iterations

Prototype #1:

- Implements all functional and nonfunctional requirements
- Features a single screen displaying x, y, and z coordinates, directions, settings, and a calibration button
- Calibration settings are not stored for future use
- Provides 5 guiding messages in Brazilian Portuguese (1 for each direction and 1 for achieving the best-at-the-time posture)

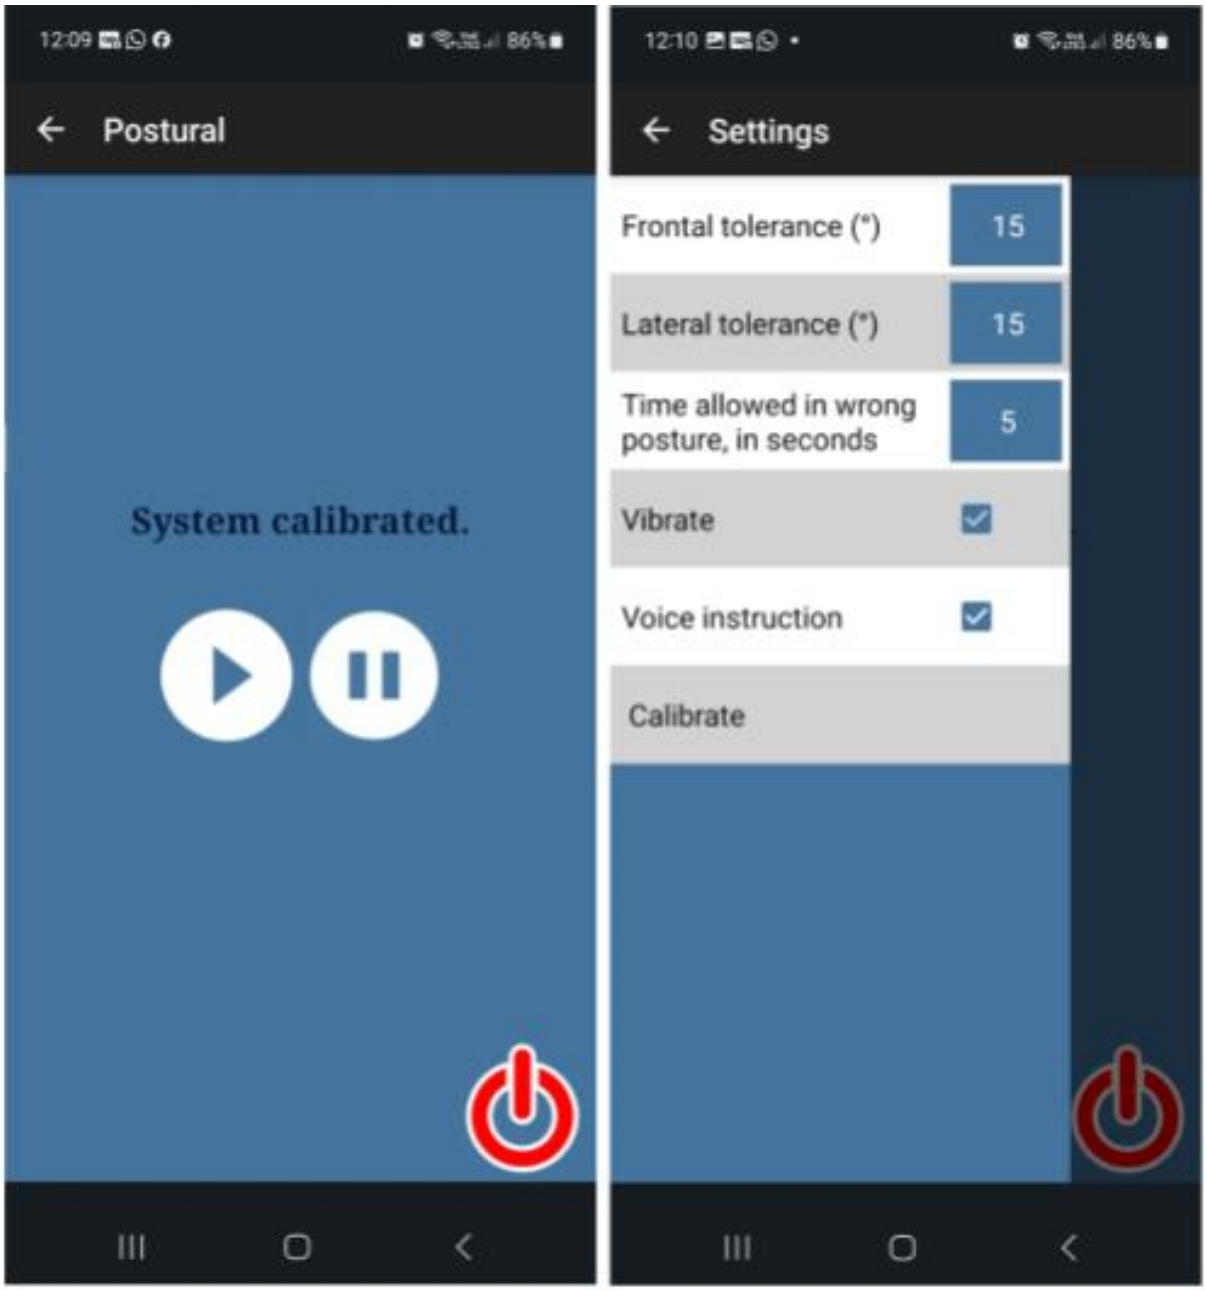
Prototype #2:

- Replaces coordinates and directions with information on sagittal and frontal planes, using values in degrees
- Introduces a new configuration screen for settings and calibration
- Stores and uses calibration settings until a new calibration is performed
- Stores all coordinate readings and feedback provided (version for kinematic assessment)
- Includes play and pause buttons for monitoring, along with an exit button on the home screen
- Expands the number of audio instructions, available in both English and Spanish
- Offers audio feedback every 5 minutes of maintaining the best-at-the-time posture

Prototype #3:

- Information on planes renamed to frontal and lateral planes
- Includes a help option with instructions on how to use the app

Figure 9. App main screen (left) and configuration panel (right).



App Component Interface

The app's main screen provides large buttons for easy access to pausing, resuming, and closing the application (Figure 9, left side). By clicking on "Postural" in the top bar on the left side of Figure 9, therapists can access 6 customization settings, as shown on the figure's right side. From top to bottom in the figure, the first 5 customization parameters allow therapists to configure thresholds for frontal and lateral movements (in degrees), to define the allowable duration for temporary deviations from the calibrated posture (in seconds), and to personalize feedback to the patient, including options for vibration and voice instructions. The therapist uses the last option, Calibrate, to set the best-at-the-time posture that the patient with hemiparesis can achieve at that moment. When calibration is activated, the app registers the current coordinates as the target posture for the patient to achieve and provides audio feedback.

After calibrating, the therapist can return to the main screen using the arrow in the top bar. From that point onward, the therapist can use the play and pause buttons to activate or deactivate posture monitoring. Additionally, we have included a large "off" button to allow the therapist to exit the application easily.

Monitoring starts when the therapist hits the play button, and the whole screen changes to green. If a patient's posture deviation exceeded the predefined thresholds for lateral and frontal angles relative to the calibrated posture, the app responded immediately with visual feedback, transitioning the screen color from green to red, and tactile feedback through vibrations. Furthermore, the app introduced audio feedback if a patient deviated from the best-at-the-time posture beyond the

allowed time for temporary deviations from the calibrated posture. Additionally, the app gives positive feedback every 5 minutes if the patient is maintaining the best-at-the-time posture. This comprehensive feedback system provided patients with real-time guidance tailored to their unique needs and specific postural challenges.

The app provides audio instructions: “please lean forward,” “please lean backward,” “please lean to the right,” and “please lean to the left.” We implemented enhancements throughout the iterations, such as adding positive feedback messages to encourage users to maintain the best-at-the-time posture and random variations in the messages that congratulate users for returning to their best-at-the-time posture.

To meet a requirement identified during the feasibility study, where participants used devices set to various languages, we improved the app to support users in English, Spanish, and Portuguese. It dynamically adapts its interface and voice instructions based on the language settings of the user’s device.

Kinematic Assessment

The kinematic assessment results, which involved comparing angular momentum values calculated by the Vicon system with those obtained from the smartphone's sensors, are presented graphically in the Multimedia Appendix 1: App I. The results consistently demonstrated that smartphone accelerometers offer reliable data readings, and our mobile application accurately interprets these values. These outcomes align with existing literature [24,28,38,40,58], reinforcing the utility of our approach within the context of our application. Moreover, this positive evaluation of the system's trustworthiness is in line with the feedback received from therapists regarding its performance and reliability, as detailed in the section *Postsession Interviews With Therapists*.

Pilot Study

The pilot study confirmed the proposed activity protocol for the within-subjects study, with participants safely completing the walking circuit within the estimated time frame.

Within-Subjects Study

Presession Interviews With Patients

Findings are summarized in Table 2. Out of the 40 participants with hemiparesis, 34 (85%) acknowledged experiencing challenges in balancing one side of their body. These participants reported various triggers for posture correction, including pain, the sensation of weight, and fatigue. Specifically, 6 participants stated that they only adjusted their posture when they felt pain, 3 did so in response to a sense of heaviness on the side affected by hemiparesis, and 2 did it to alleviate fatigue. Participants mentioned that they recognized the need for correction only when viewing photos (2 participants), standing in front of a mirror (2 participants), or following verbal advice from a family member (6 participants). In total, 4 participants admitted that they often neglected to correct their posture due to forgetfulness, with one of them explaining, “It is hard to remember, and correcting myself all day is tiring.”

When providing opinions on assistive technologies, participants considered the technologies “viable for use” and noted that they provide “progress to believe in improvement.” They also mentioned that these technologies “make rehabilitation more precise” and “help more than just me and the therapist.” Additionally, it was observed that they “stimulate people's lives even with minimal gain.” The repetition of these responses highlights the consistent perception of the technologies' value and potential impact.

Regarding the necessary requirements for the technology, 11 participants agreed that it could assist in the perception and control of the trunk. They envisioned the technology as a “chair that helps maintain correct posture” or “something that allows for posture visualization.” Some participants suggested a device that “corrects the arm and leg to prevent them from falling” and another that “reminds me to correct my posture.” They also proposed features such as “notifying to stay straight” or having the ability to “pull to the side.” Other suggestions included a “vest to correct posture” or a device that “attaches to the trunk and holds it in place.” Additional requirements included providing a “signal on the body,” “holding the shoulders, reminding to keep the back straight, and being fixed on the bra,” and being “close to the body,” “comfortable, practical, and unobtrusive,” and “adaptable to the body.” Participants emphasized that the technology should be “integrated with therapy,” “usable over time,” and “inexpensive.”

Table 2. Patients' report on posture, assistive technology, and smartphone usage.

Category	Patients, n
Maintenance of correct posture	
Unable to maintain posture	22
Able to maintain posture	17
Able to maintain posture sitting, but not standing	1
Perception of correct posture	
Perceive correct posture	36
Do not perceive correct posture	4
Difficulties and postural correction	
Remembering to correct and trying to adjust	8
Unable to correct posture	6
Need to leave sitting posture to correct	1
Triggers for posture correction	
After perceiving pain	6
After request from family	6
After perceiving weight on the side of hemiparesis	2
After feeling tired	2
After observing photos	2
After seeing oneself in the mirror	2
Opinion on assistive technology	
Believe it can help but consider it expensive	13
Knowledge from TV but no contact	2
Should be offered by the public health system	1
Would be good if recommended by professionals	1
Smartphone usage	
Participants with smartphones	26
Made accessibility adjustments	6
Experience difficulties	9
Use daily	19
Use sporadically	2
Use only for calls	4
Use only for WhatsApp, music, and camera	1
Other uses (WhatsApp, Facebook, YouTube, and internet banking)	12

Session Data

The average duration of the stages with and without feedback was 9.14 (SD 5.36) minutes and 8.52 (SD 3.21) minutes, respectively. A 2-tailed *t*-test indicated that these differences were not statistically significant.

We compared the number of the best-at-the-time posture positions patients could maintain in the 2 stages: without feedback and with feedback. The 2-tailed *t*-test results indicated a statistically significant difference between these 2 conditions. Specifically, in the stage with feedback, patients exhibited a higher ability to maintain correct positions (mean 13.1, SD 7.12) compared to the stage without feedback (mean 4.2, SD 3.97). This significant difference ($P<.001$) underscores that patients could achieve and sustain their best-at-the-time postures more frequently when Postural SmartVest provided feedback.

Additionally, we examined the average number of movements performed by patients to attain their best-at-the-time posture in both the stages without feedback and with feedback. In the stage without feedback, patients averaged 8.09 (SD 6.88) movements. In contrast, in the stage with feedback, they averaged 4.49 (SD 1.49) movements. The 2-tailed *t*-test results indicated no statistically significant difference between the values obtained in these 2 stages, with a *P* value of .11.

Postsession Interviews With Poststroke Patients

In the evaluation of satisfaction with Postural SmartVest, 37 (92.5%) patients reported being satisfied or very satisfied with the support provided by Postural SmartVest to help them maintain proper posture. In total, 2 respondents had neutral feelings, and 1 expressed dissatisfaction with the solution. In total, 39 (97.5%) patients said they would recommend the solution to others with hemiparesis due to stroke, and one indicated that they might recommend it.

When asked if they were able to maintain their correct posture, 17 patients answered “yes,” 2 responded with “sometimes,” and 21 answered “no.” When asked if they noticed that their body often tilted to a particular side, 18 reported that their body tilted to the right side, 16 indicated that their body tilted to the left, 3 stated that their body tilted backward, and 3 could not respond.

Responses to the questionnaire evaluating Postural SmartVest as an assistive technology using a 1-5 scale (Multimedia Appendix 1: App E) are summarized in Table 3. Regarding open-ended questions directed to the patients, we highlight in Table 4 some critical opinions and the number of users who expressed them.

Poststroke patients provided rich feedback on Postural SmartVest’s usability and effectiveness (Table 4). They suggested design improvements, such as incorporating openings with zippers and using breathable materials for cell phone accommodation. Some recommended extended usage periods, while others emphasized early implementation for gradual posture improvement. Software suggestions included customizable message frequency and varied vibration patterns. Participants highlighted the positive impact of audio feedback, likening it to therapist interactions during sessions. These insights, shared by a significant portion of the 40 patients, showcase the multifaceted utility of Postural SmartVest and its potential to address various poststroke rehabilitation needs. The integration of smartphones into thoracic clothing proved safe during our study, with no observed risks during continuous 1-hour use.

Table 3. Patients’ evaluation of postural SmartVest as an assistive technology.

Aspect	Favorable responses, %
Weight	100
Comfort	100
Dimension	97.5
Effectiveness	97.5
Ease of Use	87.5
Stability	82.5
Durability	72.5
Ease of Adjustment	67.5

Table 4. Patients’ responses to open-ended questions. The last column indicates the number of participants reporting.

	Responses, n
“I would suggest improvements to the garment, such as an opening Velcro or zipper and the use of breathable material to accommodate the cell phone.”	10
“The vest should be more discreet so that it could be worn more imperceptibly under the shirt.”	10
“The garment should be worn for a longer period, over one hour.”	4
“The solution should be introduced to me as early as the first rehabilitation session, immediately after a stroke, so I could get used to perceiving and correcting my posture earlier.”	4
“I would like to adjust the audio volume of the messages through the app.”	3
“The frequency of the messages should be customizable.”	3
“I would like different vibration patterns for different body movements.”	3
“Listening to the app's directions reminds me of you (the therapist) talking to me during the rehabilitation sessions.”	1
“I would use the solution to prevent falls.”	1
“The solution helps me walk.”	1
“The solution helps me improve my motor perception.”	1
“I believe that the vest alone can play an important role in postural perception.”	1
“I think that using the solution after some rehabilitation sessions is better because right after the stroke, I could not minimally perceive or correct my posture.”	1

Postsession Interviews With Therapists

Responses to the adapted QUEST (version 2.0) questionnaire evaluating the solution as an assistive technology (Multimedia Appendix 1: App E) are summarized in Table 5. In total, 2 therapists provided a neutral rating for "Support to Posture" and "Audio guidance accuracy." They explained that patients with spatial orientation difficulties still required assistance from therapists despite using the solution. In total, 5 therapists provided neutral responses regarding "Solution trustworthiness." In total, 2 therapists recommended that the app recognize other body parts and suggested improvements in the instructions, noting that the app reinforced the user's reference sides.

We summarize the responses to evaluating satisfaction with Postural SmartVest on a 1-10 scale (Multimedia Appendix 1: App E) in Table 6. The responses indicated a highly positive impact on patients' posture control, with 95% rating it as "A lot." Additionally, 90% of the therapists believed that the app significantly contributed to achieving therapy goals. Moreover, 60% reported conducting fewer patient posture-related interventions after using the app. In terms of ease of use, 70% of the therapists found it "Very easy" for patients to follow the app's guidance.

Table 5. Therapists' responses to the adapted QUEST (version 2.0) questionnaire (1-5 scale).

Response	Rating 4 or higher, %	Indication
Support to Posture	90	Very satisfied
Audio guidance accuracy	90	Very satisfied
Device comfort	95	Very comfortable
Solution trustworthiness	83	Very reliable
Safety during use	100	Very safe
Likelihood to recommend	100	Very likely

Table 6. Therapists' satisfaction with SmartVest (1-10 scale).

Question	Percentage: answer	Indicating
Did you notice a positive impact on patients' posture control?	95%: 8 or higher	A lot
Do you think the app contributed to the therapy goals?	90%: 8 or higher	A lot
Did you notice if you conducted more or less posture-related interventions for patients?	60%: 3 or less	Fewer
How difficult was it for the patients to follow the app guidance?	70%: 3 or less	Very easy

Discussion

Principal Results

We designed Postural SmartVest, a solution consisting of a chest garment holding a smartphone running an Android application. When the user wears the Postural SmartVest in a rehabilitation session, the therapist first calibrates the app to the best posture the patient can achieve at the time. The app uses the smartphone accelerometer to identify variations in the user's body movement in the sagittal and frontal planes relative to the calibrated position. Based on these variations, the app provides multisensorial feedback that guides the patient to perform the movements required to return to the calibrated position.

The iterative development of Postural SmartVest, informed by therapist interviews and feasibility study feedback, tailored the final product to user needs. The app reliably identifies posture changes and provides corresponding multisensorial feedback, as substantiated by kinematic assessment.

Postural SmartVest significantly improved patients' ability to maintain their best-at-the-time postures, with patients showing a higher capacity for correct positions when using feedback. Although the analysis found no significant difference in the number of movements between stages, the increased movement during the feedback stage suggests an active engagement with the system for postural adjustments. This engagement aligns with rehabilitation goals, emphasizing motor skill enhancement and proprioception. These findings highlight Postural SmartVest's potential as an assistive technology for poststroke patients, emphasizing the importance of feedback in rehabilitation tools.

Postural SmartVest's flexibility meets each patient's unique needs and progress, with a highly customizable app enabling therapists to personalize feedback and adjust thresholds. This multisensory approach enhances engagement and may result in more effective posture correction. The app offers a comprehensive feedback system, including visual cues, tactile vibrations, and audio instructions.

The technology received positive feedback regarding its design and usability, with patients and therapists giving favorable ratings for various aspects of Postural SmartVest, including weight, comfort, dimensions, and effectiveness. Patients believed in its utility for walking assistance and motor perception improvement, and their suggestions aligned with their approval. Many patients were willing to recommend Postural SmartVest to other patients with poststroke hemiparesis, highlighting its perceived value. Healthy users also expressed satisfaction with Postural SmartVest's posture support.

Limitations

Our study used a specific sample of poststroke patients, which may not fully represent the diverse stroke survivor population. This highlights the need for including a broader and more diverse sample in future research. Although the findings indicate high satisfaction among both patients and therapists, individual preferences and responses varied. Patient feedback identified several limitations that suggest potential improvements to the app's personalization features, such as the ability to adjust the audio volume while using the vest and the inclusion of customizable vibration patterns and prompt frequencies. Additionally, enabling therapists to record guidance prompts in their own voices could enhance the patient experience, as one patient noted: “Listening to the app's directions reminds me of you (the therapist) talking to me during the rehabilitation sessions.”

The study’s duration might have limited the assessment of long-term effects, as improvements in posture maintenance could potentially change over time. A longer follow-up period could provide insights into whether the benefits observed are sustained in the long term. Additionally, the self-controlled approach used in the study—where participants served as their own controls by using the app with feedback turned off—may introduce bias related to user expectations and behavior. Future research should consider alternative control group designs to minimize potential biases and enhance the validity of the results. Another limitation of this study is the relatively unstructured approach to coding and scoring responses from interviews and feedback sessions. The multidimensional nature of the questions, ranging from levels of agreement to broader attitudes and preferences, presented challenges in achieving uniform analysis. To address this, we plan to use more structured, software-assisted procedures in future research to standardize data collection and analysis [68,69], thereby improving the consistency and depth of understanding gained from participant feedback.

Future research should also explore categorizing participants based on injury time, dominance, or body laterality to better understand the varying impacts of the Postural SmartVest. Including studies that involve patients using the device at home could provide insights into its real-world effectiveness and long-term impact in poststroke rehabilitation outside of clinical settings. Understanding how patients integrate the Postural SmartVest into their daily routines and the effects of extended, unsupervised use could reveal valuable information about its benefits in home-based rehabilitation. Furthermore, while Postural SmartVest records a range of activities, including posture changes and feedback delivery, it currently lacks features for therapists to access and use this data effectively. Future research should focus on developing these functionalities to enhance patient monitoring and rehabilitation planning. Additionally, addressing the requirements identified during initial therapist interviews, such as including a photo and video gallery and a dashboard for progress monitoring, could improve Postural SmartVest’s functionality and user satisfaction.

Comparison With Prior Work

Postural SmartVest is a modified athletic compression tank top with a transparent pocket for a smartphone running a customizable Android app. This app offers tactile vibrations, dynamic visual feedback, and clear audio instructions for posture monitoring and guidance. It is designed to be minimally intrusive, replicable, and useful for both therapists and poststroke patients, using readily available Android smartphones and avoiding the need for expensive specialized equipment.

The development of Postural SmartVest reflects the evolution of cognitive rehabilitation from classical methods to personalized systems with kinematic analysis and user-centered design [70]. It incorporates feedback from patients with stroke and therapists, aligning with recommendations for wearable technology design [71]. Unlike wearable rehabilitation systems that prioritize sensor accuracy over comfort [24], Postural SmartVest is distinguished by its comfort and effective smartphone placement, addressing both functional and user experience aspects.

Research on user perspectives for wearable systems in upper extremity stroke rehabilitation highlights the importance of monitoring both upper extremity and trunk movements and evaluating their quality and quantity [39]. In our experimental sessions, we included activities such as position maintenance, lateral trunk movements, trunk rotation, forward-backward trunk motions, and object retrieval, aligning with tasks assessed by various trunk ability evaluation tools [72]. While some studies have investigated smartphone-based training to improve balance and trunk performance among seated patients with stroke—using modified balance boards with visual and audio feedback in an external monitor [48,49] or smartphones attached to harnesses for screen feedback [25]—Postural SmartVest supports dynamic ambulatory movements and provides visual feedback directly on the smartphone screen, using a single color (red or green) to indicate posture status. This approach is particularly effective in therapy rooms with mirror walls and accommodates individuals with visual deficiencies, which are common after a stroke [73].

Postural SmartVest uses the smartphone’s accelerometer on the patient’s trunk to assist with trunk posture, while many studies use sensors on different body parts for various purposes [74-77]. While postural SmartVest uses smartphone-generated sensor data to identify trunk postures and facilitate posture correction, existing literature often combines data from multiple sensors placed on the user’s body for posture detection [78].

A wealth of research envisions using their solutions to foster collaboration among health professionals [79] or in the patient’s home environment, including studies that use smartphones as a communication component in a remote rehabilitation platform [18,25,33,35,70,76,80,81]. Although we designed Postural SmartVest primarily to assist patients during rehabilitation sessions, we are actively extending our research to the home environment by integrating Postural SmartVest with our experience sampling and programmed intervention platform [68].

Conclusions

Our goal was to create an affordable wearable, Postural SmartVest, aiding poststroke patients in posture maintenance during rehabilitation. Its simplicity and cost-effectiveness, using widely available devices with efficient sensors, enable multisensory feedback, enhancing accessibility. Patients and therapists expressed utility and satisfaction, emphasizing its clinical potential.

A comparison of patient session data using Postural SmartVest, both with and without feedback, informed essential insights. The significant difference in maintaining correct positions underscored the value of feedback. Although there was no disparity in the number of movements, the increased adjustments during sessions with feedback suggested active patient engagement. These findings emphasize the potential of Postural SmartVest as a valuable assistive technology for poststroke patients and highlight the importance of integrating feedback into rehabilitation tools.

Our study indicates several future research directions, including studying diverse stroke survivor populations, assessing long-term effects, exploring user engagement factors, and evaluating therapist training impact. Additionally, we should prioritize functional outcomes, technology adoption, cost-effectiveness, and addressing unmet needs like enhancing posture visualization and aiding long-term posture monitoring.

Abstract

Background: The atherosclerotic cardiovascular disease (ASCVD) is associated with dementia. However, the risk factors of dementia in patients with ASCVD remain unclear, necessitating the development of accurate prediction models.

Objective: The aim of the study is to develop a machine learning model for use in patients with ASCVD to predict dementia risk using available clinical and sociodemographic data.

Methods: This prognostic study included patients with ASCVD between 2006 and 2010, with registration of follow-up data ending on April 2023 based on the UK Biobank. We implemented a data-driven strategy, identifying predictors from 316 variables and developing a machine learning model to predict the risk of incident dementia, Alzheimer disease, and vascular dementia within 5, 10, and longer-term follow-up in patients with ASCVD.

Results: A total of 29,561 patients with ASCVD were included, and 1334 (4.51%) developed dementia during a median follow-up time of 10.3 (IQR 7.6-12.4) years. The best prediction model (UK Biobank ASCVD risk prediction model) was light gradient boosting machine, comprising 10 predictors including age, time to complete pairs matching tasks, mean time to correctly identify matches, mean sphered cell volume, glucose levels, forced expiratory volume in 1 second *z* score, C-reactive protein, forced vital capacity, time engaging in activities, and age first had sexual intercourse. This model achieved the following performance metrics for all incident dementia: area under the receiver operating characteristic curve: mean 0.866 (SD 0.027), accuracy: mean 0.883 (SD 0.010), sensitivity: mean 0.637 (SD 0.084), specificity: mean 0.914 (SD 0.012), precision: mean 0.479 (SD 0.031), and F_1-score: mean 0.546 (SD 0.043). Meanwhile, this model was well-calibrated (Kolmogorov-Smirnov test showed goodness-of-fit *P* value>.99) and maintained robust performance across different temporal cohorts. Besides, the model had a beneficial potential in clinical practice with a decision curve analysis.

Conclusions: The findings of this study suggest that predictive modeling could inform patients and clinicians about ASCVD at risk for dementia.

KEYWORDS

atherosclerotic cardiovascular disease; dementia; Alzheimer disease; vascular dementia; machine learning; UK Biobank

Introduction

Cardiovascular disease (CVD) is the leading cause of noncommunicable disease and mortality worldwide [1]. Meanwhile, the epidemiology of the atherosclerotic cardiovascular disease (ASCVD), which encompasses coronary heart disease and cerebrovascular disease (CeVD), has experienced substantial and rapid growth [2]. It is reported that in 2016, ASCVD was responsible for approximately 2.4 million deaths, representing 25% of all deaths and 61% of CVD-related deaths in China [3].

Dementia is another devastating disease affecting more than 50 million individuals worldwide [4]. Given the high costs and heavy burdens it imposes on families and society, scientists and scholars around the world are dedicated to identifying preventable interventions and reducing the incidence of dementia. Recently, a growing body of evidence indicates that lifestyle interventions early in life with a focus on reducing cardiovascular risk factors are a promising strategy for preventing dementia [5-9]. In particular, shared risk factors between dementia and ASCVD have been identified [10]. According to the Lancet Commission, it is estimated that approximately 40% of dementia cases can be prevented by targeting modifiable, primarily cardiovascular risk factors [4]. However, these studies were restricted by their use of classical statistical analyses (such as Cox or logistic regressions) and by considering only widely studied prespecified CVD risks. Therefore, the results were not sufficient in accuracy.

Machine learning (ML) is an emerging technical foundation of artificial intelligence, which enables the leverage of information from large and complex datasets [11]. Several studies have applied ML-based models to dementia diagnosis and risk prediction [12-15]. Nevertheless, the long-term risk of dementia progression (5 or 10 years) in patients with ASCVD remains uncertain.

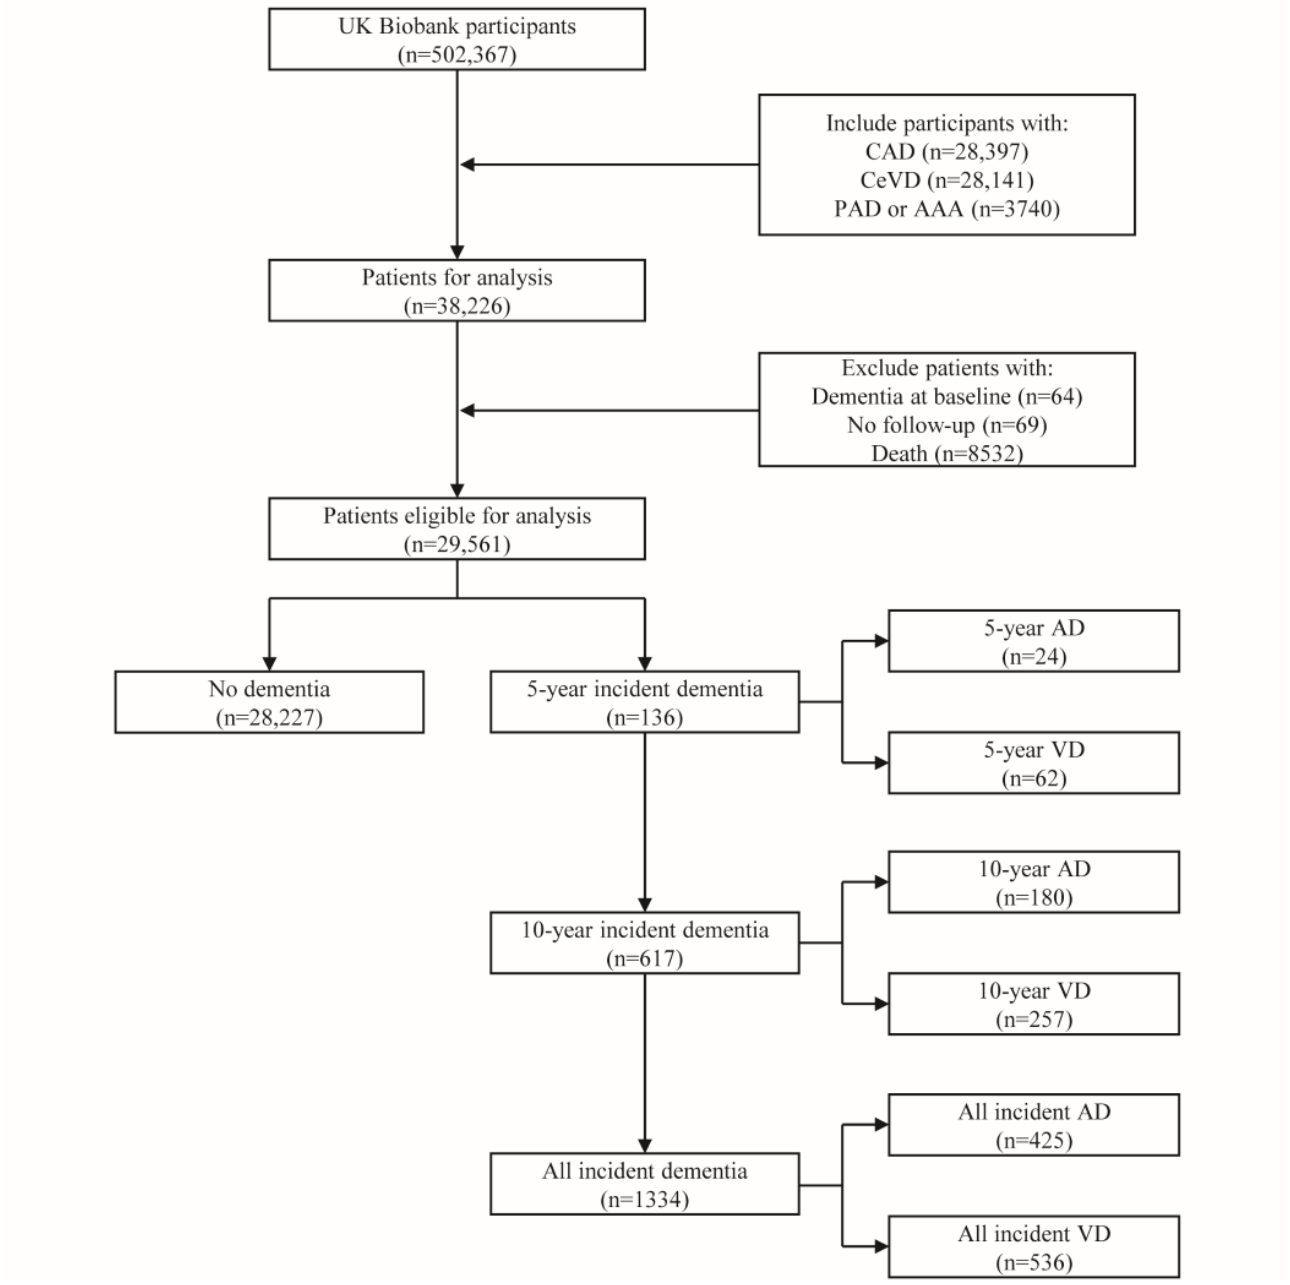
In this study, we used comprehensive phenotypic and follow-up data from a cohort of over 500,000 UK Biobank participants to develop an ML-based model capable of predicting the 5- or 10-year risk of incident dementia in specific patients with ASCVD. We anticipate that this ML-derived early warning system will enhance clinician-patient counseling, enable targeted follow-up, and facilitate the development of personalized prevention strategies. This, ultimately, can optimize the health and care of individuals with ASCVD.

Methods

Data Source and Study Population

We analyzed data from the UK Biobank, a longitudinal prospective study that recruited over 500,000 participants between 2006 and 2010 [16]. The participants were enrolled from 22 recruitment centers across the United Kingdom and were aged between 40 and 69 years at the baseline assessment. Multiple data were collected from the participants, including questionnaires, physical measurements, biological sample assays, genotyping, imaging data, and ongoing hospital records. Figure 1 illustrated the enrollment process, where we included individuals with a prior history of any established ASCVD, such as coronary artery disease (n=28,397), CeVD (n=28,141), peripheral artery disease, or abdominal aortic aneurysm (n=3740) [17]. Participants were excluded at the baseline assessment if they met the following criteria: (1) had dementia at baseline (n=64), (2) had no follow-up records (n=69), and (3) death (n=8532). Ultimately, we included 29,561 participants with ASCVD who had at least 10 years of follow-up until April 2023.

Figure 1. Participant selection flowchart. UK Biobank participants were excluded if baseline dementia was self-reported or follow-up data were absent. The remaining participants were categorized according to their first reported years of dementia, AD, or VD after the baseline. AAA: abdominal aortic aneurysm; AD: Alzheimer disease; CAD: coronary artery disease; CeVD: cerebrovascular disease; PAD: peripheral artery disease; VD: vascular dementia.



Ethical Considerations

Ethical approval was obtained from the North West Multi-Centre Research Ethics Committee (11/NW/0382, 16/NW/0274, and 21/NW/0157). Written informed consent was provided by all participants during the collection of primary data. The UK Biobank data used were deidentified, and all personally identifiable information of participants has been removed to ensure privacy and confidentiality. Besides, the UK Biobank offered nonfinancial compensation in the form of travel reimbursements for attending the assessment centers and other incidental expenses related to participation. Additionally, participants were given feedback on their individual health data upon request, which provided valuable insights into their health status. This study adhered to the reporting guidelines of Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis [18].

Outcome

The primary end point of this study was the occurrence of all incident dementia, including Alzheimer disease (AD), vascular dementia (VD), frontotemporal dementia, and dementia associated with other neurodegenerative or specified diseases. Due to the high rate of incidence worldwide, AD and VD were examined as the secondary outcomes. To conduct a comprehensive survey on the incidence time, we categorized the patients into 5-year, 10-year, and all incident dementia, AD, and VD. The outcomes were ascertained and categorized based on the International Classification of Diseases and Read codes (Table S1 in Multimedia Appendix 1), which were obtained

from the "first occurrence" category in the UK Biobank including the primary care data, the hospital inpatient data, the death register records, and subsequent UK Biobank assessment center visits. Follow-up visits continued until the earliest of the following events: a dementia diagnosis, death, or the most recent available data from either the hospital or the general practitioner, whichever occurred first. What is noteworthy was that the imaging data and lumbar puncture results were not available to doctors to achieve the detailed diagnostic data.

Data Preparation

In this study, we included all clinically correlated variables during the participants' baseline visits. The assessment procedure involved a manual examination of each variable to determine its relevance to comprehensively understanding a participant's overall status. Variables not pertinent to these key domains or lacking in additional insights were excluded. Data screening was processed to exclude noninformative variables with missing values exceeding 40% among all participants. To prevent potential overfitting from oversampling, we applied random undersampling to the majority class, balancing the dataset more effectively. We also adjusted the class weights in our ML algorithms to give more importance to the minority class during model training. Overall, a total of 316 features were adopted, including the participants' demographic characteristics (n=2), touchscreen-recorded questionnaires (n=151), physical measures (n=66), cognitive function tests (n=22), and biological sample assays (n=59). Furthermore, to improve the informative value of the dataset, we used the available data to generate several variables (n=16) that were not directly extracted from the UK Biobank (Table S2 in Multimedia Appendix 1). Considering the significant impact of ASCVD on mortality, we identified and coded deaths as competing events to ensure accurate modeling of the primary outcome.

In this study, we used different missing data handling strategies tailored to each ML algorithm to ensure the accuracy and robustness of the models. Specifically, for the logistic regression model, we used mean imputation to handle missing values. For each variable with missing data, we calculated its mean in the training dataset and replaced the missing data points with this mean. This method is simple and efficient, making it suitable for models like logistic regression that require complete datasets. For other ML methods, including light gradient boosting machine (LightGBM), extreme gradient boosting machine, random forest, k-nearest neighbor, and artificial neural network, we adopted automatic imputation techniques. These automatic imputation methods leverage the inherent mechanisms of the algorithms or advanced imputation strategies within the preprocessing pipeline to dynamically estimate and replace missing values. To evaluate the robustness of our results, we conducted a sensitivity analysis using multiple imputation by chained equations (Table S4 in Multimedia Appendix 1). This approach generates several imputed datasets by modeling each missing value conditionally based on other variables, thereby accounting for the uncertainty associated with the imputations. By comparing the outcomes across different imputation methods, we assessed the stability and reliability of our predictive models.

To evaluate the model's stability and generalization across different time periods, this study used a time validation approach to partition dementia data from the UK Biobank database. First, the recruitment date was selected as the primary temporal variable, and all samples were sorted in ascending order based on this date to ensure chronological arrangement and prevent future data from leaking into the training process. Considering previous research and data volume, the dataset was divided into 2 periods: the training and validation sets comprised samples recruited from 2006 to 2009, while the test set included samples diagnosed in 2010. This division ensures that only past data were used for model training, and the model's predictive performance on future data was assessed during the validation and testing phases. To further guarantee temporal independence, feature selection and standardization were performed exclusively on the training set, with identical transformations applied to the validation and test sets, thereby avoiding the use of information from these sets during training. Given the typically low number of dementia cases, healthy samples with more than 5% missing variables were excluded from the training set to balance the class distribution and enhance model learning. Additionally, multiple imputation methods were used to handle missing data, ensuring data integrity. Through these steps, a time validation framework was established, maintaining the temporal independence and appropriate distribution of the training, validation, and test sets, thereby improving the model's predictive performance across different time periods and the credibility of the study's findings.

Predictor Selection

The predictors for model development were identified through a 2-step process: variable importance ranking and sequential forward selection (SFS) [19,20]. First of all, the importance of each variable was determined using a preliminary trained LightGBM classifier. Gradient boosting machine is a type of boosting that builds these simple models step-by-step, improving the model at each step to better fit the data. LightGBM, developed by Microsoft, is a faster and more efficient version of gradient boosting machine designed to handle large-scale data effectively. The "light" in LightGBM refers to its lightweight nature, meaning it uses less memory and runs faster. The top 50 variables were selected by LightGBM. Next, they were inputted into a hierarchical clustering algorithm, which used Spearman rank-order correlations to further identify and eliminate redundant variables with multicollinearity. We established a correlation threshold of 0.75, considering variables with pairwise correlations above this value as highly redundant. Within each cluster of such variables, we retained only the most predictive variable for the model, effectively reducing multicollinearity while preserving essential information. To avoid overfitting and enhance the robustness of feature selection, a nested cross-validation approach was used. Specifically, in the outer loop, we divided the dataset into multiple folds, selecting 1 fold as the test set and using the remaining folds for feature selection and model training. Within the inner loop, the training set was further split into inner training and validation sets, where features were selected based on performance in the inner validation sets. Finally, model performance was evaluated on the outer test set to ensure fair feature selection and robust

predictive capability. Then, an SFS approach was used, wherein the features within the preselected subset underwent reranking according to a newly developed classifier. Afterward, preselected variables were reranked, and multiple ML classifiers were used to sequentially add predictors one at each time. Finally, the classifier was selected based on achieving the best performance of area under the receiver operating characteristic curve (AUC), and we selected the top 10 variables according to the importance of each variable calculated by the LightGBM model. After selecting these 10 variables, adding any other variables did not significantly improve the model. The top 25 predictors are shown in Table 1. More details of predictor selection could be obtained in the part of the Methods section in Multimedia Appendix 1.

Table 1. Top 25 predictors for all incident dementia with light gradient boosting machine.

Number	Variables	Importance rating	Ranking
1	Forced vital capacity	0.133	1
2	Summed MET[a] minutes per week for all activity	0.12	2
3	Age	0.09	3
4	Pairs matching time	0.05	4
5	Mean sphered cell volume	0.038	5
6	Glucose	0.037	6
7	Mean time to correctly identify matches	0.037	7
8	FEV1[b] *z* score	0.035	8
9	Age first had sexual intercourse	0.033	9
10	C-reactive protein	0.031	10
11	Average weekly red wine intake	0.029	11
12	Calcium	0.029	12
13	Vitamin D	0.028	13
14	Pulse rate automated reading	0.026	14

24	Average weekly beer plus cider intake	0.017	24
25	Result ranking	0.016	25

[a]MET: metabolic equivalent.

[b]FEV1: forced expiratory volume in 1 second.

[c]FVC: forced vital capacity.

Model Development

We implemented a range of ML techniques, including LightGBM, extreme gradient boosting machine, random forest, logistic regression, k-nearest neighbor, support vector machine, and artificial neural network to classify participants into 2 classes: 0 (predicted to remain no dementia) or class 1 (to develop all incident dementia, AD, or VD). The proposed model was developed using patients with ASCVD without dementia (n=28,227) and with all incident dementia (n=1334) from the UK Biobank dataset. In total, 10 identified predictors were incorporated into the model. We expanded our performance evaluation metrics to include receiver operating characteristic-AUC, precision, recall, and F_1-score, ensuring a comprehensive assessment of the models' performance on imbalanced data. Subsequently, LightGBM, the best-performing method, was used to develop a dementia risk prediction model of ASCVD, named the UK Biobank ASCVD risk prediction model. The hyperparameter tuning was performed through exhaustive selection from 10,000 sets of candidate parameters,
