Journal Impact Factor (JIF) (2023): 5.0
Volume 9 (2026) ISSN 2561-7605 Editor in Chief: Yun Jiang, PhD, MS, RN, FAMIA; Jinjiao Wang, PhD, RN, MPhil

Contents

Original Papers

A Novel Multisegmental Individual-Based Exercise Approach for Postural Dysfunction and Balance Impairment in Older Adults: Randomized Controlled Trial (e78426)
Filza Shoukat, Syed Ur Rehman. . . . 15

Effects of a Combined Zumba and Video Game–Based Cognitive Intervention on Cognitive Function Among Older Adults in Klang Valley, Malaysia: Semirandomized Trial (e88479)
Yook Chia, Sharifah Syed Annuar, Jactty Chew, Yunli Lee, Wei-Gene Lim, Wei Yip, Kristin-Ann Zhe Mun, Michael Jenkins. . . . 29

Motivations, Barriers, and the Potential of AI in Physical Activity Apps for US Older Adults: Interview Study (e96114)
Abhinav Choudhry, Jonathan Mshvelidze, Sean Mullen, Devorah Kletenik, Rachel Adler. . . . 46

Association Between a Hybrid Video-Guided Multicomponent Exercise Program With Staff Assistance and Free-Living Gait in Older Adults With Knee and Low Back Pain: Secondary Analysis of a Randomized Controlled Trial (e97414)
Shuichi Obuchi, Tomoyuki Arai, Hideaki Ishibashi, Takashi Amari, Hisashi Kawai. . . . 63

Community Exergaming and Maintenance-Related Outcomes in Older Adults: Multi-Wave Observational Evaluation (e100007)
Yuezhong Liu, Bing Chia, Herng Koh, Quoc Nguyen, Jiahui Jin, Kimberly Tan, Samuel Long, Yin-Leng Theng. . . . 77

Domain-Specific Associations of Physical Activity With Phase Angle and Extracellular Water–to–Total Body Water Ratio in Middle-Aged or Older Adults: Cross-Sectional Study (e90158)
Seong-Uk Baek, Jin-Ha Yoon. . . . 89

Tailored Online Physical Activity Coaching for Middle-Aged and Older Adults With Cognitive and Mental Health Concerns: Single-Arm Pre-Post Intervention Study (e80040)
Kathryn Ellis, Rhoda Lai, Eleanor Curran, Jennifer Southam, Rebecca Moorhead, Kay Cox, Serafino Mancuso, Alissa Westphal, Terence Chong, Thomas Rego, Victoria Palmer, Kaarin Anstey, Nicola Lautenschlager. . . . 100

Dose-Related Effects of Different Tai Chi Styles Versus Traditional Community-Based Exercises on Cardiometabolic Health and Physical Function in Middle-Aged and Older Adults: Randomized Controlled Trial (e80125)
Jiadong Qiu, Jian Wang, Xiongying Song, Wanyu Shu, Sung Kim. . . . 121

Interactive Vision–Based 3D Augmented Reality System for In-Home Rehabilitation in Older Adults Following Total Joint Replacement: Cross-Sectional Survey of Patients and Service Providers (e87572)
Adriana Salvia, Siona Phadke, Manuela Kunz, Afolasade Fakolade. . . . 140

The 4 Ss Framework for Designing Age-Friendly Communities of the Future: Focus Group Study (e90923)
Inga Hunter, Caroline Lockhart. . . . 156

Smart Speaker–Based Applications to Support Social Connectedness in Older Adult Residents in Affordable Housing: User-Centered Design Study (e90053)
Jane Chung, Natalie Mansion, Tracey Gendron, Rachel Wood, George Demiris. . . . 170

Evaluation of a Gamification-Based Intervention to Enhance Intergenerational Communication: Pre-Post Mixed Methods Evaluation (e77190)
Eliza Wong, Clement Ng, Dorothy Wang, Carol Wong, Shirley Lui, Annie Cheung, Eng-kiong Yeoh. . . . 189

The Influence of Robot Facial Expression and Inclusion Behavior on Rapport and Trust in Older Adults: Mixed-Factorial Experimental Study (e91235)
Hsiu-Ping Yueh, Kuang-Chi Lin, Weijane Lin. . . . 206

Perceived Use of Web-Based Videoconferencing for Social Connectedness Among Older Adults Living in Long-Term Care: Qualitative Study (e73213)
Anna Garnett, Halyna Yurkiv, Denise Connelly, Richard Booth, Lorie Donelle. . . . 220

Association Between Loneliness, eHealth Literacy, and Quality of Life Among Chinese Older Adults: Cross-Sectional Study (e88600)
Shouchuang Zhang, Jiayi Li, Jia Tang, Weiyan Jian, Qing Liu, Jing Guo. . . . 235

Daily Monitoring of Behavioral and Psychological Symptoms of Dementia in Residential Care: Mixed Methods Pilot Study (e98024)
Johannes Malm, Therése Bielsten, Charlotta Nilsen, Elzana Odzakovic, Ingemar Kåreholt. . . . 247

Effect of an Intersectoral Telemedicine Intervention on Hospitalization in Nursing Home Patients: Specification Curve Analysis of a Stepped Wedge Cluster Randomized Trial (e75721)
John Grosser, Sophie Pauge, Birthe Aufenberg, Wolfgang Greiner, Miriam Hertwig, Jenny Unterkofler, David Brücken, Christian Hübel, Optimal@NRW Research Group, Jörg Brokmann. . . . 266

Predicting Care Needs in Community-Dwelling Older Adults Using Explainable Machine Learning and a Multidimensional Approach Integrating Health, Social, and Environmental Factors: Cross-Sectional Study (e93371)
Hyeri Shin. . . . 292

Providing Tech Support as Care Work Among Care Workers in Assisted Living Facilities: Qualitative Interview Study (e80272)
Yiyi Wu, Nicole Ross, Sunyoung Kim. . . . 312

Large Language Model–Based Identification of Subjective Cognitive Decline in Electronic Health Records Among Older Adults With Normal Cognitive Testing: Retrospective Cohort Study (e93011)
Liqin Wang, Rebecca Amariglio, Sheril Varghese, Jiazi Tian, Diane Seger, Li Zhou, Gad Marshall. . . . 326

Development and Temporal External Validation of a Parsimonious, Interpretable Machine Learning Model for Predicting 6-Month Mortality in Long-Term Care Facilities: A Retrospective Cohort Study (e94567)
Yun-Cheng Tsai, Yi-Lin Wu, Yung-Chen Yu, Yi-Wen Chen, Yi-Wen Chen, Yi-Ching Yang, Yu-Tai Lo. . . . 342

A Smart Wheeled Walker With Integrated Physiological Monitoring to Improve Mobility in Older Adults: Randomized Crossover Trial (e99522)
Phurichaya Werasirirat, Pornpimol Muanjai, Oranat Sukkho, Nongnuch Luangpon, Audrius Snieckus, Juntip Namsawang. 367

Leveraging Digital Health Technologies to Assess Older Adults' Frailty and Nutritional Status: Two Cross-Sectional Studies (e77816)
Nunzio Camerlingo, Madisen Wicker, Dimitrios Psaltos, Nina Shaafi-Kabiri, Hao Zhang, Andrew Messere, Isabelle Messina, Zachary Hayden, Meredith Kelly, Gauri Kamat, Fikret Karahano lu, Charmaine Demanuele, Mar Santamaria, David Caouette, Kevin Thomas. 379

Knowledge Performance, User Experience, and Cybersickness With Immersive Virtual Reality for Tai Chi Movement-Encoding in Older Adults: Randomized Comparison Study (e96867)
XiaCheng Song, Lu Sun, Yaqing Song, Huafeng Qu, Jing Jin, Junfeng Zhu, Wenwen Song, Huirong Huang. 398

Assessing a Digital Platform (KOKU-Nut) to Improve Nutrition in Older Adults: Mixed Methods Feasibility Randomized Controlled Trial (e87351)
Chloe French, Sorrel Burden, Jaheeda Gangannagaripalli, Emma Stanmore. 413

Developing Digital Platforms to Help Older Adults Stay Physically and Socially Active: Co-Design Study to Develop a Toolkit and Evaluate Its Impact (e89785)
Leonie Cooper, Hannah Bradwell, Colin Shore, Simone Tomaz, Rory Baxter, Gemma Ryde, Swen Gaudl, Richard Haynes, Catherine Hennessy, Ray Jones, Anna Whittaker, The GOALD Project. 427

Measuring Implicit Attitudes Toward Digital Health Technologies in Older Adults Using an Influence-Aware Affect Misattribution Procedure: Development and Feasibility Study (e87989)
Anna Vinnikova, Jinyue Zhan, Kailing Jin, Xianfeng Ding, Wei Sang, Weina Xu, Qian Yang. 446

Development and Evaluation of a Transportation Planning e-Tool for Older Adults: Co-Design Study (e88297)
Sara Bahrampoor Givi, Dany Baillargeon, Sahar Tahir, Bessam Abdulrazak, Mireille Gagnon-Roy, Mélanie Levasseur, Nathalie Delli-Colli, Patrick Boissy, Mélisa Audet, Véronique Provencher. 461

Telemonitoring Adoption Among Older Adults: Sequential Mixed Methods Study of Message Framing and Structural Influence (e89817)
Dandan Wang, Huanyu Bao, Amber Qua, Gaelmaine Hoong, Pei He, Ern Ong, Edmund Lee. 483

Usability of the Coach-Supported Dementia Prevention App ENHANCE (Tailored Intervention for Brain Health and Cognitive Enrichment) in Older Adults: 1-Week Mixed Methods Study (e92800)
Tsz Yu, Gill Livingston, Richard Boczko, Kealan Forristal, James Jamison, Carl Leckstein, Vrushti Mehta, Hee Park, Aneesha Singh, Andrew Sommerlad, Sergi Costafreda. 502

Personalized Predictive Model to Predict Subtask Success of Medication Adherence Technologies for Older Adults With Diverse Capabilities: Development and Internal Validation Study (e84616)
Bincy Baby, Ghada Elba, Minzee Kim, SooMin Park, Imra Hudani, Rishabh Sharma, Halak Patel, Sidharth Bajaj, P Patterson, Annette McKinnon, Sara Guilcher, Feng Chang, Linda Lee, Catherine Burns, Ryan Griffin, Joslin Goh, Tejal Patel. 522

Exploring Information Access in Aging Populations and Those With Dementia and Mild Cognitive Impairment in the United Kingdom: Survey and Focus Group Study (e85626)
Claire Rogers, William McGeown, Yashar Moshfeghi. 540

Smartphone Use and Social Activities Among People With Mild to Moderate Dementia: Multi-Informant Cross-Sectional Study (e81927)
Shuji Tsuda, Satoko Hotta, Hiroshige Matsumoto, Kae Ito. 559

Smart Glasses for Older Adults With Cognitive Impairment: Explanatory Mixed Methods Study (e81840)
Brittany Burch, Nayeon Kim, Rachel McPherson, Debora Anokye, Alice Ryan, Odessa Addison, Nirmalya Roy, Chien-Ming Huang, Elizabeth Galik, Barbara Resnick. 573

Development of a Web-Based Resource to Support Driving Safety in Older Adults: Semistructured Interview and Focus Group Study (e79630)
Mollie Cahill, Ranmalee Eramudugolla, Marwin Tang, Diane Hosking, Stephen Cratchley, Michael Regan, Lesley Ross, Jasmine Price, Kaarin Anstey. . . . 589

Web-Based Gamified Auditory-Cognitive Dual-Task Training for Older Adults With Age-Related Hearing Loss: Pilot Randomized Controlled Trial (e84083)
Ivy Zhao, Angela Leung, Chen Li, Laurence Lloyd Parial, Hongming Ma, Jed Montayre, Justin Golub, Robert Sweetow, Janet Ng, Engle Chan.
6 0 0

Usability and Adoption of Smartwatches by Older Adults in Bangladesh: User Study (e76404)
Fariah Mahzabeen, Fazlea Rabby, Neazmul Mowla, Sadia Ibnat. . . . 619

A Tablet Computer–Based Food Record for the Self-Assessment of Nutritional Intake in Patients Undergoing Geriatric Rehabilitation: Prospective Pilot Feasibility Study (e84653)
Julia Berndt, Patrick Elfert, Marco Eichelberg, Juergen Bauer, Andreas Hein, Rebecca Diekmann. . . . 643

Performance-Based Usability of Medication Adherence Technologies Among Older Adults With Diverse Capabilities: Quantitative Study (e88398)
Bincy Baby, Ghada Elba, SooMin Park, Imra Hudani, Rishabh Sharma, Kirk Patterson, Annette McKinnon, Sara Guilcher, Feng Chang, Linda Lee, Catherine Burns, Dagmar Hajducek, Ryan Griffin, Tejal Patel. . . . 657

Predictive Model of Acupuncture Adherence in Alzheimer Disease: Secondary Analysis of Randomized Controlled Trials (e82787)
Ze-Hao Chen, Ran Li, Yu-Hang Jiang, Jia-Kai He, Shan-Shan Yan, Guan-Hua Zong, Zong-Xi Yi, Xin-Yu Ren, Bao-Hui Jia. . . . 678

The Virtual Kitchen Challenge—Version 2: Validation of a Digital Assessment of Everyday Function in Older Adults (e82092)
Marina Kaplan, Moira McKniff, Stephanie Simone, Molly Tassoni, Katherine Hackett, Sophia Holmqvist, Rachel Mis, Kimberly Halberstadter, Riya Chaturvedi, Melissa Rosahl, Giuliana Vallecorsa, Mijiail Serruya, Deborah Drabick, Takehiko Yamaguchi, Tania Giovannetti. . . . 693

Developing Consumer Consensus on Remote Assessment and Management of Physical Function in Older Adults (RAMP): International Modified Delphi Process (e75791)
Elsa Dent, Christopher Hurst, Jack Dalla Via, Jackson Fyfe, Paul Jansons, Eleanor Hayes, Gary Skinner, Marc Sim, Mylene Aubertin-Leheudre, Sabine Britting, Fanny Buckinx, Gavin Connolly, Ruth Dignam, Lora Giangregorio, Jennifer Jones, Pauline Kelly, Robert Kob, Suzanne Morin, Girish Nandakumar, Lucas Orssatto, Maria Pearson, Daniel Pinto, Esmee Reijnierse, Catherine Said, Mohamed Salem, Vina Tan, Rosanna Tran, Jesse Zanker, Robin Daly, David Scott. . . . 713

Effects of a Virtual Reality–Based Natural Environment Intervention on Attention and Mood in Community-Dwelling Older Adults: Randomized Controlled Trial (e87861)
Cheng-Chen Chou, Jong-Ni Lin, Chia-Pin Yu, Chi-Wen Chen, An-Yun Yeh, Yen-Kuang Lin. . . . 731

Evaluating the Use of Generative AI Videos for Health Self-Management of Older Adults: Mixed Methods Study (e88005)
Ting Liu, Patrick Pang, Yiming Luo, Dana McKay, George Buchanan, Shanton Chang. . . . 744

360°-Based Cognitive-Motor Training System for Older Adults With Cognitive Impairment: User-Centered Design and Evaluation Study (e68032)
Francesco Bigotto, Jonathan Panigada, Francesca Bruni, Valentina Mancuso, Silvia Cavedoni, Marco Stramba-Badiale, Karine Goulene, Elisa Pedroli, Silvia Serino. . . . 761

Adoption and Use of a Smart Home Connected Care System by Older Adults: Mixed Methods Study (e76012)
Laura Pemberton, Michelle Carter, Nikolay Mehandjiev. . . . 780

A Multidimensional Digital Health Platform to Support Intrinsic Capacity and Healthy Aging: Pilot Feasibility Study (e79862)
Marcin Kolakowski, Andrea Lupica, Seif Bader, Jaouhar Ayadi, Luca Gilardi, Angelo Consoli, Irina Mocanu, Oana Cramariuc, Lionello Ferrazzini, Eva Reithner, Magdalena Velciu, Barbara Borgogni, Sofia Rivaira, Luca Antognoli, Sara Leonzi, Elisa Felici, Margherita Rampioni, Giacomo Cucchieri, Vera Stara. . . . 795

A Community-in-the-Loop Approach to Smart Home Monitoring for Aging in Place: Mixed Methods Evaluation of a Co-Designed Prototype (e88290)
Roschelle Fritz, Connie Nguyen-Truong, Jennifer Phipps, Ellen Hinderlie, Yolanda Rodriguez, Thai Nguyen, Gabrielle Barling, Anna Mishuk, Heather Schoonover, Christi Zuber, Marilyn Rantz. . . . 819

Smart Home Technology Integration in Home Modification Programs Serving Older Adults: Focus Group Study With Program Grantees (e89729)
Haomin Hu, Moriah Clarke, Meredith Hughes, Palash Sharma, Jack Fried, Portia Singh, Pamela Toto. . . . 834

A Music Interaction System Based on the Emotional Recognition of Older Adults in Smart Homes: Cross-Sectional Experimental Study (e77218)
Chengmin Zhou, Yuxuan Luo, Wenjing Zhan, Ting Huang, Jake Kaner. . . . 845

Feasibility of a Co-Designed Personalized Cognitive Reablement Program Delivered via Digital Voice Assistants for Older Adults Living With Early-Stage Dementia or Mild Cognitive Impairment: Pilot Randomized Controlled Trial (e96922)
Tracy Yiannis, Helen Macpherson, David Scott, Michele Callisaya, Celeste Chapple, Costas Glavas, Caitlyn Gourlay, Ralph Maddison, Eugene Gvozdenko, Paul Jansons. . . . 873

Public-Facing Communication of Health and Social Services for Older Adults and Their Family or Friend Caregivers: Environmental Scan of 58 Integrated Care Teams' Websites in Ontario, Canada (e80595)
Hung Nguyen, Kyle Corbett, Deanna Vervaecke, Natalia Ivanovski, Soroush Shirazi, Sara Yadollahi, Hom Shrestha, Irene Slavescu, Behnoush Zarandi Baghini, Stella Medvedyuk, Matthias Hoben. . . . 890

A Telehealth-Adapted Dementia Caregiver Skills Training Intervention (TeleCARE): Single-Arm Pre-Post Intervention Study (e81256)
Maureen O'Connor, Steven Shirk, Jaye McLaren, Andrew Nguyen, Kendra Pugh, Madeline Sullivan, Emily Metcalf, Samantha Harrington, Lauren Moo. . . . 904

Integrating Perceived Psychosocial Outcomes Into the Assessment of Telecare Acceptability Among Slovenian Informal Caregivers of Older People: Cross-Sectional Survey Study (e85534)
Vesna Dolni ar, Nejc Berzelak, Sakari Taipale, Simona Hvali -Touzery. . . . 919

Characterizing Digital Mindfulness Intervention Utilization and Weekly Assessments in Caregivers of Persons Living With Dementia: Secondary Analysis of a Randomized Controlled Trial (e83618)
Michael Williams, Darby Simon, Morgan Seward, Raquel Tatar, Jennifer Huberty, Ana-Maria Vranceanu, Evan Plys. . . . 936

Developing and Testing a Brief Mindfulness Just-in-Time Adaptive Intervention to Reduce Stress Among Caregivers of People With Dementia: Quasi-Experimental Study (e87316)
Patrick Kor, Alex Tsang, Daphne Cheung, Steven Zarit, Haoran Xie, Min Qian, Kay Tan, Yuanqing Zheng, Amanda Chu, Kee Chou. . . . 949

Combining Subjective Perceptions and Objective Behavioral Metrics With the Elderly Digital Twin System: Quantitative Usability Study (e91873)
Ziaullah Momand, Pornchai Mongkolnam, Debajyoti Pal, Siam Yamsaengsung. . . . 965

Multidimensional Digital Literacy and Quality of Life Among Informal Care Dyads in Malaysia: Cross-Sectional Survey (e86561)
Fereshteh Mohammadzadeh Yazd, Hui Foong, Rahimah Ibrahim, Puvaneswaran Kunasekaran, Asmidawati Ashari. . . . 992

Rationale, Design, and Baseline Characteristics of the TARGET (Targeted Assessment and Recruitment of Geriatrics for Effective Fall Prevention Treatments) Cohort of Older Adults for Assessing Fall and Fracture Risk: Prospective Cohort Study (e89285)
Angelique Chan, Abhijit Visaria, Rahul Malhotra, Navrag Singh, Benedikt Helgason, Victor Schinazi, Kok Tan, David Matchar, Rita Sim, Vanessa Koh, Wei Lai, Lakkhina Troeung, Catherine Lim, Sai Pai, Kai Tan, Anitha Praveen, Dheeraj Jha, Stephen Ferguson, Giorgio Colombo, Karolina Minta, Ecosse Lamoureux, William Taylor. . . . 1039

Development and Validation of Machine Learning Models for Predicting Falls Among Hospitalized Older Adults: Retrospective Cross-Sectional Study (e80602)
Xiyao Yang, Juan Ren, Dan Su, Manzhen Bao, Miao Zhang, Xiaoming Chen, Yanhua Li, Zonggui Wang, Xiujing Dai, Zengzeng Wei, Shuiyu Zhang, Yuxin Zhang, Juan Li, Xiaolin Li, Junjin Xu, Nan Mo. . . . 1065

Global, Regional, and National Burden of Falls Among Older Adults Aged 65 Years and Above: Secondary Data Analysis of the Global Burden of Disease Study 2021 (e73802)
Ze Zhang, Yingying Diao, Mingwang Fu, Wantong Han, Haoran Zhou, Ru Fan, Biyun Xu, Bingwei Chen. . . . 1080

Supervised and Self-Directed Technology-Based Dual-Task Exercise Training Program for Older Adults With a History of Falls: Mixed Methods Feasibility Study (e87577)
Prerna Mathur, Afroditi Stathi, Victoria Goodyear, Taylor Krauss, Helen Thomas, Angela Cooper, Philip Kinghorn, Caroline Miller, Natalie Ives, Magdalena Chechlacz, Daisy Wilson, Laura Magill, Shin-Yi Chiou. . . . 1092

Impact of Sleep Quality on Gait Variability: Pilot Cohort Study (e81630)
Francesca Marino, Minzae Kim, Phillip Hwang, Yorghos Tripodis, Michael Alosco, Jesse Mez, Ann McKee, Rhoda Au, Robert Thomas, Ludy Shih. . . . 1107

Feasibility and Preliminary Effects of a Pressure Sensor–Based Exergame on Cognitive and Sensorimotor Frailty in Low-Income Older Adults Receiving Public Community Care Services: Pilot Randomized Controlled Trial (e93467)
Sunmi Song, Suk-Chan Hahm, Seyun Chang, Jinseung Lee, Heewon Kang, Sang Lee, Junesun Kim. . . . 1120

Associations of Midlife Gait Speed and Muscle Performance With Falls in Later Life: Secondary Analysis of the MIDUS Cohort (e103917)
Roee Hayek, Yaniv Nudelman, Dan Keren, Shmuel Springer. . . . 1140

An Ultra-Brief Informant Questionnaire for Case Finding of Cognitive Impairment Across Diverse Literacy: Diagnostic Accuracy Study (e72963)
Tau Liew, King Yip, Kaavya Narasimhalu, Simon Ting, Weishan Li, Sze Tay, Way Koay. . . . 1152

Data-Driven Phenotyping Reveals Nonuniform Association Between Age and Mortality After Aortic Surgery: Retrospective Cohort Study of UK Biobank Data (e75611)
Maria Leinweber, Fadi Taher, Miriam Kliewer, Afshin Assadian, Amun Hofmann. . . . 1172

Associations of Solid Fuel Use and Circadian Rhythm Syndrome With Physical Function and Muscle Strength in Middle-Aged and Older Adults: Nationwide Cohort Study in China (e78352)
Haochen Wang, Pengsen Mou, Donghao Liu, Ze Zhao, Wenzheng Chen, Yuxin Yao, Haoyan Shi, Jiaxin Guan, Jing Dong, Yingliang Wei. . . . 1 1 8 6

Fear-Specific Technophobia as a Mediator Between Daily Technical Support and Instrumental Versus Hedonic Technology Use in Later Life: Cross-Sectional Survey Study (e93063)
Yu Yang, Shuo Dai, Siyu Yin, Wanyu Xi, Qi Li. . . . 1202

Gaps Between Self-Reported and Documented Use of a Health Care Service Portal Among Older Adults: Cross-Sectional Survey and Retrospective Electronic Data Study (e93057)
Efrat Neter, Diane Levin-Zamir, Ester Eliyahu, Peter Chang, Tuyen Duong, Orna Baron-Epel. . . . 1225

Patient Satisfaction With Telehealth Visits in Rural Compared With Urban Communities: Single-Center Study (e85018)
Corrin Hepburn, Karolina Krawczyk, Cara Joyce, Jonah Rubin. . . . 1238

Digital Self-Efficacy, Satisfaction With the Daily Life Changes Stemming From Digital Transformation, and the Moderating Effect of Social Capital in Middle-Aged and Older Adults: Cross-Sectional Survey Study (e79845)
Jeongeun Choi, Hyeonmi Cho, Hyangkyu Lee. . . . 1247

Digital Inclusion Pathways for Older Chinese Adults in the Context of Active Aging: Secondary Analysis of 2023 China Longitudinal Aging Social Survey Data (e83078)
Bo Zhao, Xiaoyan Wang, Ren Chen, Eun Nam. . . . 1264

Broadband Access, Internet Use, and General Cognition in Middle-Aged and Older Adults: Longitudinal Study (e75947)
Fangfang Cheng, Li Cao. . . . 1279

Factors Associated With the Use of Digital Health and Well-Being Resources in Non–Memory-Led Dementias: Quantitative Survey Study (e85863)
Emilie Brotherhood, Céline El Baou, Caroline Fearn, Oliver Hayes, Nikki Zimmermann, Anastasia Tsipa, Sebastian Crutch, Joshua Stott. . .
1 2 9 5

Attitudes Toward Digital Meal Assistance Services Among Older Adults in China: Cross-Sectional Survey (e84956)
Zhe Chen, Tinghe Deng, Xiaoli Zhu. . . . 1310

Development of the Windmill Model for Mapping Older Adults' Intrinsic Capacity Using Digital Twin Technology: Descriptive Qualitative Study (e81075)
Yirou Niu, Zehui Xuan, Yanling Wang, Xiaoya Zhang, Yibo Guo, Xin Li, Shuai Jin, Jie Zhao, Qian Xiao, Hong Chang. . . . 1324

Segmentation of Older People's Needs and Readiness for Smart Homes by Residentially Based Lifestyles in Spain: Survey Study (e75110)
Jiyeon Yu, Angélica de Antonio, Elena Villalba-Mora. . . . 1340

Web-Based Application to Support Caregivers in the Use of Learning Optimization Methods: Participatory Action Research Study (e76543)
Chantal Viscogliosi, Hubert Ngankam, Romane Duquette-Laplante, Sarah Rahimaly, Hélène Pigot, Bernard Chassé, Sara Ait Bouziaren, Yves Couturier, Jessica Déry, Nicolas Biard, Jordan Duchesne, Dominique Giroux, Sabrina Jacob, Kim Routhier-Chevrier, Jordan Mino-Roy, Mélanie Caron, Véronique Provencher. . . . 1356

Level of eHealth Literacy and Its Associations With Health Behaviors and Outcomes in Chinese Older Adults: Cross-Sectional Analysis of Baseline Data From a Large-Scale Community Project (e74110)
Siu Chau, Wanjia He, Tzu Luk, Sophia Chan. . . . 1369

From Digital Anxiety to Empowerment in Older Adults: Cross-Sectional Survey Study on Psychosocial Drivers of Digital Literacy (e75245)
Han-Jen Niu, Ming-Hsuan Li, Feng-Yu Hsieh, Chun-Chieh Yu, Chun-Ting Lin. . . . 1386

Smartphone Addiction, Use Preferences, and Depression Among Older Adults in the Digital Context: Machine Learning Analysis of Survey Data (e84703)
Sheng Chen, Yue Song, Chien-chung Huang. . . . 1403

Self-Identified Age Cohorts and Personal Experience Sharing in Pseudonymous Online Spaces: Natural Language Processing Analysis of Reddit (e90103)

Abstract

Background: Age-related decline in mobility and balance substantially increases the risk of falls in older adults. Evidence-based exercise programs are recommended, but their effectiveness requires further evaluation.

Objective: The study aimed to find out the effectiveness of multisegmental individual-based exercise program (MIBEX) approach for postural dysfunction and balance impairment in older adults.

Methods: A 2-arm, single-blinded randomized controlled trial was conducted with 113 community-dwelling adults aged 65 years or older (exercise group, n=56; control group, n=57). Participants in the intervention arm received MIBEX, while the control group received postural education via video. Outcomes included the Timed Up and Go test, tragus-to-wall test, Mini-Balance Evaluation Systems Test, and postural sway, measured at baseline and 3 postintervention time points. Between-group comparisons were analyzed using the Mann-Whitney *U* test with effect sizes (*r*) and 95% CIs.

Results: Significant between-group differences were observed across all outcomes ($P<.01$). The exercise group showed improvements in the Timed Up and Go test (median reduction from 15, IQR 13 - 19 to 10, IQR 8 - 12 s) compared with controls (15, IQR 13-18 to 12, IQR 10-14 s), with a large effect size ($r=0.65$, 95% CI 0.45 - 0.80). Tragus-to-wall test performance improved markedly in the intervention group (median increase from 41, IQR 36-47 to 49, IQR 44-54 cm) versus controls (40, IQR 35-46 to 37, IQR 31-43 cm; $r=0.52$, 95% CI 0.30 - 0.70). Mini-Balance Evaluation Systems Test scores declined in controls but improved in the intervention group ($r=0.48$, 95% CI 0.25 - 0.66). Postural sway demonstrated moderate improvement ($r=0.40$, 95% CI 0.18 - 0.58).

Conclusions: These findings indicate that the MIBEX produced significantly greater improvements in mobility, balance, and postural stability compared with usual care, highlighting its potential as an effective intervention for older adults.

Trial Registration: Iranian Registry of Clinical Trials IRCT20221005056094N1; https://www.irct.ir/trial/66236

KEYWORDS

exercise; old age; posture; balance; physical function

Introduction

The 2019 United Nations World Population Prospects data show that approximately 8% of the global population is currently aged 65 years or older, and this figure is projected to reach almost 16% by 2050 [1]. The fastest-growing demographic population is the older adult population aged 80 years and above. Concerns are increasing regarding the increasing proportion of older individuals compared with the total population. It is estimated that by 2030, the percentage of older adults in the total population will increase by 9.3% [2]. According to the Global Burden of Disease Study, the percentage of years lived with disability has increased by 7.9% in men and by 6.5% in women from 1990 - 2017 [3]. Approximately two-thirds of the older adult population lives in low- to middle-income countries, and like many others, Pakistan also experiences a demographic shift. This shift has significant health, social welfare, and economic development implications [4].

Aging is an ongoing and irreversible process resulting in changes in body composition, which affect physical fitness. Physical fitness decreases steadily with age [5]. Sarcopenia, the loss of muscle strength and mass due to biological aging, is a major cause of functional decline, dependency, and increased risk of falls and fall-related injuries in older adults [6]. Aging also

XSL•FO
RenderX

results in various changes in the human body, including changes in body composition, such as increasing body fat, which is linked to a higher prevalence of chronic diseases such as diabetes, chronic lung disease, cancer, and stroke [6,7].

There is strong scientific evidence that regular physical activity provides extensive health benefits for people aged 65 years and above. In some cases, the evidence of health benefits is greater for older people because the negative outcomes associated with inactivity are more common in this age group than in younger individuals [8]. In 2020, the World Health Organization (WHO) updated its recommendations for sedentary behavior and physical activity for children and adolescents, adults, and older individuals.

According to these recommendations, an individual should engage in 150 to 300 minutes of moderate-intensity physical activity, 75 to 150 minutes of vigorous-intensity physical activity per week, or a combination of both [9]. Additionally, individuals are advised to participate in muscle-strengthening exercises targeting all major muscle groups at least twice a week. These recommendations highlight the importance of developing an effective program to promote physical activity for health-related purposes to reduce the risk of chronic illnesses, falls, injuries, morbidity, and premature mortality [10,11].

Different types of exercise programs have been used in previous studies to increase or maintain physical fitness [12] and body composition [13] in the older adult population. Multicomponent or multimodal exercise, which combines various exercise modalities, such as strength, balance, gait, aerobics, and flexibility, into a single exercise session, has gained increasing attention in recent years for improving the physical function of frail older adults [14-16].

Multicomponent physical exercise programs, particularly strength training, are recognized as the most effective approaches to delay the loss of strength [17,18] and functional disability, and to mitigate adverse effects such as hospitalization. Evidence-based systematic reviews and meta-analyses of randomized controlled trials have shown that multicomponent exercises have a positive impact on muscle mass, strength, balance, and physical performance [19-21]. The integration of multimodal exercise with functional balance and mobility training, moderate- to high-intensity progressive resistance training, and 30- to 45-minute sessions at least twice a week for optimal results is recommended [22].

An additional change that affects older adults, particularly females, is the alteration in postural control, which is influenced by hormonal changes, sarcopenia, osteopenia, and reduced physical activity. Postural imbalances contribute to an increased risk of falls [23]. Multicomponent exercises can help prevent falls by enhancing muscular function and postural control [24]. These exercises are recommended for the older population because they improve postural performance and increase muscle strength and power [25,26].

Although multicomponent exercise programs are known to improve physical function in older adults, most apply standardized protocols, and some studies address postural dysfunctions, such as thoracic kyphosis or forward head posture. Few interventions combine segment-specific training with structured postural education, and individualized progression based on functional assessment is rarely implemented. To address this gap, we developed a multisegmental individual-based exercise program (MIBEX), an equipment-free, cost-effective intervention that targets specific anatomical segments related to postural control, integrates postural correction strategies, and adjusts intensity and complexity weekly according to each participant's needs. The objective was to assess its effects on balance, posture, and functional mobility in community-dwelling older adults. We hypothesized greater improvements in postural alignment and balance with this program compared to postural education alone.

Methods

Study Design

This was a 2-arm parallel design, single-blinded, single-center randomized controlled trial approved by the Ethical Committee of Riphah International University (RCRS-RE-PHD-RS/Fall19/127). The trial was registered at the Iranian Registry of Clinical Trials (trial ID IRCT20221005056094N1). The date of registration was October 25, 2022. All participants signed written informed consent before participating in the study. The participants were also informed that the study intervention had no disadvantages or risks. Careful monitoring of the participants was performed throughout the study, and necessary medical care was provided to the participants when needed. The participants were also informed that they could withdraw freely. During the entire study process, the identities of the participants were not disclosed in any publication of this study. The patient may choose not to participate in the study and withdraw their consent to participate at any time and will not be penalized in any way if they choose not to participate or withdraw from this study. The study was conducted according to CONSORT (Consolidated Standards of Reporting Trials) [27], and included the CONSORT checklist (Checklist 1).

Recruitment and Follow-Up Periods

Participant recruitment and all study activities, including follow-up, were conducted between March 2022 and August 2022. The trial comprised a 12-week intervention phase immediately followed by a 12-week no-intervention follow-up period, with final assessments completed in August 2022. All primary and secondary outcomes, including those related to potential benefits and harms, were measured at baseline, during the intervention, post intervention, and at follow-up.

Participants and Study Design

The data were collected at the outpatient department of the University Teaching Hospital, UOL, and in Lahore, Pakistan. A nonprobability convenience sampling technique was used to collect data from the geriatric population. The inclusion criteria were participants aged 65 to 75 years, including both male and female participants; those who could move independently and climb a flight of stairs independently; those who have thoracic kyphosis of 50 degrees or greater; and those who have cognitive function within normal limits, assessed by Mini-Mental State

XSL•FO
RenderX

Examination ≥24. The exclusion criteria were participants who could not maintain balance when standing unassisted; those with diagnosed neurological or vestibular disorders; and those with serious medical conditions that would limit participation in the exercise program, that is, chest pain, myocardial infarction, or cardiac surgery within 6 months. Participants with uncontrolled hypertension and with a history of hip fracture or total hip replacement within the previous 12 months (due to its potential effect on balance and mobility outcomes) and those who used assistive devices for walking (eg, cane or walker) in daily activities were also excluded.

Intervention

The intervention consisted of a 24-week exercise program. The treatment was applied twice weekly for 12 weeks, after which follow-up readings were taken for the next 12 weeks. Data from both the intervention group and the control group were obtained by the researcher at 6 different times: at baseline (T0) for 3 months (T1, T2, and T3), and then for the next 3 months (T4, T5, and T6) for follow-up visits. The details are shown in Table 1.

[a]Mini-BESTest: Mini-Balance Evaluation Systems Test.

Procedure

Overview

Baseline measurements of both groups were taken before treatment via a global postural system (GPS400). The GPS was used to measure postural sway as well as static and dynamic balance. Stabilometric assessment was performed via GPS by asking patients to stand on the platform while the participants stood on the postural analyzer for picture acquisition. The distance of the participant from the specific acquisition device was predetermined, and it was an essential requirement. Measurements were carried out on each acquired image, which was saved for future use. Postural sway was measured while the participants stood on a force platform for a 20-second period. This platform measured the displacement of the center of pressure (COP; sway path). Pictures were then taken first with the eyes open and then with the eyes closed. The participants were then asked to move on the platform to measure their dynamic balance. After the initial testing, the participants participated in 1-hour exercise sessions twice weekly for 12 weeks.

The exercise program was divided into 6 sections. Exercises were focused on improving balance, mobility, flexibility, strength, and endurance, as well as providing postural education. To implement the program, the experimental group was supervised at all times by 2 physical therapists who were blinded to which older individuals were in each of the groups. The intensity and complexity of exercises were initially prescribed based on each participant's baseline assessment. Adjustments were made weekly using the rating of perceived exertion (Borg scale) to ensure exercises remained challenging yet safe for all participants. The participants were divided into 2 groups.

Group A (Control Group)

Participants in the control group received postural education delivered twice weekly by a physiotherapist in small groups, with each session lasting 30 - 45 minutes. The sessions used a postural correction video demonstrating proper sitting, standing, and walking posture, as well as exercises to improve body alignment during daily activities. Participants were encouraged to practice the demonstrated postures at home, and the sessions were reinforced with visual aids and *reminders* to ensure adherence. This component aimed to increase awareness of correct posture and support balance and functional performance, complementing the primary outcomes of the study. The postural education program administered to participants in the control group is described in Textbox 1.

XSL•FO
RenderX

Textbox 1. Description of the control group.

Component

- Postural education (control group)

Description

- Proper sitting, standing, and walking posture; exercises to improve body alignment

Frequency and duration

- Twice weekly; 30 - 45 minutes per session

Delivery method

- Conducted by a trained physiotherapist in small groups of 6 - 8; delivered via postural correction video

Group B (Exercise Group) MIBEX

The participants in this group received an exercise program. In accordance with the recommendations of the American College of Sports Medicine [28], every session consisted of the following exercises:

- Warm-up period (10 min)
- Exercise period (35 min)
- Postural education includes instructions for maintaining the correct posture (5 min)
- Cool-down period of stretching and relaxation exercises (10 min)

Warm-Up Period

It includes range-of-motion exercises for the shoulder, hip, knee, wrist, and ankle.

Exercise Period

It includes the following exercises:

Balance Exercises

Balance exercises for both static and dynamic balance were given to the patients. During the static exercises, the participants were instructed to remain in the same position for 10 seconds. After the samples were allowed to rest, the test was repeated 3 times. In the case of dynamic exercises, participants performed different exercises under different conditions that challenged their balance by demanding postural corrections. The exercises were also repeated 3 times.

Strengthening Exercises

Muscle-strengthening training consists of exercises for both the upper and lower limbs:

- Sets and repetitions: The participants performed from one set of 5 to 8 repetitions in the first training session to three sets of 10 to 12 repetitions at the end of the program.
- Intensity and progression: The intensity increased with increasing weight from 0.5 to 1.0 kg, and weight progression was determined at the individual level by the therapist.

Stretching and Flexibility Exercises

The upper limb (neck circles, shoulder circles, triceps stretch, pectoralis major stretch, and trapezius stretch) and the lower limb (quadriceps stretch, calf stretch, hamstring stretch, and back stretch) were used.

Endurance Exercises

These included brisk walking and running, starting first at a slow pace and then gradually increasing the intensity.

Postural Education

Postural education included instructions for maintaining the correct posture (5 min).

Cooling Down Period

The cool-down period consisted of stretching and relaxation exercises (10 min), and a progressive approach was used in all the multicomponent exercises.

A progressive approach was used in all the multicomponent exercises. On the basis of a gradual increase in training volume, sets, and repetitions, we intended to gradually include participants with a variety of different exercise levels.

A detailed description of the exercise program is given in Table 2.

XSL•FO
RenderX

Table . Detailed description of the multisegmental individual-based exercise program.

Exercise protocol	Description of exercises	Duration (min)	Intensity or progression
Warm-up period	• ROM[a] exercises for hip, knee, ankle, shoulder, and wrist	10	• Continue as such for 24 wk
Stretching exercises	• Upper limb: Neck circle, shoulder circle, triceps stretch, pectoralis major stretch, trapezius stretch • Lower limb: Quadriceps stretch, calf stretch, hamstring stretch, and back stretch	10	• Week 1 - 4: 5 min • Week 5 - 8: Continue above • Week 9 - 12: 10 min • Week 13 - 24: Continue above
Strengthening exercises	• Bicep curl, triceps curl, hip extension, hip flexion, hip abduction, and knee extension	10	• Week 1 - 4: 8 reps×2 sets, intensity 65% of 1 RM[b] • Week 5 - 8: 10 reps×3 sets, intensity 75% of 1 RM • Week 9 - 12: 12 reps×3 sets, intensity 85% - 90% of 1 RM • Week 13 - 24: Maintain above
Endurance exercises	• Brisk walk, running, and jogging (individualized; low-impact alternatives such as slow-paced walking if needed)	10	• Week 1 - 4: 10 min at comfortable speed • Week 5 - 8: 5 min warm-up, then increase speed for remaining duration • Week 9 - 12: 10 min at increased speed • Week 13 - 16: 15 min at maximum tolerated speed or intensity
Balance exercises	• Heel raises, 1-leg stand, toe raises, sit-to-stand, marching (hold each for 10 s)	10	• Week 1 - 4: 2-hand support • Week 5 - 8: 2-hand support • Week 9 - 12: 1-hand support • Week 13 - 24: No support
Postural education	—[c]	5	• Twice weekly
Cool-down period	• Stretching and relaxation exercises	5	• Continue as such for 24 wk

[a]ROM: range of motion.

[b]RM: repetition maximum.

[c]Not applicable.

Outcome Measures

Four primary outcome measures were used to evaluate the effects of the MBIEX intervention.

Postural Sway

Postural sway refers to the continuous, small movements of the body's COP during quiet standing, reflecting postural stability and balance control. In this study, postural sway was assessed using the GPS**,** which measures the quantitative measure of overall body sway [29]. Measurements were conducted under eyes-open and eyes-closed conditions while participants stood in a comfortable upright position. Lower sway values indicate greater postural stability and better balance control. The GPS system provides reliable and objective measurements, enabling accurate assessment of subtle changes in postural control [30]. Recent studies have reported good test-retest reliability for COP measures obtained via force platforms (intraclass correlation coefficient, ICC=0.85 - 0.95), supporting the use of GPS in clinical and research settings. Postural sway is widely used as a sensitive outcome to evaluate the effectiveness of interventions aimed at improving balance and reducing fall risk in older adults [31].

Timed Up and Go Test

This test was developed by Podsidalo and Richardson [32]. The functional mobility of independent people was evaluated via the Timed Up and Go (TUG) test. A stopwatch was used to record the time it took to stand from a chair, walk a 3-meter distance at the usual speed, turn around, and sit down again. Timing began when the instructor gave the command to go and ended when the participant returned to the starting position. The TUG test has excellent test-retest reliability (ICC=0.97) [33]. A TUG performance of less than 20 seconds indicates mobility

XSL•FO
RenderX

independence, whereas a performance of more than 30 s indicates dependence [34].

Mini-Balance Evaluation Systems Test

The biomechanical constraints, stability limits or verticality, anticipatory postural adjustments, postural responses, sensory orientation, and stability in gait subsystems of the 6 subsystems that underlie static and dynamic balance are covered by the 14 items of the Mini-Balance Evaluation Systems Test (Mini-BESTest), a clinical assessment tool for measuring balance. The Mini-BESTest's test-retest reliability for people with a range of neurological conditions and balance issues has also been demonstrated to be outstanding (ICC=0.92-0.97) [35]. The maximum score on the 14-item Mini-BESTest, which is graded from 0 to −2, is 28. Only the lower scores for items 3 (single-leg stance) and 6 (compensatory lateral stepping) were used when the overall score was calculated. For item 14, the score should be reduced if a person's gait slows by more than 10% between the TUG with and without a dual task [36].

Tragus-to-Wall Test

It is a reliable test of forward-flexed posture in healthy younger (20 - 30 y) and older (>60 y) adults. The patient stood with their feet separated by the length of the individual's foot; heels 10.0 cm from the wall, and buttocks and posterior thorax against the wall; head looking straight ahead: level being horizontal between the bottom of the nose and the tragus. The distance between the posterior aspect of the tragus and the wall was measured with a ruler [37].

Sample Size

The study sample size was estimated on the basis of the mean and SD reported by Szturm et al [38] for the balance scale. An open-source online calculator (OpenEpi V.3.00) was then used to estimate the total sample size as 91 patients. To account for potential attrition, an anticipated dropout rate of 20% was incorporated, consistent with rates reported in previous longitudinal exercise intervention studies involving older adults [39]. This adjustment was made to minimize the risk of reduced statistical power due to participant loss from health-related issues, personal circumstances, or loss to follow-up. Accordingly, the final estimated sample size was 113 patients, with 56 allocated to the experimental group and 57 to the control group. A 95% CI (α) and 80% power were used in the calculation.

Randomization and Blinding

Participants were recruited using convenience sampling and randomly assigned to 1 of 2 groups using the simple lottery method. Each participant was given a unique identification number by the principal investigator, which was written on identical slips of paper and sealed in opaque envelopes. These envelopes were thoroughly mixed and placed in a box. A research assistant—independent of the recruitment, treatment, and assessment process—randomly drew envelopes to assign participants to either group, thereby ensuring allocation concealment and maintaining a 1:1 ratio between groups.

Due to the nature of the interventions, blinding of the participants and treating therapists was not feasible. However, to minimize detection bias, the outcome assessor remained blinded to group allocation throughout the study. Additionally, the data provided to the statistician were anonymized and coded (eg, as group A and group B) to ensure blinding during analysis.

Statistical Analysis

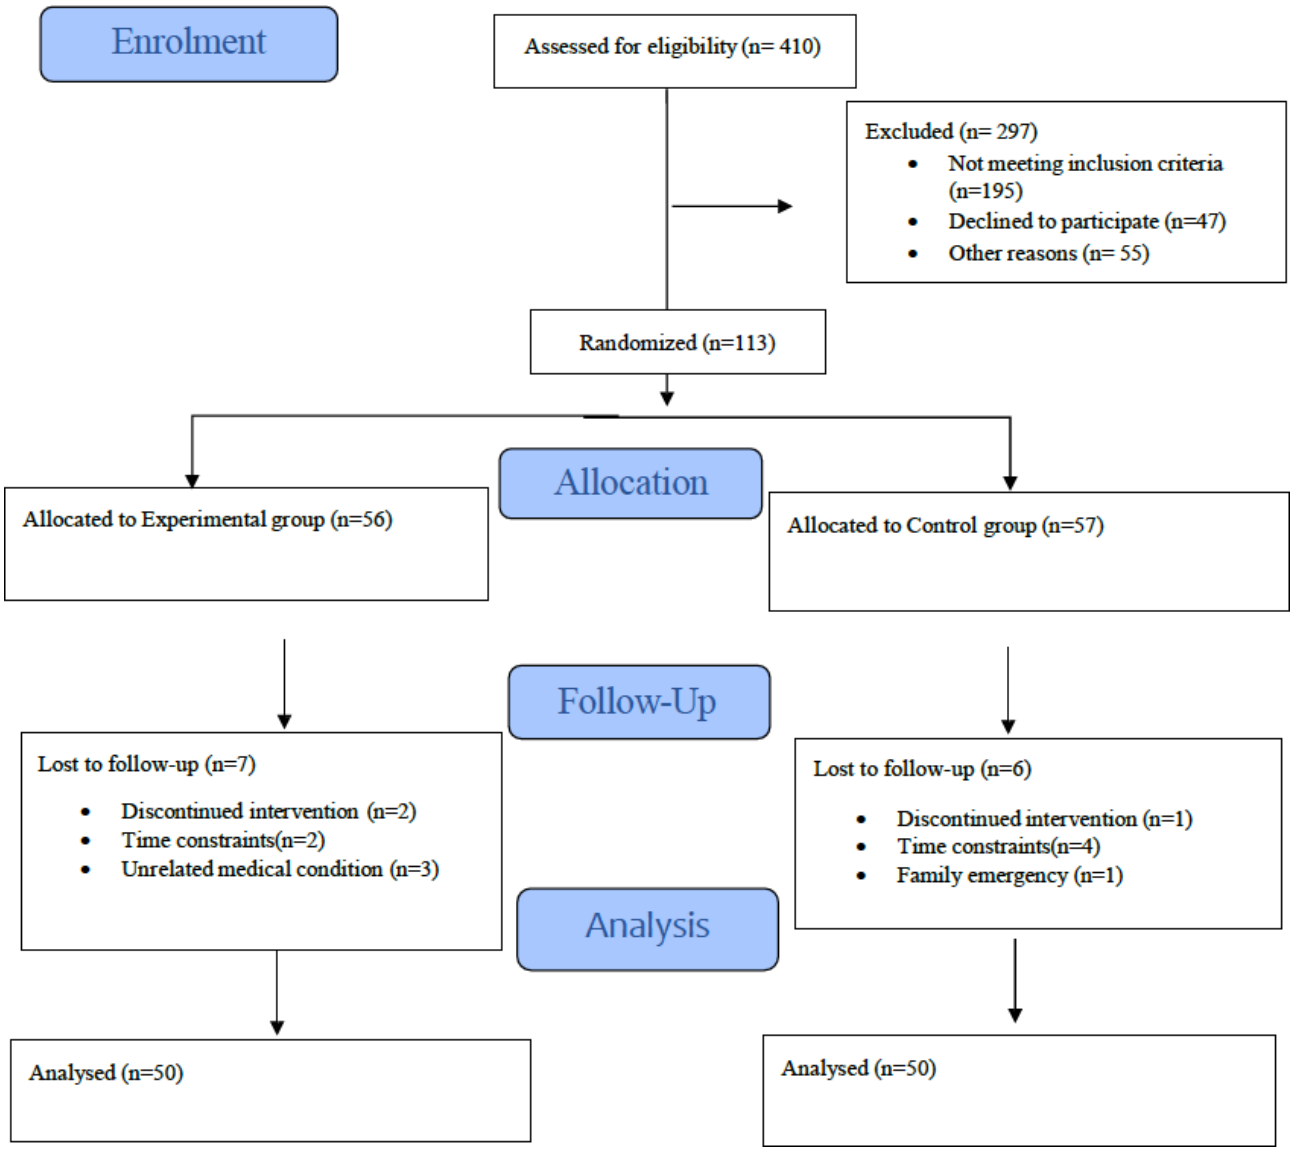
All statistical analyses were performed using SPSS version 26 (IBM Corp.). Continuous variables such as age, weight, and height were reported as mean (SD). The normality of the data was checked with the Kolmogorov-Smirnov test. For comparisons between groups at each time point (baseline, 3 mo), we used the Mann-Whitney *U* test. For within-group changes over time (eg, baseline vs 3 mo), we applied the Wilcoxon Signed-Rank Test. When more than 2 time points were compared within a group, we first ran the Friedman test, followed by pairwise Wilcoxon tests with Bonferroni correction to adjust for multiple comparisons. In addition to *P* values, effect sizes (*r*) were calculated for all nonparametric tests using the formula $r=Z/\sqrt{N}$ (n=number of observations in the test), along with 95% CIs for *r* to provide an estimate of the magnitude and precision of effects. Statistical significance was set at $P<.05$.

Ethical Considerations

The study was approved by the Ethical Committee of Riphah International University (RCRS-RE-PHD-RS/Fall19/127). All participants signed written informed consent before participating in the study. The subjects were also informed that the study intervention had no disadvantages or risks. Careful monitoring of the participants was performed throughout the study; necessary medical care was also provided to the participants when needed. During the entire study process, the identities of the participants will not be disclosed in any publication of this study. The patient may choose not to participate in the study and withdraw their consent to participate at any time and will not be penalized in any way if they choose not to participate or withdraw from this study. All the participants participated voluntarily in the study.

Completed personal data or other documents containing protected personal health information were kept in a locked file at the principal investigator's office. The data were entered into an electronic deidentified database by authorized study team members and checked for completeness and accuracy. Access to data with identifiers was restricted to authorized study team members and authorities. The electronic data were kept on a server regulated by the local research institute. Data will be destroyed 10 years after the study's finalization or 5 years after the last publication.

Results



Participant Flow and Baseline Characteristics

Figure 1 provides a detailed overview of participant enrollment, allocation, follow-up, and analysis. A screening of 410 healthy older individuals was performed for participation in the study. After the exclusion of 297 participants, 113 fulfilled the inclusion criteria of the study. Fifty-seven participants were allocated to the control group, and 56 were allocated to the exercise group. During the study, 13 participants dropped out,

XSL•FO
RenderX

and 100 participants completed the study for 24 weeks. The overall schematic flow of the patient sample is given in the CONSORT guidelines. There were no statistically significant differences between the groups in terms of demographic or clinical characteristics at baseline.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.

Basic Demographics

Descriptive statistics of gender, age, sex, weight, height, and BMI were included as the means and SDs and are summarized in Table 3.

Table 3 shows that the groups were comparable in terms of gender distribution, age, height, weight, and kyphosis angle, with no statistically significant differences observed (P>.05). A significant difference was noted for BMI, which was slightly higher in the exercise group compared to the control group (P=.04).

XSL•FO
RenderX

Table . Baseline demographics of study participants.

Variables	Control group	Exercise group	*P* value
Gender, n (%)			
Men	11 (22)	12 (24)	.81
Women	39 (78)	38 (76)	.42
Age (y), mean (SD)	70.36 (3.08)	70.34 (2.99)	.97
Height (cm), mean (SD)	181.0 (14.0)	178.0 (15.0)	.29
Weight (kg), mean (SD)	71.52 (5.36)	72.34 (6.01)	.47
BMI (kg/m²), mean (SD)	25.42 (1.30)	25.99 (1.38)	.04
Kyphosis (°), mean (SD)	51.90 (4.83)	50.78 (5.20)	.27

Table 4 summarizes the between-group comparisons of all primary outcome measures using the Mann-Whitney *U* test. The exercise group demonstrated significantly greater improvements than the control group in TUG (*U*=161.00; *P*<.001; *r*=0.65, 95% CI 0.45 - 0.80), tragus-to-wall test (TWT; *U*=654.00; *P*<.001; *r*=0.52, 95% CI 0.30 - 0.70), Mini-BESTest (*U*=560.00; *P*<.001; *r*=0.48, 95% CI 0.25 - 0.66), and postural sway (*U*=480.00; *P*=.002; *r*=0.40, 95% CI 0.18 - 0.58). The magnitude of effect sizes suggested a moderate-to-large effect of the intervention on mobility and balance outcomes.

Table . Comparison of outcome measures between the groups.

Outcome measure and groups	Baseline, median (IQR)	Postintervention 1, median (IQR)	Postintervention 2, median (IQR)	Postintervention 3, median (IQR)	Mann-Whitney *U*	*P* value	Effect size, *r* (95% CI)

[b]Not applicable.

[c]TWT: tragus-to-wall test.

[d]Mini-BESTest: Mini-Balance Evaluation Systems Test.

Table 5 presents the within-group changes in functional performance and postural control outcomes for the exercise and control groups across baseline, month 1, month 2, and month 3 assessments. Both groups demonstrated statistically significant improvements in TUG, TWT, Mini-BESTest, and postural sway (*P*<.001 for most outcomes), with the exercise group showing larger effect sizes (*r*=0.71 - 0.80) compared to the control group (*r*=0.40 - 0.70). The exercise group exhibited the greatest gains in mobility and balance measures. Table 5 shows between-group comparisons of all primary outcome measures using the Mann-Whitney *U* test. At postintervention 3, the exercise group performed significantly better than the control group on the TUG test (median 10, IQR 8-12 vs 12, IQR 10-14 seconds; U=161.00, *P*<.001; *r*=0.65, 95% CI 0.45-0.80), TWT (49, IQR 44-54 vs 37, IQR 31-43 cm; U=654.00, *P*<.001; *r*=0.52, 95% CI 0.30-0.70), Mini-BESTest (27, IQR 24-30 vs 18, IQR 16-21 points; U=560.00, *P*<.001; *r*=0.48, 95% CI 0.25-0.66), and postural sway (2.2, IQR 1.8-2.6 vs 2.8, IQR 2.4-3.3 cm;

XSL•FO
RenderX

U=480.00, *P*=.002; *r*=0.40, 95% CI 0.18-0.58). These findings suggest moderate-to-large intervention effects for mobility and balance outcomes. These results indicated that the MIBEX effectively enhanced postural stability and functional mobility over the intervention period.

Table . Comparison of outcome measures within the group.

Outcome measure and groups	Baseline, median (IQR)	Month 1, median (IQR)	Month 2, median (IQR)	Month 3, median (IQR)	*P* value	Wilcoxon *z*-score	Effect size (*r*)	95% CI for change

[a]Mini-BESTest: Mini-Balance Evaluation Systems Test.

[b]Not applicable.

Adherence to the Intervention

Adherence to the intervention was tracked using attendance logs maintained by the treating physiotherapist. Participants were encouraged to attend at least 75% of scheduled supervised sessions over the 12-week intervention period, followed by a 12-week follow-up (no adherence data were collected during the follow-up). Adherence rates for both groups during the 12-week intervention period are presented in Table 6. The intervention group maintained high attendance (92% at wk 4% and 87% at wk 12), whereas the control group's adherence declined from 78% to 70% over the same period.

Table . Adherence rates for the intervention and control groups over the 12-week supervised intervention period.

Time point	Intervention group (%)	Control group (%)
T1 (wk 4)	92	78
T2 (wk 8)	89	74
T3 (wk 12)	87	70

Adverse Events

Adverse events were monitored throughout the intervention period by the treating physiotherapist and during each exercise session. Participants were instructed to promptly report any discomfort, injury, or health-related incidents at any time during the study. No adverse events were reported by participants in either the experimental group or the control group during the study period.

Discussion

Principal Findings

This study focused on assessing the impact of a multisystemic exercise program on the physical function of community-dwelling older adults. This study revealed that a multisystemic exercise program, including low-to-moderate intensity resistance, cardiorespiratory, balance, strength, and flexibility training, along with postural education and an increase in moderate-to-vigorous intensity exercise performed twice a week for 24 weeks, significantly improved physical function and reversed the decline in function associated with aging. These

XSL•FO
RenderX

findings support the original hypothesis that an exercise intervention positively and substantially affects physical fitness in community-dwelling older adults.

The participants in this community-based exercise program achieved considerable gains in multiple functional capacities with minimal investment in equipment compared with conventional strength and/or cardiorespiratory training using costly devices [6]. The improvements were similar to those reported in a recent review of 28 studies on resistance training [40]. Consequently, multicomponent exercise programs may be beneficial, as there is a clear connection between high physical activity and low sedentary behavior, as well as improved muscle strength in physically active older adults [41]. Meta-analyses of recent research have shown that multicomponent exercise programs effectively enhance various aspects of health-related physical fitness [14,38].

The multicomponent exercise program significantly improved lower and upper limb strength. This improvement is likely due to the stimulus provided by the exercise program and the adherence to the exercise prescription guidelines [42]. As participants perform strength exercises, they place demands on their muscles, which stimulates muscle fibers and leads to an increase in muscle strength. Progression training increased over the 24 weeks during which participants performed more upper limb and lower limb exercises. These findings align with those of the Beck Jepsen et al study [43], and they support the results of a recent meta-analysis that emphasized the importance of multiple sets in producing benefits in muscle strength [44].

A systematic review of randomized clinical trials with frail older patients revealed conflicting data regarding improvements in the risk of falls, mobility, balance, strength, functional capacity, and body composition [45]. Even among those who showed improvements in functional capacity, attributing the success of these results to a specific element of the intervention protocol is not appropriate.

In addition, multiple systematic reviews have shown that the multicomponent training regimen, comprising sessions that last 30 to 45 minutes and are conducted 3 times per week, is the most commonly recommended protocol for exercise among frail older adults [46]. Specifically, multicomponent exercise programs that incorporate resistance, balance, and flexibility exercises are highly effective for this population [41,42]. Our study is consistent with these findings, as we used 60-minute exercise sessions twice weekly for a 24-week duration. A year ago, a study in which a TWT was used to measure the altered angle was conducted to investigate the effects of exercise programs on age-related kyphosis. A comparison of the preintervention and postintervention values of the occiput-to-wall test revealed a significant difference after the protocol was administered (P<.001) [43], similar to our study's results. Multicomponent exercise programs delivered in primary health care settings have been shown to improve postural control and muscle power in older adults, potentially helping to prevent falls and enhance quality of life, as demonstrated in a study with a similar design to ours conducted on healthy older individuals. The sample size of that study was small, with participants averaging 60 years of age [24].

The main strength of our study is that it uses a multicomponent exercise program (MIBEX), which appears to be a feasible, efficient, and cost-effective option for promoting physical activity among older adults in primary health care settings. This is because the exercises can be performed in groups, require inexpensive equipment, and can be modified to suit local characteristics. Additionally, our study uses a personalized exercise program tailored to individual characteristics and includes postural education.

This study had several limitations. First, it was not possible to blind participants, clinicians, or trainers in this type of exercise program. Although the outcome assessors were blinded to the groupings, some participants may have inadvertently revealed their treatment status, which could have affected the results. This study used a postural teaching program via video for the control group. However, there was no significant difference in the outcome measures since participants did not adhere to the activity, leading to a low rate of participation in the exercise sessions. Despite frequent stimulation and customized work, program adherence fell short of expectations.

Moreover, participation was entirely voluntary, and the main cause for exclusion was when participants refused to participate. As a result, the majority of participants may have established a positive relationship between exercise and health, which could have led to bias. Additionally, we could not determine whether participants who declined to participate would have benefited from physical activity as well.

Future studies should specifically consider the effects of exercise programs on physical performance by gender. Evidence suggests that older women may experience greater declines in physical function and show less pronounced improvements in strength and balance following exercise interventions compared to men [47]. Therefore, future research should account for sex as an important factor when designing and evaluating exercise programs, and may consider including balanced numbers of male and female participants to better assess gender-specific responses.

The current findings can be used to plan and implement future useful public health interventions for community-dwelling older individuals, which could reduce prospective healthcare expenses associated with disabilities among this population. Additionally, primary health care programs should aim to minimize barriers to physical activity promotion. Although recommendations from the literature should be considered in exercise programs for older adults, they may occasionally create barriers to the development of interventions. Nonetheless, socialization and recreational activities seem to be essential components in enhancing adherence among older adults and should be incorporated into multicomponent exercise programs.

Conclusion

The 24-week tailored exercise program had significant positive effects on improving physical function in older adults. The participants exhibited marked improvements in strength, flexibility, balance, and endurance, leading to better daily performance, increased mobility, and a reduced risk of falls. The personalized nature of the program ensured higher

XSL•FO
RenderX

adherence rates and more meaningful outcomes, addressing various aspects of physical function for overall health and well-being.

Abstract

Background: Age-related cognitive decline can threaten independence in older adults, creating an urgent need for effective and practical preventive strategies. Nonpharmacological approaches such as physical activity, cognitive stimulation, and combined programs show promise, but their comparative effectiveness and the specific cognitive domains they influence are not yet clearly established.

Objective: This study evaluated the effects of 3 nonpharmacological interventions. These consisted of a physical activity program using Zumba, a video game–based cognitive stimulation program, and a combined physical and cognitive program. The aim was to determine their effects on global cognition and specific cognitive domains in community-dwelling older adults in the Klang Valley of Malaysia. A secondary objective was to examine the influence of adherence on cognitive outcomes.

Methods: A total of 96 participants (median age 69 y, IQR 65-72 y; n=63, 65.6% female) were assigned to 4 groups: physical (n=12), cognitive (n=23), combined (n=43), and control (n=18). Global cognitive performance was measured using the Montreal Cognitive Assessment at baseline and postintervention. Mixed ANOVA examined time and time × group effects. Additional nonparametric analyses (Kruskal-Wallis, Mann-Whitney *U*, Wilcoxon signed rank tests) were conducted under intention-to-treat and per-protocol (PP) frameworks. Adherence was defined as attending 50% or more of scheduled sessions, with PP analyses reclassifying participants accordingly.

Results: Global cognition improved significantly over time across all groups (time main effect: $F_{1,92}$=7.03, P=.008; time × group interaction: $F_{3,92}$=0.57, P=.64). PP analyses showed moderate gains for participants attending 50% or more of cognitive sessions (r=0.46) and larger gains for those adhering to the combined intervention (r=0.66), with median Montreal Cognitive Assessment scores increasing by approximately 2 points in both adherent groups. Subdomain analyses indicated improvements in language (all groups), visuospatial function (combined group), and orientation (cognitive group).

Conclusions: All intervention types were associated with improvements in cognitive performance over time, with comparable gains across groups. Participants who achieved at least moderate adherence (≥50%) to the cognitive or combined interventions demonstrated larger and more consistent within-group effect sizes, highlighting the importance of sustained engagement. These findings support the feasibility and potential cognitive benefits of structured, multimodal nonpharmacological interventions for community-dwelling older adults.

Introduction

Malaysia is rapidly becoming an aging society. The proportion of the population aged 60 years and older is projected to increase from 11.6% in 2024 to 17.3% by 2040, surpassing the 15% threshold commonly used to define an aging population [1]. This demographic transition reflects a global trend, as many high- and middle-income countries face similar shifts toward older age structures [2]. Based on these projections, Malaysia will officially be classified as an aging society by 2040.

Globally, the prevalence of mild cognitive impairment (MCI) has been estimated at 19.7% among individuals aged 50 years and older [3]. In Malaysia, previous studies have reported even higher estimates, with approximately 21.1% of older adults affected [4,5]. More recently, a study conducted in Kuantan, Malaysia, found the prevalence of MCI among adults aged 60 years and older to be 18.7% [6]. Despite these substantial prevalence rates, most individuals remain undiagnosed until later stages of cognitive decline, with only 8% of those in the early stage of MCI receiving a formal diagnosis [7]. These findings have important implications for independence, health care use, and caregiver burden, contributing to the rising societal impact of dementia [8].

Lifestyle-based interventions are increasingly recognized as promising strategies for delaying cognitive decline, particularly given the limited effectiveness of pharmacological treatments [9]. Aerobic exercise has been associated with improvements in brain structure and function through mechanisms such as enhanced cerebral blood flow and improved regulatory effects on the brain. Sustained aerobic exercise increases heart rate, boosts cerebral perfusion, and promotes glucose metabolism in the brain [10]. Among the various modalities, Zumba represents a culturally engaging form of exercise that combines rhythm, coordination, and social interaction. Participation in Zumba classes has been shown to improve quality of life and visuospatial memory among older adults [11,12]. Zumba has been proposed as a feasible public health strategy due to its enjoyable and socially engaging nature [13], and its increasing popularity within Malaysian community settings further underscores its potential for broader implementation.

Parallel to this, technology-driven cognitive training programs, including video game–based interventions, have emerged as scalable and accessible tools for older adults. Evidence from computerized and video game–based cognitive training indicates that overall effects on cognitive performance in healthy older adults are positive but small. Reported benefits vary substantially across cognitive outcomes and are strongly influenced by intervention design characteristics, including delivery format and training intensity [14]. Improvements in specific domains are inconsistent, and transfer to global cognition remains variable, underscoring the importance of task design and intervention structure. With increasing digital literacy among urban-dwelling Malaysian older adults, including those in the Klang Valley, such approaches are becoming increasingly feasible.

Emerging research suggests that combining physical and cognitive interventions may have synergistic effects, as aerobic exercise provides a neurophysiological foundation for plasticity, while cognitive training directly stimulates neural networks [15]. However, studies directly comparing these approaches, particularly in Asian populations, remain limited.

The present semirandomized controlled trial was designed to address these gaps in the Malaysian context. Older adults living in the Klang Valley were allocated into physical activity (Zumba), cognitive stimulation (video game), combined intervention, or control groups within community settings. This study evaluated the effects of the interventions on global cognitive function using the Montreal Cognitive Assessment (MoCA). We also explored changes across cognitive subdomains, examined whether attendance influenced outcomes, and identified participants who demonstrated meaningful improvements, defined as achieving the minimal clinically important difference of a ≥2-point increase in MoCA scores [16]. Thus, this study aimed to evaluate the effects of Zumba, video game–based cognitive stimulation, and combined interventions on global cognitive function among older adults in Klang Valley, Malaysia, and to examine the influence of adherence on cognitive outcomes, with the hypothesis that the combined intervention would produce the greatest improvements.

Methods

Study Design and Setting

This semirandomized controlled trial was conducted as part of the ongoing MyAgeWell project, which investigates lifestyle-based strategies to promote cognitive health among older adults in the Klang Valley, Malaysia. A total of 400 community-dwelling adults aged 60 years or older completed baseline assessments within the MyAgeWell cohort. Participants were recruited from senior centers and residential communities across the Klang Valley [17,18].

Of these, a subset was invited to participate in the present 6-month intervention trial based on willingness to engage in structured intervention sessions, availability during the intervention period, and feasibility considerations specific to the intervention modalities (eg, access to internet-enabled devices for online cognitive sessions). Individuals who did not meet these requirements or declined participation continued in the observational cohort but were not enrolled in the intervention trial.

XSL•FO
RenderX

Eligible participants were allocated to 1 of 4 groups (Zumba, video game–based cognitive stimulation, combined intervention, or control group) using a semirandomized (quasi-randomized) allocation approach. Participants were primarily assigned in a sequential cycle to maintain approximate balance in group sizes. Minor adjustments were made in 24% (23/96) of participants to accommodate the logistical feasibility of intervention delivery. No allocation concealment was implemented, and neither participants nor outcome assessors were blinded to group assignment. All intervention arms shared identical eligibility criteria, and group assignment differed only by allocation procedure rather than differential enrollment criteria.

This trial evaluated the effects of weekly physical exercise (Zumba), video game–based cognitive stimulation, and a combined intervention over 6 months, with outcomes assessed both between groups (relative to a control group) and within groups (preintervention and postintervention).

Participants

Eligible participants were cognitively normal or without cognitive impairment, including those with well-managed medical conditions such as hypertension. All participants were required to have some mobility, defined as the ability to walk at least 3 m independently, and to be able to communicate in at least 1 of the following languages: English, Malay, Mandarin, or Tamil.

Individuals were excluded if they had a diagnosis of neurodegenerative diseases such as Alzheimer or Parkinson disease, psychiatric disorders, uncorrected hearing or vision impairments, or were currently taking psychiatric medications. Participants who were immobile, required full-time caregiver assistance, or had comprehension difficulties that could interfere with study assessments were also excluded.

Ethical Considerations

All procedures were explained to the participants, and written informed consent was obtained from all participants before study participation in accordance with the Declaration of Helsinki. The study was approved by the Sunway University Research Ethics Committee (SUREC2020/039) and registered at ClinicalTrials.gov (NCT06376656). Participant privacy and confidentiality were protected throughout the study, and all collected data were deidentified prior to analysis. Participants were informed of the study procedures, potential risks, and their right to withdraw at any time without penalty. Participants received cash compensation of RM 50 (US $12.09) for baseline and postassessment completion, RM 30 (US $7.25) per physical intervention session, and RM 10 (US $2.42) per online cognitive intervention session.

Sample Size Considerations

This study included all eligible participants from the ongoing MyAgeWell cohort who consented to join the 6-month intervention. No formal a priori power calculation was performed, and the sample size was determined by feasibility and participant availability within the study timeline.

Intervention Procedures

Adherence Assessment and Per-Protocol Classification

No participants withdrew during the 6-month intervention, and complete MoCA data were available for all participants. Per-protocol (PP) groups were defined post hoc by applying an adherence threshold of ≥50% attendance calculated across the full 6-month intervention period for each intervention component. Participants not meeting this threshold were assigned to the control or low-adherence PP group. No participants were removed, reassigned, or reallocated during the intervention period based on adherence; all reclassifications occurred analytically at the PP stage.

Zumba Exercise

The Zumba intervention was delivered in 19 weekly sessions of approximately 60 minutes each at View Gallery, an activity space at Sunway University. The sessions were low impact, culturally adapted, and designed to emphasize coordination, flexibility, balance, and moderate-intensity aerobic activity. All sessions were led by certified instructors trained in working with older adults. Attendance was carefully recorded to monitor adherence.

Video Game–Based Cognitive Stimulation

The video game–based cognitive intervention consisted of 24 weekly online sessions delivered via Zoom, each lasting 60 minutes. Participants were asked to download and use the video games on their personal devices (Android or iOS). Two commercially available games were used: Tetris, developed by Alexey Pajitnov, targeting visuospatial reasoning and problem-solving, and Aim Lab, developed by Statespace Inc., designed to train attention, processing speed, and hand-eye coordination. Attendance and performance were monitored via Zoom screen sharing, score reporting, and session time logs. The research team did not develop or own any of the software, did not receive funding or sponsorship from the software developers, and had no other financial or personal relationships with the developers. All potential conflicts of interest are disclosed in the *Conflicts of Interest* section.

Combined Intervention

Participants in the combined intervention group received both physical and cognitive training components. Specifically, participants attended one 60-minute Zumba session per week delivered in person and one separate 60-minute video game–based cognitive stimulation session per week delivered online via Zoom. The 2 sessions were scheduled on different days to reduce fatigue and maximize engagement. Thus, while each intervention component was matched in duration to its corresponding single-modality arm, the combined group received a greater total weekly intervention dose (120 min/wk).

Control Group

Participants in the control group continued with their usual daily routines and did not participate in structured exercise or cognitive stimulation.

XSL•FO
RenderX

Outcome Measures

Cognitive function was assessed using the MoCA before and after the intervention. The MoCA, developed and published in 2005 as a brief cognitive screening tool with high sensitivity and specificity [19], assesses global cognitive function across 7 subdomains: visuospatial or executive function, naming, attention, language, abstraction, delayed recall, and orientation [20]. Both total and subdomain scores were analyzed to determine the magnitude and domain specificity of cognitive changes. Attendance was recorded for all sessions, with adherence calculated as the percentage of sessions attended relative to the total scheduled sessions.

Statistical Analysis

Data were analyzed using IBM SPSS Statistics (version 27). Descriptive statistics summarized participants' demographic characteristics. Normality was assessed using the Shapiro-Wilk test, skewness, and kurtosis. Although MoCA before and MoCA after scores showed mild deviations from normality, the MoCA change score was approximately symmetric (skewness=0.13, kurtosis=0.30, Shapiro-Wilk P=.02), and Levene test indicated homogeneity of variances (P=.15). Given the sample size (n=96) and robustness of ANOVA to mild nonnormality, both parametric and nonparametric analyses were conducted.

A 2-way mixed ANOVA (time × group) was performed to examine changes in MoCA scores from baseline to postintervention across the 4 groups. Kruskal-Wallis and Wilcoxon signed rank tests were conducted as nonparametric sensitivity analyses to confirm the robustness of the findings.

Between-group comparisons of change scores were performed using Kruskal-Wallis tests, followed by Mann-Whitney U tests with Bonferroni correction for pairwise comparisons. Effect sizes were reported as $r=|Z|/\sqrt{N}$ for Wilcoxon and Mann-Whitney U tests and as η^2 for Kruskal-Wallis tests, interpreted as small (0.1), medium (0.3), or large (0.5).

Associations between attendance and MoCA change were examined using Spearman rank correlation. To further explore the predictive value of attendance, multiple linear regression analyses were conducted to assess whether attendance variables significantly predicted changes in MoCA scores. In addition, receiver operating characteristic (ROC) analyses were performed to evaluate the discriminative ability of attendance percentage in identifying cognitive responders (defined as ≥2-point MoCA improvement). Statistical significance was set at P<.05.

Results

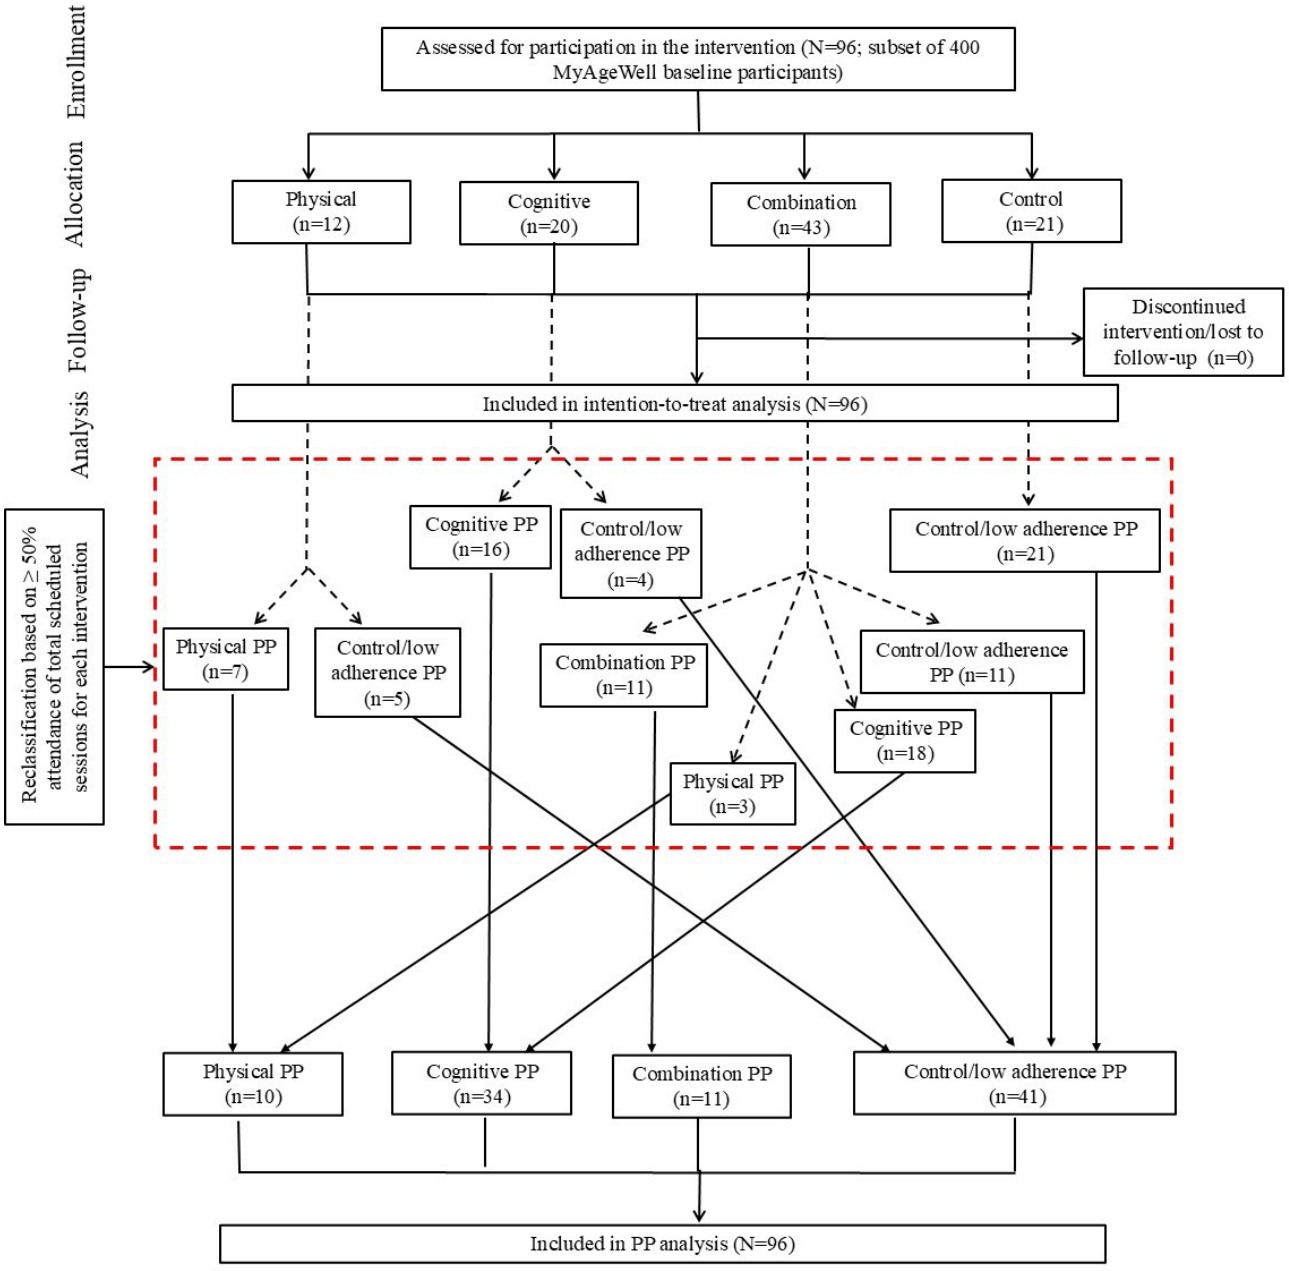
Participant Flow and Group Allocation (Intention-to-Treat and PP Analyses)

Participant Flow Overview

A subset of 96 participants from the MyAgeWell cohort participated in the 6-month intervention involving physical activity (Zumba), cognitive stimulation (video game–based), or combined physical and cognitive stimulation, following selection based on willingness, availability, and intervention-specific feasibility requirements.

Participants were allocated to physical activity (Zumba; n=12), cognitive stimulation (video game; n=20), combination (n=43), and control (n=21) groups (intention-to-treat [ITT] sample, N=96). There were no dropouts during the intervention period and no missing postintervention MoCA assessments. All 96 participants completed preintervention and postintervention MoCA testing and were included in the ITT analyses.

For the PP analysis, participants were reassigned based on actual adherence, using a ≥50% attendance threshold for each intervention. This threshold was chosen as a pragmatic cutoff, representing moderate engagement while retaining an adequate sample size for analysis. Adherence at the ≥50% threshold corresponded to attending at least 10 of 19 Zumba sessions, 12 of 24 cognitive sessions, or both in the combined intervention, with each session lasting 60 minutes weekly. Although higher thresholds (eg, 70% - 80%) [21] are commonly applied in medication adherence and clinical trials as a conservative definition of "good adherence," previous studies on lifestyle and cognitive interventions have reported wide variability in attendance rates, with thresholds ranging from 50% to 80% [22,23]. Sensitivity analyses at higher thresholds in this study showed similar overall patterns but reduced analytic stability. The ≥50% attendance threshold was applied only after completion of the intervention to define analytic PP groups and did not influence intervention delivery or participant participation. Participants who did not meet the ≥50% attendance threshold, including those originally allocated to the control arm and those with partial but insufficient intervention exposure, were classified into a control or low-adherence PP group. Exposure below this level was considered unlikely to produce a meaningful intervention effect.



Movement of Participants From ITT Groups to PP Groups

In the ITT physical group (n=12), 7 participants attended at least 50% of the Zumba sessions and were therefore retained in the physical PP group, while the remaining 5 participants, who attended less than 50%, were reclassified into the control or low-adherence PP group. In the ITT cognitive group (n=20), 16 participants achieved at least 50% adherence to the video game sessions and remained in the cognitive PP group, whereas 4 participants with lower adherence were reassigned to the control or low-adherence PP group. In the ITT combination group (n=43), 11 participants met the adherence threshold for both Zumba and video game components and continued in the combination PP group. From the ITT combination group, 3 participants who adhered only to Zumba were reassigned to the physical PP group, 18 participants who adhered only to the video game component were moved to the cognitive PP group, and the remaining 11 participants, who did not achieve at least 50% adherence to either component, were reassigned to the control or low-adherence PP group. All 21 participants in the ITT control group remained in the control or low-adherence PP group. Following reclassification, the PP sample comprised physical (n=10), cognitive (n=34), combination (n=11), and control or low-adherence (n=41) groups. No participants were excluded from ITT analyses. This detailed reporting clarifies how participants transitioned from their original ITT allocation to the PP groups, ensuring transparency in how adherence

XSL•FO
RenderX

influenced the final analytic samples. Figure 1 illustrates the participant flow diagram (adapted CONSORT [Consolidated Standards of Reporting Trials] for quasi-randomized trial; Checklist 1).

Figure 1. Participant flow diagram (adapted CONSORT [Consolidated Standards of Reporting Trials] for quasi-randomized trial). Of 400 participants who completed baseline assessments in the MyAgeWell cohort, a subset of 96 were enrolled in the present 6-month intervention study and allocated to physical (n=12), cognitive (n=20), combination (n=43), and control (n=21). No participants dropped out, and no postintervention Montreal Cognitive Assessment data were missing. Per-protocol reclassification (dashed red box) was based on ≥50% attendance for each intervention component and produced PP groups of physical (n=10), cognitive (n=34), combination (n=11), and control or low adherence (n=41). The 96 participants were a subset of the larger MyAgeWell cohort (N=400). PP: per-protocol.

Baseline Characteristics

Baseline characteristics were assessed according to the original group allocation. Table 1 presents participants' demographic characteristics and baseline MoCA scores by intervention group. Participants' median age was 69 (IQR 65-72) years and did not differ significantly across groups (Kruskal-Wallis H=0.277, P=.96). MoCA scores at baseline were similar across groups (H=1.131, P=.77), with an overall median of 26 (IQR 25-28). Besides, although female participants comprised a larger proportion of the sample (63/96, 65.6%), no statistically significant differences in sex distribution were observed across intervention groups (χ^2_3=1.684, P=.64). Education level differed significantly across groups (χ^2_{18}=55.632, P<.001) and represents a potential confounding factor given its known association with MoCA performance. The cognitive group had the highest proportion of participants with a bachelor's degree (12/20, 60%), whereas the combination group included a higher proportion of participants with a master's degree (8/43, 18.6%).

MoCA[e] before, median (IQR)	26 (25-27)	26 (24-28)	26 (25-27)	26 (23-29)	26 (25-28)	.77[b]

[a]*P*<.05 was considered statistically significant.

[b]Kruskal-Wallis test for continuous variables (age and MoCA before).

[c]Chi-square test for sex distribution (male + female) across groups.

[d]Chi-square test for categorical variables (education level and hypertension) across groups.

[e]MoCA: Montreal Cognitive Assessment.

Descriptive Statistics and Normality

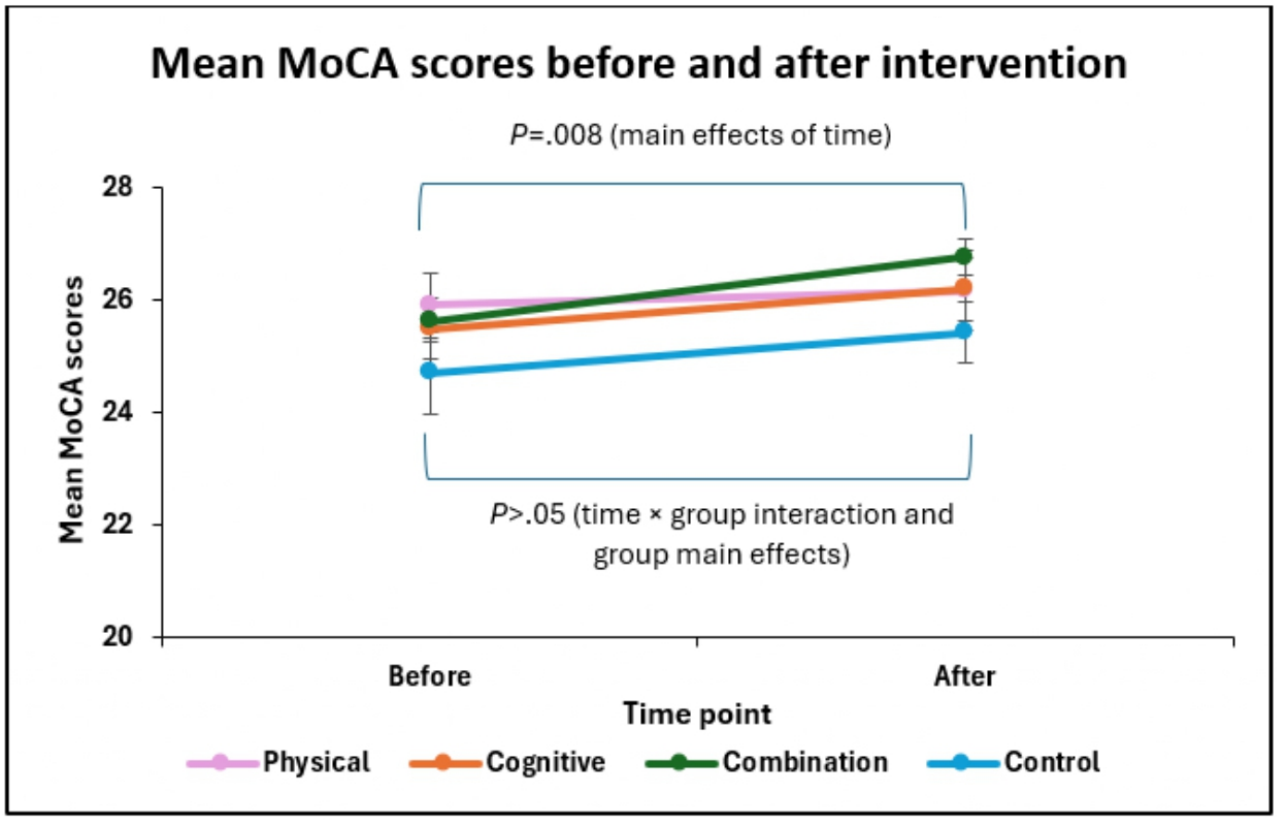
At baseline, participants demonstrated a median MoCA score of 26 (IQR 25-28), with slight negative skew (−0.877) and moderate kurtosis (1.079). The Shapiro-Wilk test indicated significant deviation from normality (*P*<.001), but the distribution was considered suitable for further analysis. Postintervention, the median MoCA score increased to 27 (IQR 26-29), showing moderate negative skew (−1.045) and kurtosis (1.210), with Shapiro-Wilk *P*<.001. The distribution of MoCA change scores (after – before) was approximately normal (mean 0.84, SD 2.30, skewness=0.125, kurtosis=0.304, Shapiro-Wilk *P*=.02), and Levene test confirmed homogeneity of variances across intervention groups (*P*=.15). These results justified the use of both parametric (mixed ANOVA) and nonparametric (Wilcoxon signed rank, Kruskal–Wallis, and Mann-Whitney *U*) analyses.

Mixed ANOVA (Time × Group Effects)

A 2×4 mixed ANOVA was conducted to examine the effects of time (pre vs post) and group (physical, cognitive, combination, and control) on overall MoCA scores (Table 2), with participants analyzed according to their original group allocation (ITT), irrespective of adherence level. The analysis revealed a significant main effect of time ($F_{1,92}$=7.47, *P*=.008, η^2=0.075), indicating that participants demonstrated a significant improvement in cognitive performance from preintervention to postintervention across all groups.

Table . Mixed ANOVA results for global Montreal Cognitive Assessment score.

Effect	Test statistic, *F* (*df*)	*P* value	Effect size (η^2)	Interpretation
Time	7.47 (1, 92)	.008[a]	0.075	Significant main effect
Group	1.28 (3, 92)	.29	0.040	Not significant
Time × group	0.57 (3, 92)	.64	0.018	Not significant



[a] *P*<.05 was considered statistically significant.

However, the time × group interaction was not significant ($F_{3,92}$=0.57, *P*=.64, η^2=0.018), suggesting that the magnitude of cognitive improvement did not differ significantly among the intervention types. Similarly, the between-group main effect

XSL•FO
RenderX

was nonsignificant ($F_{3,92}$=1.28, P=.29, η^2=0.040), indicating no baseline or overall mean differences between the 4 groups. Figure 2 shows the mean MoCA scores for each group before and after the intervention, illustrating a general upward trend across time regardless of intervention condition. Although the combination group showed a numerically larger increase from preassessment to postassessment, the time × group interaction was not significant, indicating comparable improvements across groups.

Figure 2. Mean MoCA scores before and after the intervention across groups. Data represent group mean (SEM). A significant main effect of time was observed ($F_{1,92}$=7.47, P=.008, η^2=0.075), indicating overall improvement in cognitive performance from preintervention to postintervention. The time × group interaction and group main effects were nonsignificant (P>.05), suggesting similar gains across all intervention groups. MoCA: Montreal Cognitive Assessment.

ITT Analysis: Cognitive Outcomes

Within-Group Changes (Wilcoxon Signed Rank Test)

Within-group comparisons of global cognitive performance were assessed using Wilcoxon signed rank tests for each intervention arm. Table 3 presents the preintervention and postintervention MoCA scores, corresponding change values, test statistics, and effect sizes.

Table . Within-group Montreal Cognitive Assessment score changes (intention-to-treat analysis, Wilcoxon signed rank test).

Group	MoCA[a] before, median (IQR)	MoCA after, median (IQR)	Median change	*Z*	*P* value[b]	Effect size (*r*)	Interpretation
Physical (n=12)	26 (25-27)	26 (25-28)	0.00	−0.59	.56	0.17	NS[c]
Cognitive (n=20)	26 (24-28)	26 (24-28)	0.00	−0.94	.35	0.21	NS
Combination (n=43)	26 (25-27)	27 (26-28)	+1.0	−3.55	<.001	0.54	Significant
Control (n=21)	26 (23-29)	26 (25-27)	0.00	−1.22	.22	0.27	NS
Total (N=96)	26 (25-28)	27 (26-29)	+1.0	3.38	<.001	0.34	Significant (overall)

[a]MoCA: Montreal Cognitive Assessment.

[b]P<.05 was considered statistically significant.

[c]NS: nonsignificant.

XSL•FO
RenderX

Across all participants, median MoCA scores increased from 26 (IQR 25-28) at baseline to 27 (IQR 26-29) postintervention, reflecting an overall improvement of +1 points (Z=3.38, P<.001, r=0.34), indicating a moderate effect. Among individual groups, the combination group showed a statistically significant increase in MoCA scores from 26 (IQR 25-27) to 27 (IQR 26-28) (Z=−3.55, P<.001, r=0.54), representing a large effect size. In contrast, the physical (median 26, IQR 25-27 to median 26, IQR 25-28), cognitive (median 26, IQR 24-28 to median 26, IQR 24-28), and control (median 26, IQR 23-29 to median 26, IQR 25-27) groups demonstrated nonsignificant improvements, with small effect sizes ranging from r=0.17 to 0.27. These findings suggest that while general cognitive function improved modestly across the entire sample, the combined physical and cognitive stimulation produced the most meaningful within-group enhancement.

Between-Group Comparisons (Kruskal-Wallis and Mann-Whitney U Tests)

Between-group analyses were conducted to determine whether changes in global cognition (MoCA change scores) differed significantly across intervention groups. The Kruskal-Wallis test showed no significant difference among the 4 groups (H=1.20, P=.75, η^2=0.013), indicating that overall cognitive improvement did not differ meaningfully between intervention types.

Subsequent pairwise Mann-Whitney U tests comparing each intervention group with the control group also yielded nonsignificant results. The physical vs control comparison (Z=−0.208, P=.84, r=0.036), cognitive vs control (Z=−0.026, P=.98, r=0.004), and combination vs control (Z=−0.848, P=.40, r=0.11) all demonstrated small, negligible effect sizes. Taken together, these findings suggest that while participants exhibited within-group improvements over time (Figure 2), the degree of improvement did not significantly differ across intervention conditions (Table 4). Given the small and unbalanced group sizes and the use of nonparametric tests, effect sizes (r and η^2) were reported to indicate the magnitude and direction of effects, formal 95% CIs for these nonparametric effect sizes were not calculated due to limited methodological support and reduced interpretability in small, skewed samples.

Table . Between-group comparisons of Montreal Cognitive Assessment change scores (intention-to-treat analysis).[a]

Comparison	Test statistic	P value	Effect size (r/η^2)	Interpretation
Kruskal-Wallis (4 groups)	H=1.20	.75	η^2=0.013	NS[b]
Physical vs control	Z=−0.208	.84	r=0.036	NS
Cognitive vs control	Z=−0.026	.98	r=0.004	NS
Combination vs control	Z=−0.848	.40	r=0.110	NS

[a]Effect sizes are reported as r or η^2. CIs were not calculated for nonparametric effect sizes due to small and uneven group sizes. P<.05 was considered statistically significant.

[b]NS: nonsignificant.

MoCA Subdomain Analysis (Wilcoxon Within Each Group)

To explore domain-specific cognitive effects, Wilcoxon signed rank tests were conducted for each of the 7 MoCA subdomains within the 4 intervention groups (Table 5). In the physical group, a significant improvement was observed in the language domain (P=.004), whereas other subdomains such as visuospatial, naming, attention, abstraction, memory, and orientation showed no significant changes.

XSL•FO
RenderX

Table . Wilcoxon signed rank test results for Montreal Cognitive Assessment subdomains by group.[a]

MoCA[b] subdomain	Physical (*P* value)	Cognitive (*P* value)	Combination (*P* value)	Control (*P* value)	Interpretation
Visuospatial	.77	.64	.03	.81	Improved only in combination group
Naming	.32	.56	.06	>.99	NS[c] across all groups
Attention	.56	.15	.56	.48	NS across all groups
Memory	.62	.21	.83	.55	NS across all groups
Language	.004	.05	.02	.79	Improved in physical and combination groups; trend in cognitive group
Abstraction	.32	.71	.13	.48	NS across all groups
Orientation	.38	.06	.11	.29	Trend in cognitive group only

[a]*P*<.05 was considered statistically significant.

[b]MoCA: Montreal Cognitive Assessment.

[c]NS: nonsignificant.

In the cognitive group, there were nonsignificant trends toward improvement in language (*P*=.05) and orientation (*P*=.06), suggesting possible subtle gains that did not reach statistical significance. Participants in the combination group demonstrated significant improvements in both visuospatial (*P*=.03) and language (*P*=.02) domains, indicating that combining physical and cognitive activities may yield broader cognitive benefits. In contrast, the control group exhibited no significant changes in any MoCA subdomain across the intervention period.

PP Analysis: Cognitive Outcomes

Overall Group Comparisons

A Kruskal-Wallis test indicated no significant difference in MoCA change scores among the 4 PP groups (H=3.275, df=3, *P*=.35), with a small effect size (η^2=0.034). Although not statistically significant, mean rank trends showed that participants in the cognitive and combination groups tended to exhibit slightly greater improvements compared with the physical and control or low adherence groups.

Within-Group Changes (Wilcoxon Signed Rank Tests)

Within-group comparisons of preintervention and postintervention MoCA scores are presented in Table 6. Significant improvements were observed in the cognitive (Z=−2.693, *P*=.007, r=0.46) and combination (Z=−2.200, *P*=.03, r=0.66) groups, reflecting moderate-to-large effect sizes. An increase of ≥2 points on the MoCA was considered a meaningful improvement. Using this criterion, participants in the cognitive and combination groups demonstrated median gains of +2 points, consistent with the definition of a cognitive responder. The physical (Z=−0.144, *P*=.89, r=0.05) and control or low adherence (Z=−1.468, *P*=.14, r=0.23) groups did not show significant changes. These findings suggest that interventions involving cognitive engagement, either independently or in combination with physical activity, led to more pronounced cognitive benefits.

Table . Within-group changes in Montreal Cognitive Assessment scores by intervention group (per-protocol analysis).

Group	MoCA[a] before, median (IQR)	MoCA after, median (IQR)	Median change	*Z*	*P* value[b]	Effect size (*r*)	Interpretation
Physical (n=10)	26 (25 - 27)	26 (25 - 28)	0.0	−0.144	.89	0.05	NS[c]
Cognitive (n=34)	25 (24 - 26)	27 (26 - 28)	+2.0	−2.693	.007	0.46	Significant
Combination (n=11)	27 (26 - 28)	29 (28 - 30)	+2.0	−2.200	.03	0.66	Significant
Control or low adherence (n=41)	26 (25 - 27)	26 (25 - 27)	+0.0	−1.468	.14	0.23	NS

[a]MoCA: Montreal Cognitive Assessment.

[b]*P*<.05 was considered statistically significant.

[c]NS: nonsignificant.

XSL•FO
RenderX

Between-Group Pairwise Comparisons

Pairwise Mann-Whitney *U* tests comparing each intervention group with the control or low adherence group were nonsignificant (Table 7). Effect sizes were small across all comparisons ($r<0.15$), indicating minimal between-group differences in the magnitude of MoCA change.

Table . Between-group Mann-Whitney *U* comparisons of Montreal Cognitive Assessment change scores (per-protocol analysis).

Comparison	Test statistic (*Z*)	*P* value[a]	Effect size (*r*)	Interpretation
Physical vs control or low adherence	−0.527	.60	0.07	NS[b]
Cognitive vs control or low adherence	−1.291	.20	0.15	NS
Combination vs control or low adherence	−0.894	.37	0.12	NS

[a]*P*<.05 was considered statistically significant.

[b]NS: nonsignificant.

MoCA Subdomain Analysis (Wilcoxon Within Each Group)

Domain-specific analysis using Wilcoxon signed rank tests identified selective improvements across PP intervention groups (Table 8). The physical group demonstrated a significant improvement in the language domain (*P*=.01). The cognitive group showed significant gains in both language (*P*=.03) and orientation (*P*=.03), as well as a near-significant trend in visuospatial (*P*=.07). The combination group also showed a significant improvement in language (*P*=.02). No significant changes were observed in the control or low adherence group across all subdomains. These findings indicate that interventions incorporating cognitive elements, either alone or in combination with physical activity, particularly enhanced language and orientation abilities, which are important for executive and communicative functions among older adults.

Table . Wilcoxon signed rank results for Montreal Cognitive Assessment subdomains (per-protocol analysis).[a]

MoCA[b] subdomain	Physical (*P* value)	Cognitive (*P* value)	Combination (*P* value)	Control/low adherence (*P* value)	Interpretation summary
Visuospatial	.59	.07	.66	.22	Trend in cognitive group
Naming	.32	.32	.32	>.99	NS[c] across all groups
Attention	.78	.13	.66	.51	NS across all groups
Memory	.76	.81	>.99	.89	NS across all groups
Language	.01	.03	.02	.62	Improved in physical, cognitive, and combination groups
Abstraction	.66	.56	.32	.32	NS across all groups
Orientation	.41	.03	.26	.44	Improved in cognitive group

[a]*P*<.05 was considered statistically significant.

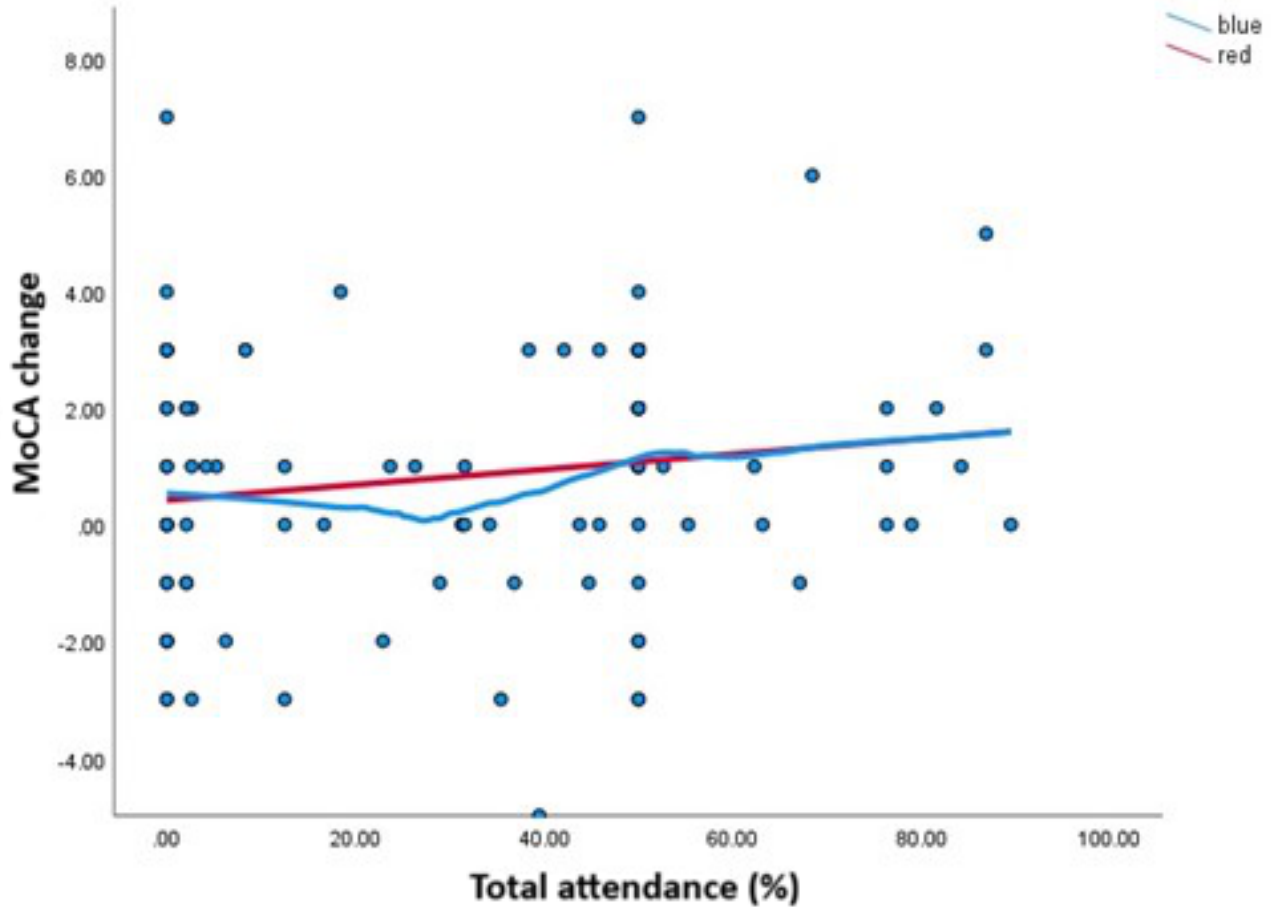
[b]MoCA: Montreal Cognitive Assessment.

[c]NS: nonsignificant.

MoCA Responder Analysis

When using a ≥2-point increase as the criterion for meaningful improvement, 37.5 (36/96) participants were classified as responders, while 62.5% (n=60) participants were nonresponders. Responders were most common in the cognitive and combination groups, supporting their greater within-group gains.

Attendance and Cognitive Change



Spearman rank correlation analyses revealed weak and nonsignificant relationships between attendance and MoCA improvement. Video game attendance showed a small positive correlation with MoCA change ($r=0.192$, *P*=.06), while total attendance was similarly weak ($r=0.159$, *P*=.12). Zumba attendance was not significantly associated with cognitive improvement.

Regression analysis further confirmed that attendance variables were not significant predictors of MoCA change (*P*=.18). ROC analysis indicated low discriminative accuracy of attendance measures in identifying cognitive responders, with area under the curve (AUC) values ranging from 0.45 to 0.59, suggesting poor predictive utility. Figure 3 illustrates the relationship between total attendance (%) and MoCA change. Linear (red) and locally weighted scatterplot smoothing (blue) trend lines

XSL•FO
RenderX

show a weak upward trajectory, consistent with the nonsignificant statistical findings.

Figure 3. Relationship between total attendance (%) and MoCA change. Scatter plot illustrating the association between total attendance (%) and change in MoCA scores among participants. Linear (red) and locally weighted scatterplot smoothing (blue) lines are shown. Both lines indicate a weak positive trend, consistent with the nonsignificant correlation and regression analyses. MoCA: Montreal Cognitive Assessment.

Discussion

This semirandomized trial found that physical (Zumba), cognitive (video game), and combined interventions were associated with within-group improvements in global cognitive function among older adults in Klang Valley, Malaysia. The combined intervention demonstrated the largest magnitude of improvement, although between-group differences were not statistically significant. Patterns of improvement suggested that adherence may play an important role in achieving meaningful cognitive benefits.

Cognitive impairment and age-related decline substantially affect daily functioning and independence in older adults. With rapid global aging and increasing dementia prevalence, effective preventive strategies are urgently needed [15]. Pharmacological approaches show limited success and are often accompanied by adverse effects [24-26], prompting growing interest in nonpharmacological interventions targeting cognitive frailty [27-31]. Despite this progress, the comparative effectiveness of different intervention modalities and their combinations remains uncertain [9]. Our study addresses this gap by examining physical, cognitive, and combined interventions on global and domain-specific MoCA performance, providing insights into strategies to preserve cognitive health in later life.

At baseline, there were no significant differences across groups in age (P=.96), sex (P=.23), MoCA scores before intervention (P=.77), or hypertension prevalence (P=.64), indicating a well-balanced distribution among participants. Recently, our research team examined the association between C-reactive protein (CRP) levels and various demographic factors. The analysis demonstrated that CRP concentrations were significantly correlated with gender, ethnicity, and BMI (P<.05), but not with age or economic status [18]. CRP is an inflammatory biomarker that plays a pivotal role in the pathophysiology of age-related conditions, including cognitive decline.

However, a significant between-group difference was observed in educational attainment (P<.001), which is a well-established determinant of cognitive reserve and MoCA performance. The cognitive group had the highest proportion of participants with a bachelor's degree, while the combination group included a relatively higher proportion with postgraduate education. This imbalance may have influenced both baseline cognitive performance and responsiveness to intervention, thereby complicating causal interpretation of between-group comparisons.

Although educational attainment differed across groups at baseline, the modest sample size and small subgroup numbers

XSL•FO
RenderX

limited the feasibility of conducting covariate-adjusted or stratified analyses to account for potential education effects. Consequently, the observed intervention effects may have been influenced by baseline differences in cognitive reserve associated with education. Nevertheless, prior research suggests that cognitively engaging and socially meaningful interventions can benefit older adults across a broad range of educational backgrounds [32]. These considerations highlight the need to interpret our findings cautiously and the importance of larger, well-powered trials to separate intervention effects from educational influences.

Overall, the mixed ANOVA results showed a significant improvement in cognitive performance, as demonstrated in MoCA score from preintervention to postintervention (P=.008), indicating that engagement in structured group activities can enhance cognitive outcomes in older adults, regardless of intervention type [33]. The time × group interaction, based on the mixed ANOVA, was not significant (P=.64), suggesting that the magnitude of cognitive improvement was similar across intervention types. These findings were further supported by Kruskal-Wallis and Mann-Whitney analyses in both ITT and PP approaches, which showed no significant differences in MoCA change scores in between-group comparisons or in pairwise comparisons of each intervention with the control group. Consistent with Barnes et al [34], who reported that 12 weeks of physical, cognitive, or combined activities in inactive older adults did not differ from the control groups, these findings suggest that overall engagement or the total amount of activity may be more influential than the specific type of intervention. One possible explanation is that nonspecific factors, such as social interaction, may contribute to the cognitive benefits observed [33].

The absence of significant between-group differences warrants further consideration. Several methodological and contextual factors may account for this pattern. First, the relatively small and unequal group sizes in the PP analysis, particularly the physical group (n=10), reduced statistical power to detect modest effects. Second, the improvements observed in the control group might be due to practice effects from taking the MoCA test multiple times or from nonspecific benefits such as social interaction, as previously noted by Lam et al [33], as well as incidental contact with the research team during assessments. Third, the sample's relatively high baseline MoCA scores (mean≈25) suggest a potential ceiling effect, limiting the magnitude of observable gains among cognitively healthy participants. Finally, interindividual variability in engagement and adherence may have contributed to heterogeneous treatment responses, attenuating between-group contrasts. These explanations are consistent with prior intervention studies showing that cognitive enrichment benefits can occur across multiple activity types, but group-level differences often emerge only with larger samples or higher training intensity [35-37].

Notably, the combination group showed numerically larger within-group improvements and more consistent effect sizes across analytic approaches, while the cognitive group also demonstrated significant gains in the PP analysis. Importantly, these significant improvements were observed only among participants who achieved at least moderate adherence (≥50% attendance), indicating that sufficient intervention exposure was necessary to elicit measurable gains in global cognition. However, between-group comparisons did not reveal statistically significant differences, indicating that cognitive improvements over time were broadly comparable across intervention conditions. Within this context, the relatively larger effect sizes observed in the combined intervention, reflected by large within-group effects in both the ITT (r=0.54) and PP (r=0.66) analyses, suggest a potential advantage of multimodal engagement when adherence is maintained. These patterns are consistent with previous reports indicating that combined physical and cognitive interventions may be associated with greater improvements in global cognition compared with single-modality approaches, as observed by Yu et al [35] and Han et al [36]. Mechanistically, dual-task or multitask training that integrates physical and cognitive elements has been proposed to support cognitive function through neurophysiological pathways, including reduced bilateral prefrontal cortical oxygenation [36], increased hippocampal volume [38], and improved white matter integrity [39].

The video game-based cognitive intervention demonstrated meaningful benefits in this study, particularly among participants who maintained at least moderate adherence in the PP analysis. This aligns with the meta-analysis by Lampit et al [14], which reported that computerized cognitive training produces small but significant improvements in cognitive performance among healthy older adults. Participants engaging more consistently with the cognitive intervention showed the largest gains, highlighting the importance of adherence in achieving measurable benefits. In contrast, the physical activity group showed minimal cognitive change across both analytic approaches, suggesting that a once-weekly Zumba session may not have provided a sufficient cumulative training dose to elicit substantial cognitive improvements.

Besides, Zhang et al [40] examined the effects of all FITT-VP (frequency, intensity, time [duration], type, volume, and progression) exercise variables on cognition across healthy populations, including older adults, and found that variations in FITT-VP influence cognitive benefits. Older adults showed the greatest improvements in global cognition, executive function, and memory. Yuan et al [31] similarly reported that exercise improved cognition in older adults with cognitive frailty, particularly when conducted 3 or more times per week, with each session lasting at least 45 minutes over 12 weeks or longer. Chia et al [17] also observed that participants with higher physical activity levels exhibited significantly greater median MoCA scores compared with less active participants. Collectively, these findings emphasize that exercise characteristics, including frequency, intensity, and session duration (time), are crucial determinants of cognitive outcomes.

The present findings are consistent with recommendations from the American College of Sports Medicine and prior meta-analyses. Northey et al [41] reported that moderate-intensity exercise lasting at least 45 minutes per session on most days of the week enhances global cognition in adults aged 50 years and older. Xue et al [42] similarly found that moderate-duration, moderate-intensity exercise is associated with significant cognitive improvements among older adults.

XSL•FO
RenderX

Although these studies do not explicitly recommend the FITT-VP framework, their results indirectly support its core principles, particularly frequency, intensity, and time, as key determinants of cognitive benefit.

In this study, Zumba sessions were delivered once weekly for 60 minutes over approximately 19 weeks. While session intensity was appropriate, the low frequency likely limited cumulative training dose, providing a plausible explanation for the minimal cognitive gains observed. Applying FITT-VP principles as an interpretive framework highlights the importance of optimizing exercise frequency, duration, and intensity in future interventions to ensure sufficient training stimulus for measurable cognitive improvements among older adults. While each intervention component was matched in session duration, the combined arm received a higher total weekly exposure, and this difference in intervention "dose" was considered when interpreting between-group comparisons.

The study was further extended with subdomain analyses under both analytic approaches (ITT and PP) to explore domain-specific responsiveness to the different interventions. The results showed that the language domain, which included assessments of verbal, categorical, and phonological fluency [43], demonstrated the most consistent improvement across all intervention groups. This suggests that verbal fluency and communication-related cognitive processes are particularly sensitive to structured and socially interactive activities. These findings are also supported by previous studies, although the results varied depending on the intervention type. Nocera et al [44] reported that aerobic exercise improved verbal fluency, whereas cognitive training was associated with decreased or nonsignificant improvement in this domain. In contrast, Calatayud et al [45] demonstrated that a comprehensive cognitive stimulation program significantly enhanced language proficiency, verbal fluency, and overall cognitive function. These contrasting findings indicate that the type and structure of the intervention may differentially influence specific cognitive domains.

Significant gains in the visuospatial domain were observed in the combination group in the ITT analysis, while improvements in orientation emerged in the cognitive stimulation group and reached significance in the PP analysis. These patterns suggest that distinct cognitive mechanisms may underlie the effects of different stimulation modalities. Interventions that combine physical and cognitive elements may enhance visuospatial and integrative processing, whereas purely cognitive activities may strengthen orientation. Collectively, these subdomain-level findings highlight the importance of examining domain-specific outcomes beyond total MoCA scores, as they may reveal early indicators of intervention efficacy [15].

Exploratory analyses examining adherence showed that attendance rates were not significantly correlated with MoCA improvement. While weak positive associations were observed for video game and total attendance, regression and ROC analyses showed limited predictive value for cognitive improvement. This suggests that mere attendance frequency may not fully capture the quality or engagement level of participation, underscoring the complexity of dose-response relationships in behavioral interventions. Nevertheless, adherence remains clinically relevant, as participants with consistent engagement in cognitive or combined activities demonstrated the most robust improvements in the PP analyses.

From a clinical perspective, these findings highlight the feasibility of combined physical and cognitive interventions as a practical approach for promoting cognitive engagement among older adults. While between-group differences were not statistically significant, the consistent within-group improvements and favorable subdomain patterns observed in participants with higher adherence suggest that sustained participation in structured multimodal activities may be beneficial in real-world community settings.

In relation to previous literature, the present findings are consistent with meta-analyses reporting small-to-moderate improvements in global cognition following cognitive and combined interventions [15,46]. This study adds novel insights by directly comparing physical activity, cognitive stimulation, and combined training within a single cohort, employing both ITT and PP analytic frameworks and mapping MoCA subdomains to identify domain-specific responsiveness. Such findings contribute to growing evidence that multimodal engagement may support cognitive health in aging populations, although definitive conclusions regarding superiority over single-domain training require larger, adequately powered trials.

Several limitations should be acknowledged. The semirandomized allocation and lack of blinding may have introduced expectancy effects, although baseline characteristics were comparable across groups and standardized outcome assessments were used to mitigate potential bias. Additionally, the sample size was modest and uneven across groups, limiting statistical power and precision. The intervention frequency (once weekly) and duration may have been insufficient to elicit large cognitive changes. Cognitive outcomes were based solely on the MoCA, without complementary neuropsychological or neuroimaging measures. Moreover, the study lacked long-term follow-up, preventing evaluation of the persistence of cognitive gains. Furthermore, as participants were community-dwelling older adults from a single urban region, generalizability to rural or clinical populations is limited.

Besides, adherence thresholds for the PP analysis were pragmatically defined at ≥50% attendance. Sensitivity analyses using higher cutoffs (70% - 80%) yielded directionally similar results, but small subgroup sizes reduced statistical stability, highlighting the trade-off between stricter adherence definitions and analytic feasibility in nonpharmacological interventions. Pooling participants with no intervention exposure and those with partial exposure below the ≥50% adherence threshold increased heterogeneity and may have attenuated detectable between-group differences.

Finally, formal 95% CIs for nonparametric between-group effect sizes were not calculated due to methodological constraints with small, skewed samples. Consequently, effect sizes (r and η^2) were used to indicate magnitude and direction rather than statistical precision, and between-group findings should be interpreted cautiously.

XSL•FO
RenderX

In summary, both cognitive and combined interventions produced meaningful improvements in cognitive performance among older adults, with the strongest effects observed when adherence was maintained. Although between-group differences were not statistically significant, the consistent within-group trends and domain-specific patterns suggest practical cognitive benefits of engaging in regular, structured multimodal activities. Future research with larger samples, longer intervention durations, and multidomain cognitive assessments is warranted to confirm these findings and further clarify the mechanisms underlying differential cognitive responsiveness.

This study demonstrates that participation in video game–based cognitive stimulation, physical activity, and combined interventions was associated with within-group improvements in global cognitive performance among community-dwelling older adults. PP analyses indicated that participants who attended at least 50% of the cognitive stimulation sessions showed moderate improvements, while those who adhered to at least 50% of both the physical and cognitive components in the combined intervention demonstrated numerically larger and more consistent gains. Domain-specific analyses suggested that language, visuospatial, and orientation abilities may respond differently to intervention type. Although between-group differences were not statistically significant, consistent within-group trends support the practical value of structured engagement in cognitive and combined activities. Future studies with longer durations, higher frequency or intensity of physical activity, larger sample sizes, and multidomain cognitive assessments are needed to clarify the mechanisms underlying intervention-specific cognitive responsiveness.

Acknowledgments

The authors acknowledge the Ministry of Higher Education Malaysia for funding this work. They are grateful to all postdoctoral research fellows, graduate research assistants, research assistants, and interns for their invaluable contributions to the project. They also extend their sincere thanks to all participants for their time, commitment, and active involvement in the intervention sessions. ChatGPT (OpenAI) was used to support language editing during the preparation of this manuscript. The authors reviewed and edited all content and take full responsibility for the accuracy, originality, and integrity of the manuscript.

Funding

This study was supported by a research grant from the Ministry of Higher Education Malaysia (LRGS/1/2019/SYUC/02/1/1) and Sunway University.

Abstract

Background: The older adult population is increasing rapidly and experiences a multitude of chronic conditions affecting quality of life. Physical activity and reduced sedentary behavior reduce adverse health conditions and help preserve functional independence and cognitive abilities, but the older adult age group has much lower levels of physical activity than recommended compared with other population demographics.

Objective: The study aimed to understand older adults' motivations toward health and physical activity and the role of technology in achieving their health and physical activity goals and to explore the attitudes toward the use of generative AI in health apps.

Methods: This study was qualitative and based on hour-long interviews with 20 older adults living in the United States. To elicit specific design preferences, participants were presented with visual probes of AI-generated avatars. The interviews were analyzed using thematic analysis, and the coding process drew on reflexive and grounded theory techniques.

Results: Older adults primarily wished to maintain functional independence, both physical and cognitive, prioritizing baseline maintenance rather than continuous optimization. They reported satisfaction with levels of physical activity, adjusting them to chronic conditions and injuries. They were active through everyday functions of living as well as structured exercise programs with many participants using wearable devices and smartphones to help monitor their activity. They reported being motivated by social accountability and gamification, although some found the latter condescending or anxiety-inducing. Accessibility issues were mentioned frequently, including problems with touchscreens, limited viewing, difficulty navigating interfaces with clutter, complex multitouch processes for undertaking actions, and steep learning curves. Computers were preferred for certain tasks over mobile phones due to easier viewability, keyboard access, and greater security features. Personalization was highly desired in health apps. There was a willingness to use more health technology, including generative AI, and they were willing to consider AI in both motivational and informational roles in apps as long as it was personalized. AI embodiment preferences varied widely but with an emphasis on relatability. However, there was marked skepticism toward data privacy, concerns about the loss of independence and self-efficacy, and doubts about AI's accuracy.

Conclusions: Older adults are primarily motivated by sustaining functional independence, although accessibility barriers in current health apps remain. Participants were open to AI for physical activity support, but expectations varied. They viewed AI as a passive "tool," a directive "coach," or a relational "companion." Considerable variation in preferences for gamification and visual design suggested that future apps require greater modularity. As skepticism over data privacy and AI accuracy remains high, greater transparency and explainability might be needed to engender trust.

Introduction

Older Adults and Physical Activity

The demographic composition of the global population is trending toward a higher proportion of older adults, a shift that presents significant public health challenges across the world [1]. According to the 2020 Census, the US population aged >65 years stood at 55.8 million, or 16.8% of the general population [2]. This demographic grew nearly 5 times faster than the total population over the 100 years from 1920 to 2020 [2]. Older adult populations commonly experience a multitude of chronic conditions that accrue with age and also worsen due to decreasing physical activity (PA) with age [3]. PA and reduced sedentary behavior have proven benefits for older adults, including the prevention of chronic disease, maintenance of functional independence, and preservation of cognitive health [4]. Despite these known benefits, a large portion of the older adult population in the United States does not meet recommended PA guidelines [5], making the development of effective, scalable interventions for sustained PA in older adults increasingly important.

Technological Changes in Digital Health

Recent rapid developments in technologies have resulted in increasing applications to the health domain. Digital health is an umbrella term for all uses of digital technologies to improve health and well-being, and it includes computer-based, remote, mobile, and ubiquitous solutions [6]. On the whole, digital interventions have been found to be effective in PA interventions for older adults across many studies in the past few years [7], primarily by facilitating continuous self-monitoring and reducing logistical barriers to exercise. Such technologies, including smartphone apps, wearables, and AI-powered conversational agents, have shown the potential to be scalable and cost-effective solutions [8]. Real-life applications have also been employing gamification: the use of game design elements in nongame contexts [9]. Gamification has been found to be beneficial in the health domain [10] and shown to help older adults in having higher levels of motivation, enjoyment, and engagement while performing PA [11].

Research Gap Motivating This Study

However, a persistent gap has been observed between the high potential of these tools and their low adoption and sustained engagement by older adults [12]. This suggests a fundamental disconnect between the technological solutions offered and the actual needs, motivations, and practices of this user group. A recent systematic review found that limitations in capability, motivation, and social support were principal in limiting the uptake of mobile health (mHealth) solutions among older adults and suggested blended approaches of face-to-face interactions with technological interventions as a way to improve adoption [13]. Other research has identified 10 factors as determinants of older adults' adoption of mHealth: value, usability, affordability, accessibility, technical support, social support, emotion, independence, experience, and confidence [14]. Tailoring is also associated with much greater adherence rates [15]. Current older adult fitness technologies may also be lacking alignment with the needs and preferences of older adults [16].

To better understand their needs and preferences, we conducted interviews with 20 older adults to answer the following research questions:

1. What are older adults' foundational health goals and primary motivations regarding PA?
2. What are older adults' current practices regarding existing health technologies (eg, smartwatches and fitness apps) and what specific accessibility barriers do they experience?
3. How do older adults perceive the hypothetical use of AI-powered conversational agents for PA, and what specific roles and trust-related concerns do they envision?

Background

The mHealth Technology Landscape

The mHealth landscape for older adults extends beyond the relative ubiquity of smartphones and wearables to include tablets and emerging unobtrusive monitoring technologies. While personal mobile devices are effective for short-term PA promotion, their long-term utility is often limited by high abandonment rates once the novelty fades. There is also a persistent digital divide in active usage. Although hardware ownership is rising, particularly among highly educated older adults, sustained engagement remains a challenge across the demographic [17,18]. To mitigate the visual and dexterity deficits associated with these smaller screens, research demonstrates that tablet-based interventions can offer distinct usability advantages, allowing older adults to engage more effectively with complex health dashboards due to the larger screen real estate [19]. Furthermore, the landscape is shifting toward ambient computing and voice-first interfaces, which offer a lower barrier to entry for users with limited mobility or technical literacy [20].

Accessibility and the Limits of Usability

Historically, low adoption of mHealth technologies among older adults was attributed to physical and cognitive barriers. Systematic reviews confirm that age-related declines—specifically in manual dexterity, visual acuity, and cognitive processing speed—create significant hurdles for standard smartphone interfaces [12]. Wildenbos et al [21] demonstrated that basic interface deficits, such as small touch targets, complex navigation hierarchies, and insufficient contrast, can render an app functionally unusable regardless of the app's intent. However, addressing usability alone does not guarantee engagement. Foundational information systems theory, specifically the senior technology acceptance model (STAM), confirms that for older adults, attitude and utility ultimately mediate the impact of physical limitations [22].

A Look at Engagement: Foundational Techniques and Gamification Strategies

To drive engagement beyond simple utility, gamification is frequently used to foster motivation. While substantial evidence supports its general efficacy in improving health outcomes [23], the evidence specifically for older adults is less robust [10]. Considering self-determination theory (SDT), mechanics

XSL•FO
RenderX

designed to drive extrinsic motivation (eg, points, badges, and leaderboards) may fail to sustain engagement if they distract from the direct insight provided by self-monitoring or fail to support the user's intrinsic health goals. Tabak et al [24] illustrated this risk, noting that specific game elements can sometimes weaken the correlation between the app and the actual health goal if they distract from the direct insight provided by self-monitoring. Consequently, it is argued that gamification for this demographic must be applied with "adaptive engagement," allowing users to customize motivational affordances to their specific needs [11].

Social Connectedness Paradox and Privacy Barriers

Social support is widely recognized as a determinant of PA, but digitizing it presents unique risks; purely cognitive behavior change techniques are often less suitable for older adults compared to meaningful social support [25]. This uncertainty is often driven by a virtual paradox of connectedness: while older adults desire connection, they frequently reject the specific digital mechanisms used to facilitate it. This tension can be understood through socioemotional selectivity theory (SST), which posits that as time horizons shrink, older adults prioritize emotionally meaningful relationships with close friends and family over knowledge building with peripheral acquaintances [26]. Consequently, mHealth features that broadcast data to a wide, impersonal network conflict with this preference for selective intimacy. Orji [27] found that while competition can foster commitment, it introduces significant risks for this demographic, including heightened anxiety regarding self-esteem. Privacy barriers further compound this issue; older adults are significantly more likely to raise concerns about data confidentiality [28]. As a result, forced digital interaction can alienate users, who often prefer offline socialization, such as discussing results privately with family [24], over built-in cooperative elements that appeal only to specific, highly social user types [29].

Social Presence of Conversational AI

Conversational agents (CAs) are evolving rapidly, and those with unconstrained natural language input yield high user satisfaction and improved health outcomes, particularly in chronic disease management; they can foster a relationship similar to human coaching, where the natural language modality itself builds rapport [30]. This is supported by findings that the act of vocalizing health goals to an agent encourages psychological commitment [31,32]. Humans subconsciously apply social rules to computer interfaces, and this tendency toward anthropomorphism is particularly pronounced in older adults, who often use human social scripts to navigate digital interactions [33,34]. Embodiment appears to be helpful in gaining trust and acceptance among older adults [35,36]. An embodied virtual representation, commonly called an "*avatar*," can be a tool for persons for mediating communication and to derive meaning from interactions with the environment [37]. This perception as social entities increases engagement but introduces design risks [38]. Hyperrealistic avatars can elicit "uncanny valley" discomfort, while cartoonish representations may be perceived as patronizing [39]. Concepts of homophily suggest a preference for peer-like avatars to facilitate trust [40], and recent research affirms that properly designed peer-like CAs are effective partners in increasing PA and dietary behaviors [41].

The Research Gap

The existing literature is extensive but fragmented, often examining domains such as usability, gamification, and trust in isolation. Furthermore, the prevalence of interventionist studies creates a bias toward evaluation, where user insights are constrained by the specific features of a prototype rather than revealing the user's broader context. Consequently, there is a lack of comprehensive research that synthesizes the relationship between an older adult's foundational health goals, their existing technology habits, and their trust requirements for future AI interactions. To bridge this gap between current behaviors and future expectations, this study adopts a multitheoretical lens. By integrating the STAM for usability, SDT for motivational goals, and SST for social and privacy preferences, we conducted interviews with older adults about their attitudes toward PA, current PA practices and barriers, and their perceptions of an AI-based tool for supporting PA.

Methods

Participants and Recruitment

To meet study inclusion criteria, participants had to be 65 years of age or older, reside in the United States, and speak conversational English. Recruitment was conducted through university email listservs, flyers, and the newsletter of a prominent lifelong learning institute for older adults. Interested participants completed a demographic questionnaire to determine eligibility, and the research team screened them based on responses. After every fresh outreach effort (listserv, flyer, or newsletter), interviews were scheduled with all eligible participants. Thereafter, a fresh outreach effort was made until the target sample size (n=20) was reached. A total of 30 unique respondents filled out the screening survey, but only 28 individuals were eligible, of whom 20 finally consented to being interviewed.

Data Collection and Procedure

Interviews were conducted between May 2024 and January 2025 via videoconferencing software (Zoom; Zoom Video Communications) by the primary researcher. The sessions followed a semistructured format lasting approximately 1 hour. All interview data regarding PA and technology usage relied on participant self-report. The interview protocol was developed following guidelines for qualitative research questions [42] and covered health technology usage, challenges, and goals (Multimedia Appendix 1).

To elicit specific design preferences regarding AI embodiment, participants were presented with a series of visual probes. These consisted of AI-generated images (created using DALL-E models [OpenAI]; see Multimedia Appendix 2) depicting potential "*health coach*" avatars in fitness-oriented environments. The stimuli included the following:

- Realistic human avatars: young male, young female, older male, and older female.

XSL•FO
RenderX

- Robot avatars: a smiling bipedal robot and a plain bipedal robot.
- Animal avatars: a realistic dog, a cartoonish dog, a realistic cat, and a cartoonish cat.

These were intended to give participants a variety of choices in avatars. The clothing (sportswear) and background (sports field) of the avatars were selected so as to be associated with PA. There were no other selection criteria for the selected avatars, and the first image generated by the prompt was accepted as long as it followed the prompt accurately (eg, a prompt asking for a cartoonish dog got a cartoonish dog as a response and not a real dog image). Prompts used are provided in Multimedia Appendix 2.

Interviews were recorded on Zoom and transcribed using automated transcription services (Zoom and Whisper AI [OpenAI]), then checked for accuracy by the primary researcher.

Data Analysis

Data analysis used a hybrid inductive approach. The overall framework was reflexive thematic analysis as described by Braun and Clarke [43], elected for its flexibility in identifying overarching patterns across a heterogeneous dataset. Within this constructivist framework, we adopted specific coding procedures from the grounded theory tradition [44]—namely open line-by-line coding—strictly as practical tools for systematically building initial codes from the data upward. Acknowledging the epistemological debates between these methods, this pragmatic combination [45] was chosen specifically because the structured coding of grounded theory facilitated deep data familiarization, which then transitioned fully into the interpretive, theme-building processes of reflexive thematic analysis [43,46], without committing to a positivist theory-building paradigm.

The analysis proceeded in 3 stages. First, transcripts were subjected to initial coding to identify initial concepts. Every recorded video was viewed with the transcript in hand during this stage. Second, iterative grouping was applied to organize these codes into broader categories and explore relationships between them. Finally, these categories were synthesized into the final themes reported. To ensure rigor, initial coding was conducted independently by 2 researchers across the entire dataset (n=20). The researchers then brought their independent coding together, and contrasting perspectives were explored through collaborative reflexive dialogue in regular meetings to develop richer, multifaceted conceptual themes. Throughout this process, researchers maintained detailed reflexive notes. The process was conducted and tracked by hand, with pen and paper, whiteboard, sticky notes, and Microsoft Excel to ensure dependability and confirmability.

Thematic sufficiency was assessed informally by monitoring whether new interviews introduced significantly novel concepts. By the final 5 interviews (P16-P20), no new codes were generated during initial coding, suggesting thematic sufficiency within this sample [47]. However, we acknowledge that the demographic homogeneity of our participants may have contributed to earlier convergence and that saturation might not hold if sampling were extended to more diverse populations.

To categorize how participants imagined AI supporting their health and PA, our thematic synthesis organically generated an inductive typology based on participants' primary orientations toward the agent's role. Data interpretation was actively shaped by the coding team's diverse positionalities. The primary researcher had an eclectic multidisciplinary background across computer science engineering, finance, and other disciplines, coupled with personal experience as a caregiver for an older adult. Furthermore, an extensive experience of interviewing individuals in both industry and academic settings, personal engagement with structured exercise routines, nondigital heuristics, fitness apps, and various AI models provided a nuanced understanding of the tools being discussed. This combination had considerable impact on the semistructured interviews by shaping the conversation. The primary researcher's understanding of older adults' heuristics helped elicit deeper insights into technology usage and avoided viewing any struggles as skill deficiencies. Conversely, the secondary coder, a computer science major, brought a younger, digitally native perspective, while a practical background as a lifeguard provided a grounded lens on physical safety and fitness. During the "Four Eyes" evaluation, this contrast was highly productive. It established the credibility of our interpretations by preventing technical biases or overly sympathetic caregiving perspectives from overshadowing the older adults' verbal accounts. Finally, our detailed demographic reporting allows readers to judge the transferability of these insights.

Building on this reflexive approach, our thematic analysis was intentionally theoretically sensitized by the multitheoretical lens introduced earlier. To maintain the inductive integrity of reflexive thematic analysis, initial codes were generated directly from the participants' reported practice and perceptions. However, STAM, SDT, and SST provided the analytical vocabulary necessary to elevate these descriptive codes into our conceptual themes, ultimately shaping the resulting tool, coach, and companion typology.

Ethical Considerations

This study protocol was approved by the University of Illinois Urbana-Champaign's Institutional Review Board (project IRB24-0536). Informed consent was obtained from all participants prior to data collection. Qualitative data and interview transcripts were deidentified and assigned participant codes (eg, P1, P2) to ensure confidentiality. Participants received Amazon gift cards worth US $20 each as compensation for their time.

Results

Demographic Characteristics

Twenty participants (men: n=7, 35%; women: n=13, 65%) were interviewed regarding their experiences with health technology. The sample was highly educated, with all participants holding at least an undergraduate degree. The sample was relatively homogeneous in terms of ethnicity. All collected participant demographic data are presented in Table 1 and are self-reported.

Attitudes and Motivations Related to PA

Attitudes Toward PA

Self-Reported Activity and Satisfaction

A majority of participants (12/20, 60%) reported maintaining active lifestyles, although the structure and intensity of this self-reported activity varied widely. (Subjective satisfaction with one's activity level may not necessarily correspond with meeting established PA guidelines.) Their PA regimens included structured exercises (eg, circuit training, resistance training, yoga, swimming, and sports) as well as lifestyle activities, such as gardening, walking the dog, and household maintenance.

An example of a highly structured, multifaceted routine was provided by P1:

> *Right now, I work out with a trainer three mornings a week. I walk every day. I'm always on the go. So, I usually log about 10,000 steps a day.*

Others integrated activity into their necessary daily tasks; P6 said:

> *I'm pretty active in the morning. I walk my dog twice... I do some gardening.*

Participants also reported satisfaction with their current level of PA. Their goal was maintenance, seeking to sustain their current baseline activity, rather than seeking continuous improvement. P8's comment reflected a common sentiment:

> *I'm not training for a marathon, but I get my steps in, I do my gardening... I feel good. At my age, I think I'm doing just fine.*

However, not everyone liked PA. P10 was happy with her low activity levels, listing multiple reasons for her dislike, including profound boredom ("It's so repetitive. I'd rather read a book") and sensory discomfort ("I just hate sweating").

Pragmatic Adaptation to Physical Barriers

This satisfaction was maintained through active negotiation with the physical realities of chronic health conditions and past injuries. These ranged from bone and joint issues to heart issues and past surgery history. P2 described the impact of chronic issues affecting the type of PA:

> *I've had high blood pressure since I was in my early 40 s...I wonder if I should be a little more gentle... I don't want to have surgery on my neck.*

It also manifested in a continual process of adaptation involving finding new activities to replace those no longer safe to perform. P5 swapped hiking with water aerobics:

XSL•FO
RenderX

> *I'd love to go on the long hikes I used to, but with the arthritis in my knee... I just can't. So now, I do my water aerobics. You do what you can.*

Motivations Aiding Health and PA

Functional Independence

Participants by and large were motivated with the aim of living a quality long life and preventing functional immobility. They framed having a certain level of functional fitness as a prerequisite to valued activities, such as being able to engage with family, avoiding emergency health circumstances, preventing cognitive decline, and also looking or feeling good. P13 framed it as a "straightforward" choice:

> *Well, at my age you have to decide, do I want to live or do I want to die?*

PA was similarly linked to cognitive preservation; participants viewed exercise as essential for maintaining mental clarity alongside physical capabilities (especially P13 and P18). Rather than seeking continuous improvement, their long-term objectives focused on sustaining baseline health—such as retaining energy and speed (eg, P6) and avoiding hospitalization (eg, P5).

Familial Motivation

Participants expressed a strong desire to maintain their health to see their descendants grow (eg, P8). P20 vividly described how losing weight would allow her to safely engage with her family:

> *I'll be able to play with my grandson instead of getting down and feeling like I can't get back up because it's hard to get up when you have all this extra weight.*

Sense of Community

Most participants (12/20, 60%) cited social factors and motivations when discussing their PA. Participants liked working with other people such as their spouse, children, friends, or an exercise class.

The sense of community was crucial for some and helped with exercise adherence, providing motivation and even a sense of security. Participants noted that group settings, such as yoga or classes, instilled the discipline required to maintain routines (eg, P11), while also offering peer-monitoring that made them feel safe (eg, P20). P4 was very expressive in describing the value of community:

> *The encouragement usually comes from enjoying the game with other people...[I] make sure I have enough good social activities for my health. I think that's important for the mental side of health. Coming into contact with social groups and through activities that I do... and also with my children to socially interact with them.*

Competition

A healthy sense of competition helped some participants, but this was typically with close family members or even against oneself. P2 mentioned an example of competition between mother and daughter based on achieving the activity levels tracked by Apple Health, which are shown as rings.

> *I found that I was more motivated when I was doing it with my daughter. She was sharing her rings, and I was sharing mine. I liked that competition.* [P2]

While intimate competition within the family proved motivating, broad group-based competition was often rejected. Participants favored collaborative or self-referential tracking (eg, P9), actively disliking generalized leaderboards. As P11 noted regarding university-wide step challenges, comparing oneself against strangers "doesn't motivate me, but against myself, yeah."

One participant was motivated by optimizing physical health, focusing on proactively improving performance in competitive bodybuilding:

> *We are not just messing around. We work out 6 days a week... It's a lot when you're competing.* [P14]

Accountability and Routine

Having someone else to discuss one's health objectives and progress with was listed as a key motivation by a number of participants, and this was often routine based. This accountability took various forms, ranging from formal weekly weigh-ins with nutritionists (eg, P3) to informal peer pressure from a spouse or "buddy" (eg, P14). Some participants even expressed a desire for "nagging reminders."

For some, this accountability was maintained through rigid schedules rather than direct supervision, such as committing specific days of the week to racquetball or fencing (eg, P4). Others relied on self-styled, task-based routines as a proxy for tracking overall activity, measuring their physical output. For example, P7 measured it by daily gardening milestones:

> *How long is the grass? How many weeds are in the garden? How many tomatoes and cucumbers have I picked today?*

Professional accountability from personal trainers or community instructors was highly valued for providing tailored motivation (eg, P17). More importantly, participants prized instructors who understood age-specific physiological issues and could proactively offer modifications for injuries or joint problems, ensuring the exercise remained both safe and effective (eg, P3).

Health Technology Apps: Attitudes and Barriers

Attitudes

Willingness to Adopt

Almost half (9/20, 45%) of the participants were current users of health apps, while others had used them in the past. Of nonusers, several people felt optimistic about using them. For some, potentially life-saving features such as fall detection and continuous heart rate monitoring were the key reason for use, particularly for those living alone (eg, P1). Some participants were more likely to use apps integrated with their current ecosystem, such as Apple's, essentially for the ease of compatibility with existing hardware.

XSL•FO
RenderX

Health apps were widely considered convenient for routine tracking. P6 preferred digital tools that automatically organized their data over manual methods such as writing in notebooks, noting that digital apps provided greater accountability (eg, P9). This convenience was further amplified by age-specific customization and seamless integration with existing services, such as health insurance platforms (eg, P3).

Unwillingness: Threat to Self-Efficacy and Feelings of Condescension

Six (30%) participants mentioned not wanting to track their health at all with reasons ranging from lack of need to it being effortful. A perceived loss of self-efficacy was a major barrier and participants actively resisted technology that felt overly prescriptive. P16 was emphatic:

> *I want to feel that I'm in control of the phone, not the phone in control of me.*

It also felt condescending for P19:

> *I don't need a pat on the back. I know I'm doing it. I don't need to write it down.*

App features were underused partly due to the feeling of loss of independence. P1 expressed this sentiment best:

> *I don't use a lot of the capacities... I don't like that it tells me to breathe. I know to breathe... I was raised to be independent, so I don't need some piece of software telling me that it's time to do something unless I've set an alarm.*

Barriers

Overview

All (20/20, 100%) our participants used technology regularly in their lives with many also possessing smartwatches (18/20, 90%) and voice-based personal assistants (8/20, 40%). Only 2 (10%) participants did not use smartphones, although they used computers. Nevertheless, many barriers and issues with technology were identified. These could be divided into accessibility issues and user preference mismatches. Although older adults aged ≥75 years reported more accessibility concerns, many aged 65 to 74 years also had similar concerns.

Accessibility: Physical Constraints

Accessibility issues proved to be a major barrier to usage. These ranged from physical constraints, such as arthritis affecting touchscreen use, to cognitive difficulties in learning new workflows. Small mobile interfaces actively hindered interaction, with participants struggling against illegible font sizes (eg, P18) and the physical pain of using tiny keyboards (eg, P9). Consequently, a significant number of participants explicitly preferred computers or tablets, seeking the physical affordances of larger screens and tactile keyboards (eg, P15). As P7 stated:

> *I got myself a keyboard with larger keys...My fingers miss a lot, especially if I'm doing texting... [Computer's more comfortable] because the print's bigger... I can see more on the screen.*

While some participants preferred voice interactions to bypass typing difficulties (eg, P4), they often encountered recognition errors, noting that systems struggled to understand their enunciation and frequently transcribed commands incorrectly (eg, P2).

Furthermore, modern devices were often viewed as unforgiving. Heightened touchscreen sensitivity and shifting interaction modes led to hesitation in adopting newer hardware. P13 expressed his exasperation:

> *Sometimes it's annoying that the more features they put on the iPhone or any of these, the harder these buttons are to navigate. I'm always accidentally going somewhere where I don't want to go... this is an iPhone 12. The reason I don't have the 15 is my daughter has it and ... just do that and screens disappear and new stuff comes on. It's too sensitive.* [P13]

Accessibility: Cognitive Overload

Participants frequently indicated a strong preference for visual simplicity, frequently reporting feeling overwhelmed with complex menus (eg, P11) or excessive data visualizations such as multicolored line graphs (eg, P9).

Unfamiliar iconography compounded this frustration, sometimes leading to outright abandonment, as P1 recalled:

> *When I go to an app that's just filled with symbols and I have no idea what they are, I just turn it off and go to something else.*

Extraneous options and constant notifications further contributed to information overload, occasionally driving users to the brink of returning their devices (eg, P13). Participants viewed these interruptions as highly disruptive to their workflow:

> *All these other things are coming up. Do you want to do this? Do you want to upgrade? Very distracting and very annoying... Let me just finish what I'm doing. Don't overload me with too much. People that are older are not used to that level of overload.* [P16]

Accessibility: Learning Difficulty and Complex Processes

Advancing age made learning more difficult for participants, leading to them expressing a marked preference for short and smooth learning curves (eg, P12). Multistep procedures were flagged as a specific barrier to adoption. P3 described this frustration:

> *The only time I think it really gets difficult as if I can't figure out what steps to take to get to what I want to do; if it's too many steps... do this now do that now... there are 10 or 12 steps... The easier it is to access the information I want, the more likely I am to use the technology.* [P3]

Convoluted navigation flows were censured, with some participants finding deeply nested tasks across multiple screens virtually impossible to complete. As P4 stated passionately:

XSL•FO
RenderX

> *Navigation to me is one of the cruelest things if it's not done correctly, especially for people that are a little older.*

Mismatch With User Needs

Apps were also criticized for not putting user needs first but instead prioritizing developer needs or lazily adapting study results:

> *I just think it's so distilled...not even the essence of what you need. It's more like some coder, some developer, who might look at a study or something put down what they think should be in the app, not what you need from the app.* [P5]

Participants strongly desired automated, minimal-effort setup processes for new wearables (eg, P4). When initial configuration proved too complex, users often had to surrender their independence and rely on younger family members for assistance before they could comfortably use the device (eg, P20).

Health App Preferences

Gamification Preferences

The majority (14/20, 70%) of participants showed an affinity for gamification, considering it useful for motivation. Many features of gamification came up, ranging from levels and points to leaderboards and competitive streaks.

Motivated by Gamification

Tangible rewards, such as points tied to health insurance premiums (eg, P2) or daily step targets (eg, P17), provided clear milestones that drove users to finish their daily routines. Participants generally responded well to this positive, automated feedback (eg, P9).

The motivation provided by awards and the ability to share with family added a social dimension. Reference points for distance helped too. This was best expressed by P20:

> *They would send those little award things. You've gone this many steps, walked this many miles...it's funny. In the beginning, I would send it to my kids. I said, "Look what I did." I was all excited, Oh, my gosh! I mean, it was kind of neat because it made you feel like you've gone this far already, and you don't think of it when you're doing it... It was nice. It's silly things, but it was just kind of neat to see.* [P20]

While some users thrived on the interpersonal competition of leaderboards (eg, P16) or the discipline of maintaining multiday streaks (eg, P17), others found deep motivation in personal, visual targets. The visual appeal of closing daily activity rings drove direct behavioral changes, as P19 confessed:

> *I like the [Apple Watch] rings... I want to close my rings. So, I will walk around the kitchen island... to get my steps in to close my rings... It's a bit silly, but it works.*

Unmotivated by Gamification

Conversely, 7 (35%) participants explicitly stated that they were unmotivated by gamification, dismissing such features as childish, distracting, or irrelevant to their intrinsic health goals. Its purported usefulness still failed to make them comfortable with it (eg, P12) and some even called it inherently unsuitable for their demographic, as expressed by P6:

> *I don't think people my age think in those terms [levels, badges, challenges].*

Excessive focus on gamification was also regarded as a source of anxiety. A quote by P8 illustrates this:

> *One of the one of my goals for the last 10 years is not to be too judgmental. I have friends who are really disappointed when they don't get their 10,000 steps... where it becomes worrisome to them... the worrying is worse than not getting the 10,000 steps in.*

Privacy Preferences

A quarter (5/20, 25%) of participants expressed very strong concerns about use of their data and privacy, citing fears of hacking (eg, P4), the commercial exploitation of even ostensibly anonymized personal data (eg, P5), and the financial extortion targeting their age demographic (eg, P13). This often manifested as a visceral and pervasive feeling of unease because the technology was literally "listening in." P13 was cogent:

> *[Siri] gives me the feeling that I'm being watched... I don't know who's all in on that conversation. The same with Amazon.*

Informational Preferences

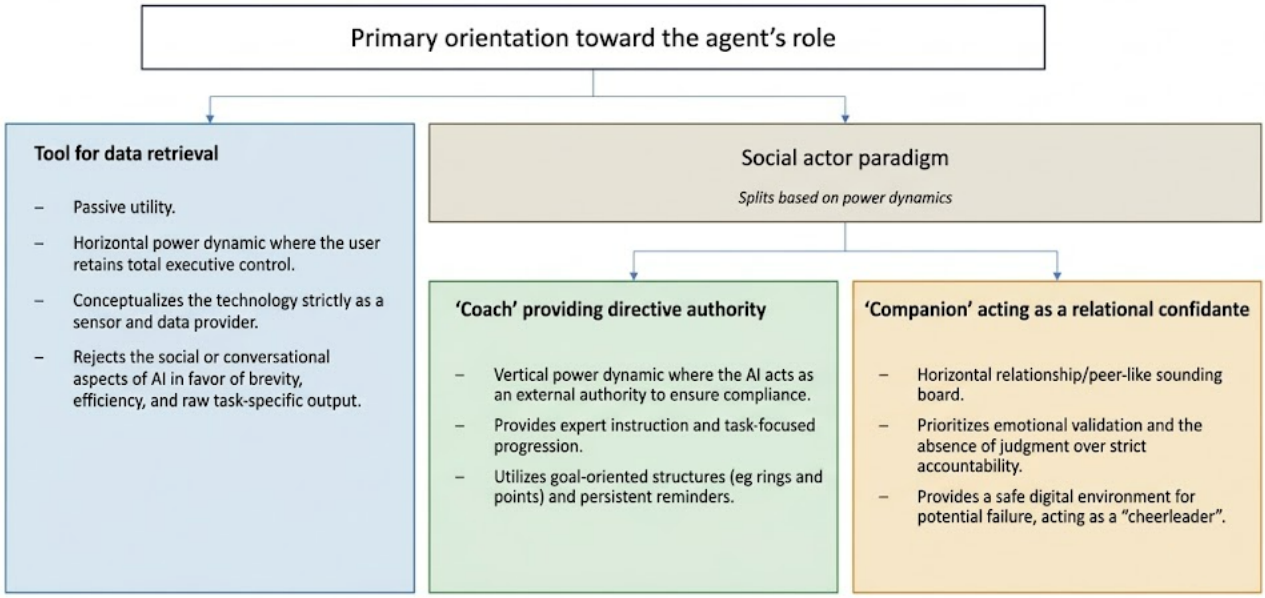
When seeking health information, participants used a sophisticated, multisource approach characterized by conditional trust. This often involved a rigorous verification process for search engine results, where participants explicitly avoided relying on top hits alone (eg, P8). P20 elaborated that the priority was honesty, even if it resulted in complexity:

> *I always keep reading further... I'll read two, three things past that—sometimes it'll be the same... and sometimes it won't… it's got to be honest. Some things cannot be simplified. It's going to take some time and energy.*

However, this digital searching was balanced by participants who relied on nondigital sources. Participants grounded their trust in established medical authority (eg, P2), curated traditional media such as books and magazines (eg, P11), and their own somatic intuition, prioritizing what their bodies told them over external data (eg, P14).

Attitudes and Preferences Toward AI in Health

The majority of participants (14/20, 70%) demonstrated a pragmatic willingness to try an AI-powered coach. Even in the case of skepticism, outright rejection was rare and participants were curious and wished to give it a chance to prove its utility.



Role of AI

The analysis of participant preferences regarding the AI's role revealed distinct patterns in how users negotiate autonomy and support. Participants viewed AI in different ways based on desired power dynamics: a relatively passive "tool" (n=9, 45%), a directive "coach" (n=8, 40%), or a relational "companion"

XSL•FO
RenderX

(n=3, 15%). Figure 1 maps this visual typology, with individual participant classifications and supporting evidence provided in Multimedia Appendix 3.

Figure 1. Visual typology of AI roles: mapping the tool, coach, and companion.

Many participants (6/20, 30%) were optimistic that an AI coach could provide essential accountability. A substantial number (n=6, 30%) explicitly desired that the AI coach "push" them, tracking specific metrics, such as workout frequency and weightlifting (as exemplified by P2). They preferred this push to be supportive rather than punitive, as P9 envisioned:

> *If you had an AI app and there's some avatar that you talked to who said "hey did you do your walk today? Well, why not?" I think encouragement rather than admonishment would be better.*

The access to exercise data on the move was considered helpful for influencing workout length and intensity. The use was informational but its hypothesized use in session also had the perspective of accountability. P3 felt it could be useful to track distances against targeted norms:

> *If I was walking more than resting... am I going as far? ... Especially if I'm in a new place, like if I'm traveling and I don't know the route as well.*

The facet of accountability was also present in pushing users to do more, as with a real personal trainer. P18 lucidly explained a future scenario of use:

> *Especially if you're wearing an Apple watch, it would know your heartbeat ... exactly how much exertion you're putting into it. It could help keep track of your repetitions and give you advice... Let's say, I said, I'm ready to quit, and if it said, Wait a minute. You need another set of repetitions on certain things that would be great, you know. I think it would help you do it would help make sure you got you got to, because it's easy to say I've done enough when you don't have a personal trainer there.* [P18]

P11 was even more upfront about desiring an AI coach that was blunt rather than soft:

> *As opposed to being nice and saying, "oh, I think you can do better." No, I need someone that says, "come on, you're half-assing it." So, I don't need a drill sergeant, but I need something more than a soft person.*

The personal monitoring could also be in the form of informational suggestions, such as for sleep and enjoyable activities (eg, P13). Participants valued the ability to ask follow-up questions in a "back and forth" dialogue with a CA. For some, this dynamic shifted the AI's role from a strict instructor to a supportive peer. P8 explained:

> *Coach is a little strong... I would like to think it is maybe a companion, an associate... somebody who is sympathetic, empathetic but holds me to it.*

On the other hand, some participants could only perceive AI as a utilitarian tool, viewing it as inherently impersonal. P3 felt that her interactions would be task-specific only:

> *I think I would just be interested in the goal 'tell me how far I've gone.*

She, however, appreciated the convenience of querying health statistics via natural language. Participants such as P10 wholly rejected the concept of an AI health coach for either motivation or information. Ultimately, even those receptive to AI motivation frequently alternated between viewing it as an active coach and a passive informational tool.

Personalization

A strong desire for personalization was expressed by 11 (55%) participants. They wanted an app that would adapt to their specific health conditions and allow them to control their own goals. For instance, P1 wanted any advice to be catered to her situation, schedule, and current weather and not "generic walk 10,000 steps" advice. Similarly, P19 described desired flexibility in setting goals:

XSL•FO
RenderX

> *I would want to be able to set my own goals... be able to go in and adjust it if I'm having a bad day.*

Others expressed interest in getting personalized notifications (eg, P3), while P13 and P17 were enthusiastic about guidance based on specific limitations, such as mobility issues. There was also a desire for a multistage CA that adapted its complexity to each user's needs in "stages" proceeding gradually toward providing detailed research information (eg, P6).

However, some participants felt that current generative AI (GenAI) models lacked the contextual knowledge required to answer highly specific questions. P10 explained that desired specificity makes her prefer trusted websites over GenAI answers:

> *All it could give me would be just generalisations. I've got specific questions. How much does it cost to do this? How many days would I have to wait for this? Google AI would have no way of knowing those answers.*

Some participants wanted very strong referencing of the information that the AI would provide. P6 noted that giving, "a detailed list of even academic references...would be perfect," a sentiment echoed by P17 and P18. P5 wished that the AI be very "science based," share citations carefully, avoid "dumbing down" information, providing very detailed reasons alongside a quick summary:

> *I would want it to give me a reason...the important sources used to come to this conclusion... If you get that type of information, and they don't put their citations with it, then you don't know where the science is coming from.* [P5]

When asked about preferences for a hypothetical assistant, most participants would prefer a conversational assistant integrated into a device they already use, such as a smartphone or smartwatch, rather than a separate, standalone device. A minority (n=2, 10%) explicitly preferred multiple devices, but the rest preferred it to be included within their phone. Regarding notifications, a small number (n=2, 10%) preferred a "pull" model (user-initiated), whereas 4 (20%) participants explicitly valued "push" reminders as a necessary mechanism for accountability.

Visual Presentation

Embodiment was not a strong point of contention for most participants, with several explicitly expressing indifference toward it. However, among those who cared, 8 (40%) participants showed a clear preference for embodiment, while only 1 (5%) preferred a nonembodied CA. Furthermore, every participant showed at least some strong preferences among different avatar choices, displaying a clear preference for relatability. The majority (13/20, 65%) explicitly preferred human-like avatars, rejecting robot avatars for being unrelatable, using words such as "artificial" or "sci-fi" to describe them.

Within the human category, preferences were split by age. Some participants preferred older avatars, perceiving them as peers with shared experience while others preferred younger avatars, associating youth with up-to-date health knowledge, as in the case of P15:

> *I would prefer the younger one... because they might be more up-to-date... and I might feel that they would be more encouraging.*

Beyond age, participants expressed a specific preference for physical attainability, often rejecting avatars with "sculpted" or hyperfit physiques as discouraging (eg, P18). P5 ridiculed the notion:

> *I know zero ladies that have abs like that at her age.*

Similarly, P9 rejected aspirational avatars:

> *If the app were some guy with a six pack... that's just BS... I think more of a peer.*

This sentiment was not universal, though; in contrast, P17 wished to see aspirational physiques in the avatar:

> *I'd like to see what they do if I can do that.*

The embodied version of the AI also had an impact on personalization. Some participants wanted to feel a connection with their AI coach. P13 expressed:

> *I would like for it to more like a confidante... [Pointing to older male coach avatar] This picture feels like they're interested in what I have to say. He's the sort of guy I feel like I could talk with. I could sit down and have a beer with.*

Skepticism and Distrust

AI evoked skepticism among many due to a number of reasons, the most important among them being accuracy and the "black box" nature of the technology. Threat to privacy and perceived loss of independence were other concerns.

Adverse previous experiences often led to concerns about poor accuracy. An illustrative experience was that of P4, who had played around with ChatGPT:

> *The struggle I had when I was trying to get it to do exactly what I wanted it to do. A lot of times when it would fail at doing something, I didn't know its limitations or it couldn't figure out what I was trying to say.*

Similarly, P16 was "wary" for reasons of accuracy and information sources:

> *It pulls up a lot of things from a lot of places. I don't know how accurate everything is.*

P8 stressed the importance of accuracy over response speed:

> *If you want to sacrifice detail, accuracy and completeness for efficiency—for making it quick and easy—you're going to end up with a lot of stupid people, which we already have.*

The gradual creep of AI into daily life also caused discomfort, with some viewing it as an encroachment on independence. This discomfiture was expressed powerfully by P8 who questioned AI creators' underlying motives:

XSL•FO
RenderX

> *I want to question who's putting this together, who is creating. Am I looking at Zuckerberg... Musk? Are these people that I would trust on other things? ... do they have a motive other than just information for me... I know Big Brother's out there. I don't the idea of having a device that would listen to everything I say or do bothers me.* [P8]

Overall, there was a prominent lack of trust for AI among participants. Even those who had used a GenAI-based CA directly exhibited visible unease (eg, P20). Despite acknowledging its potential usefulness, P15 regarded herself as "suspicious" of GenAI and untrusting of its answers:

> *When I ask a question I always go down further, because I don't want to read the AI answer. I want to read the other answer.*

This caution frequently extended to fears regarding the prevalence of digital scams and phishing (eg, P9).

Discussion

Areas of Improvement in App Design for Older Adults

Matching Accessibility and User Needs

In this study, we found most participants to be current users of smart devices, but despite their comfort, there was a discrepancy between their general familiarity with apps and their actual comfort in practice, primarily due to accessibility issues. STAM [22] explains this discrepancy. When the procedural demands and learning curve of an app exceed users' cognitive or sensory thresholds, the perceived utility of the technology collapses. This resonates with previous work done by Vaportzis et al [48] on older adults working with tablet computers. Even older adults who are adept current users of technology would prefer simplicity: their usage alone does not mean that the apps meet accessibility needs.

Participants in our study appeared to be developing adaptive strategies to cope with a fast-changing technological landscape in conjunction with their own cognitive and sensory declines. STAM explains this retreat to familiar desktop computers for substantive tasks as a rational calculation (not a digital deficit) with users actively filtering out complex apps to manage age-related barriers [22]. Excess features contributed to cognitive overload, creating a steep learning curve [48] that acted as a hard filter between basic device usage and mastering new health apps. This burden is compounded by hardware seen as failing to accommodate aging users [12]. While previous literature suggests a potential benefit for voice interfaces [32], our participants expressed mixed preferences, suggesting that giving users more interface options might be best.

Our typology also revealed that for some participants oriented toward the tool archetype, the demand for interface simplicity did not equate to a desire for simplified content. These expert users expected granular, high-level data, demonstrating that accessibility in mHealth should streamline navigation without diluting the scientific complexity of the information provided. This aligns with previous literature cautioning against oversimplification [14].

Social Connectedness

Among our predominantly well-educated sample, socialization and accountability were significant drivers, although whether this generalizes to more diverse populations warrants further investigation. SDT's tenet of relatedness [49] illustrates why, for many, the exercise itself was secondary to the community interaction it provided. Facilitating these meaningful social connections acts as a vital relatedness-supportive mechanism [50]. Solitary app mechanics of most individual-centric mHealth tools fail to replicate this sense of communal security.

While digitizing social connection offers potential, it often conflicted with preferences for privacy and meaningful interaction. SST [26] accounts for this resistance, positing that as older adults prioritize emotionally meaningful relationships, mechanisms that broadcast personal data to peripheral networks conflict with their preference for selective intimacy. This theoretically contextualizes findings on social comparison by Koivisto and Malik [10] and Orji [27]. Thus, successful interventions would do well to shift from individual-centric models to community-centric ones that facilitate this safety net without enforcing high-pressure, privacy-invading competition.

Functional Independence

The older adults' emphasis on maintaining a high degree of functional independence for their full lifespan also resulted in more pragmatic reasons for adoption of health apps or wearables. However, monitoring of step count and heart rate is known to have a contributing effect on increasing levels of PA [51]. It thus might be advisable to consider in mainstream health apps features for monitoring current chronic conditions to attract older users. Moreover, daily routines too warrant inclusion. Many participants got PA done as part of daily activities, such as walking their dog. An app would connect more with people if it discussed PA as part of their daily life rather than as workout routines alone.

Gamification contributed to encouragement for many participants and also added to accountability. This is encouraging given the proven effectiveness of gamification in improving health interventions for older adults [52]. However, extrinsic feedback loops in the form of tracking and gamification were also disliked by some participants despite diligence in performing PA. Here, SDT is explanatory because it predicts that those exercising higher autonomy will reject these as patronizing or irrelevant [49,53]. The taxonomy of motivational behaviors by Ahmadi et al [50] categorizes this exact friction as an autonomy-thwarting mechanism. Conversely, participants adopting the "coach" orientation actively requested strict accountability and persistent prompts. This is also consistent with SDT because actively choosing a directive system to enforce personal discipline remains an autonomous decision and is a delegation. The divergence of participant needs on the complexity of PA tracking measures—optimization vs simplicity—also has implications. PA apps aimed at the older demographic would thus do well to have a simple mode with limited tracking and reduced clutter while allowing for an expanded mode that affords detailed tracking, because complex apps have shown no additional benefit over simple pedometers for PA, as found in a systematic review and meta-analysis [51].

XSL•FO
RenderX

Personalized Interactions

The findings indicate that participants possess distinct and often contradictory requirements that necessitate personalization. The data reveal divergent design preferences that cannot be adequately addressed by a single, static app. A similar divergence appears in gamification preferences, where participants were quite polarized, although slightly more expressed motivation from game elements. Among those motivated by gamification, the underlying drivers varied significantly between those seeking competition and those interacting with features pragmatically to track habits. Those who actively rejected gamification viewed it as patronizing or irrelevant. A standardized strategy, such as a default leaderboard, thus risks actively demotivating the intrinsic and routine-driven groups. Avatar choices too are very divergent, and a wide range of choices are better if embodiment is used because individual preferences are strong.

These conflicting preferences suggest that adoption for this demographic is conditional on the ability to tailor the experience. Under SDT [49], the widespread desire to set one's own goals reflects a fundamental need to preserve autonomy, driving participants to reject generic, prescriptive advice. Providing these meaningful choices operates as a core autonomy-supportive mechanism [50]. Consequently, implementing principles of autonomy support is critical, specifically the provision of choice and the minimization of external pressure [49]. Our findings also indicate that rigid system-defined metrics can further anxiety. Inflexible mandatory targets such as daily step counts can act as competency-thwarting features [50] that undermine user confidence. Therefore, streaks and targets that flexibly adjust to user circumstances may help avoid imposing undue pressure.

Future Implications for AI Integration and the Role of Trust

The study has a number of findings about the perception of AI that would be instrumental to future designers of apps using AI for aiding older adults in the context of PA. We found that participants were willing to try AI-based systems but nursed inherent skepticism. There are 2 major points of discussion concerning the use of AI by older adults. The first is on their hypothesized use cases, and the second is on the prerequisites that massively impact their adoption and perception of AI.

AI in Health Apps: Tool, Coach, and Sometimes Companion

The inductive typology that emerged from the data clearly aligns with functional distinctions in existing human-computer interaction literature. Specifically, it identifies whether participants viewed the AI as a "tool" for data retrieval [54], or following the social actor paradigm [33], as a "coach" providing directive authority [55] or a "companion" acting as a relational confidante [56].

The study shows that older adults are open to increased AI functionality in their apps. A remarkable proportion of the participants wished to feel a sense of being accountable to someone for their PA; even motivation could be attributed to discussions with an intelligent CA. Many use cases were informational but their presumed use was different from search engine behavior because they expected the CA to remember detailed personal context and provide information; this use case, although informational, is closer to that of a personal assistant for health. Previous literature too has found social support to be very helpful in increasing PA among older adults [57]. Their liking for gamification within apps was part of such motivation. However, gamification alone lacks a social component. While the need for social accountability is ideally satisfied by friends and family or even through personal trainers, many older adults lack them; it can be hypothesized that social support CAs could assist in such contexts, which could also help in alleviating loneliness [58]. Research has found that quality goal-setting practices, self-efficacy, and social support predict PA among older adults [59]. These can be facilitated by CAs, and this study too finds older adults to be willing to use them for these purposes. The CA having relatable embodiment and personality might help further.

However, based on our findings, health apps, especially with AI, have to take care not to negatively affect feelings of self-efficacy among older adults. We resonate with Klasnja et al [60] in that the AI should have the provision of modularity features—allowing users to use it as coach, tool, or companion. Providing this modularity ensures the app can dynamically satisfy the differing theoretical drivers of our participants—whether seeking accountability (SDT), relatedness (SST), or pure usability (STAM)—thereby protecting self-efficacy and respecting each user's distinct needs.

Trust and Privacy as Foundational Prerequisites

Trust emerged as a foundational prerequisite for adoption, linking privacy concerns, AI skepticism, and information preferences. Under STAM [22], a lack of trust acts as a hard stop for adoption; if an app feels unsafe, its usability and intended utility are lost. Our participants viewed AI as a tool requiring human oversight rather than as an autonomous authority. This heightened sensitivity aligns with research indicating that older adults with higher educational attainment are significantly more likely to raise data privacy concerns than their peers [28]. The findings on information accuracy and privacy are corroborated by other studies [61].

Trust is also closely related to accuracy and algorithmic transparency. The participants' distrust of AI stems directly from a practical awareness of GenAI's propensity for hallucinations [62]. Inaccurate AI poses severe hazards in health care, and older adults require systems that make their reasoning visible. This demand aligns closely with explainable AI frameworks tailored for older demographics [63,64]. Participants expected the technology to justify its outputs rather than act as an unquestionable authority [64]. Their rejection of dumbed-down summaries serves as a practical test of this requirement. They consistently preferred referenced explanations over simplifications because obscuring the source data is often perceived as a breach of honesty. Designing these explanations to be both transparent and accessible [63] forms the foundation necessary to earn their trust.

XSL•FO
RenderX

Preliminary Design Considerations

On the basis of participants' stated preferences and hypothetical reactions, we propose the following considerations for future designers of PA apps aimed at older adults. As these are derived from interview data and visual probe responses rather than observed usage behavior, they serve as preliminary guideposts rather than definitive rules.

1. Maintenance: Algorithms aimed at older adults may benefit from identifying a steady routine and rewarding consistency rather than aggressively pushing for continuous increases.
2. Social accounting: Designs could explore enabling easy sharing of physical activities and integrating social cues as a proxy for real-life social contact.
3. Relatability: More participants preferred age-appropriate avatars with average body types, suggesting these visual defaults may reduce psychological distance. This preference may be varied by cultural background and familiarity with digital agents.
4. Transparency: Providing direct links to reputable sources allows users to verify recommendations independently, supporting explainable AI principles.
5. Flexibility: Interfaces that support graceful failure states, such as allowing users to modify success criteria or auto-pause streaks during illness, better accommodate changing user physical realities.
6. Screen constraints: Developers might consider offering a companion view on tablets or desktops for complex data review while reserving mobile phones for passive tracking.
7. Passive data collection: Prioritizing automated data collection (eg, via wearables or sensors) can bypass the physical friction of manual entry.
8. Minimal interface changes: Participants expressed frustration with shifting layouts, suggesting that established navigation flows be changed only with substantial care.
9. Lifestyle integration: Rather than framing PA exclusively around structured workouts, apps should recognize and validate daily functional tasks (eg, gardening and housework).

Limitations

This study has several limitations. The participant sample consisted predominantly of individuals in an urban area of the Midwestern United States who are well educated, relatively financially secure, and relatively ethnically homogeneous. Importantly, they possess a high baseline of technological literacy that likely exceeds that of the broader older adult population. As a result, key findings regarding how comfortable participants were with technology, their openness toward AI's roles, and their specific skepticism toward AI may not apply to older adults with different educational, economic, or cultural backgrounds. We caution against overgeneralizing these findings; the nuanced views on AI observed here may represent a "best-case scenario" and cannot be automatically transferred to more diverse or underserved populations who face deeper digital divides. The study also relied on recall and self-reporting with participants reporting their own PA and technology use; an important caveat is that participants' reported satisfaction with their PA levels may be influenced by social desirability, particularly given that they were recruited from an academic community and interviewed by university researchers. Self-report of PA is known to be susceptible to overestimation [65]. While participants expressed confidence in their activity levels, the absence of objective measures (eg, accelerometry) means we cannot confirm whether their activity meets recommended thresholds.

Finally, the discussion regarding AI agents was based on static visual probes and hypothetical scenarios rather than real-world use; participants' trust and engagement might differ if they were using a functioning system over a long period. Visual probes in the future too could feature more diverse human avatars.

Conclusions

In this study, we investigated the current usage of technology for PA among older adults and their attitudes toward AI usage. We found that older adults are primarily motivated by the desire to sustain functional independence and meaningful social connections. They sought maintenance of baseline health rather than chasing continuous improvement. While existing apps and wearables were widely adopted, rigid navigation flows, cognitive overload, and a mismatch with user needs continued to act as significant accessibility barriers. Most participants were willing to try AI-assisted technology but their expectations varied. They viewed it either as a passive user-led "tool," a directive "coach" for strict accountability, or a relational "companion" for empathetic support. Older adults also possessed divergent views on gamification and tracking, and while the majority found it motivating, a significant minority found it condescending or anxiety inducing. Visual design preferences for CAs also varied widely, including split preferences on age, physique, and human versus nonhuman representation. Clearly, future AI apps should consider offering more modularity, personalization, and optionality.

Skepticism among older adults remained high due to pervasive concerns over data privacy, algorithmic hallucinations, and a perceived threat to user independence. AI that is personalized, transparent, and privacy protecting and that provides detailed referencing and explainable outputs when necessary is much more likely to be trusted. Greater use of AI-supported technologies for PA ultimately hinges on gaining user trust.

Acknowledgments

The authors thank the participants for their time and insights. The authors declare the limited use of generative AI in the research and writing process. Generative AI (GenAI; OpenAI's DALL-E 3 used through ChatGPT 4.0) was used to create the visual avatars for the interview probes. According to the GAIDeT (Generative AI Delegation Taxonomy) [66], the following tasks were assisted by GenAI tools under full human supervision: literature search and systematization, proofreading and editing, and

Abstract

Background: Older adults with chronic joint pain often exhibit decreased mobility. Daily walking measures are being increasingly used in aging research as objective indicators of mobility.

Objective: In this study, we aimed to examine the effects of a 12-week hybrid exercise-based program on daily-life walking characteristics.

Methods: A total of 59 community-dwelling older adults (aged ≥65 years) with mild to moderate knee and/or low back pain were randomized to either a hybrid exercise group or an educational control group. Daily-life walking was monitored using an ankle sensor. Daily observation data were collected within 2 planned 7-day windows. Primary parameters included activity volume and gait characteristics. Statistical analyses were conducted based on a modified intention-to-treat principle using linear mixed-effects models, with a per-protocol set used for sensitivity analyses.

Results: The mixed-effects analysis based on the modified intention-to-treat principle (n=52 participants; 696 observations) suggested an effect of the intervention on improving walking quality, particularly step length (β=2.39 cm; *P*=.04; Hedges *g*=0.493), with a smaller effect with borderline statistical significance observed on improving walking speed (β=0.05 m/s; *P*=.06; Hedges *g*=0.496). Cadence, daily distance, daily steps, active energy expenditure, and accumulated 3 or more metabolic equivalent of task activities showed no clear difference between the groups. In the per-protocol sensitivity analysis (n=44), the same directional pattern of improvement was observed for step length (β=1.95 cm; *P*=.13; Hedges *g*=0.365) and walking speed (β=0.04 m/s; *P*=.14; Hedges *g*=0.368); however, the estimates were imprecise.

Conclusions: A 12-week hybrid exercise program may improve the quality of daily-life walking, with the clearest effect observed on step length. Given the attenuation after multiplicity-aware interpretation and in sensitivity analyses, these findings should be interpreted as suggestive rather than definitive.

KEYWORDS

hybrid video-guided multicomponent exercise program; randomized controlled trial; gait; active energy expenditure; pain

Introduction

Walking function maintenance is a key target for preserving independence in older adults because gait-related measures such as walking speed have been reported as early and strong predictors of subsequent decline in instrumental activities of daily living among community-dwelling older adults [1]. Musculoskeletal pain is a major barrier to maintaining walking function in older adults [2,3]. In Japan, approximately 42.2 million adults (41.2%) experience musculoskeletal pain, with 9.1 million (8.8%) reporting that the pain interferes with their daily activities [4]. The national burden of low back, hip, and

XSL•FO
RenderX

knee pain is projected to increase up to 2055 [5]. These burdens are particularly pronounced in older adults. In Japan's population-based ROAD (Research on Osteoarthritis Against Disability) study of community-dwelling people aged 60 years and older, the prevalences of radiographic knee osteoarthritis (Kellgren-Lawrence grade≥2) were 47.0% and 70.2% in men and women, respectively [6]. In the related LOCOMO (Longitudinal Cohorts of Motor System Organ) study, the prevalence of knee pain was 32.7%, and that of lumbar pain was 37.7%; overall, 12.2% of the participants reported both knee and low back pain concurrently [7]—the very combination targeted by the present study. Scalable approaches to musculoskeletal pain are therefore urgently needed to prevent pain-related functional decline in aging societies.

Numerous randomized controlled trials have demonstrated the effectiveness of multicomponent exercise programs in relieving symptoms and improving function in individuals with chronic knee and low back pain. For knee pain, programs combining stretching, strengthening, and aerobic exercises improve pain and physical function [8]. For low back pain, similar improvements require more than exercise programs alone; interventions integrating exercise with pain coping and behavioral skill training have shown sustained benefits [9-11]. Although many of these interventions were delivered under professional supervision, the high prevalence of knee and back pain in the older adult population highlights the need for more accessible exercise programs [12].

To improve access, audiovisual programs and remote digital interventions have been evaluated for musculoskeletal pain management. These include internet-delivered exercise programs with pain coping skill training for chronic knee pain and digital care programs for chronic low back pain [13,14]. However, adherence to home exercise programs declines over time. Key barriers to sustained participation include symptom flare-ups, fear of worsening pain, limited feedback or support outside of supervised settings, and difficulty integrating exercise into daily routines despite the flexibility of video-based delivery [15-17]. These practical constraints suggest that a hybrid program in which participants perform video-guided exercises during on-site sessions with staff support may be more effective.

Daily walking measures obtained in real-world settings are increasingly used in aging research and complement laboratory-based assessments as objective indicators of mobility [18-20]. Reference values for daily-life walking parameters have been reported in the Japanese population [21], and daily-life walking speed, as assessed using smartphones, has been used to evaluate frailty [22]. Daily-life walking speed is increasingly used as an objective indicator of mobility, disability, and other adverse health outcomes in older adults [23,24].

Thus, in this secondary analysis of data from a randomized controlled trial, we aimed to examine whether a hybrid exercise-based intervention improved objectively assessed daily-life walking outcomes. In the parent randomized controlled trial, participants were allocated to either a hybrid multicomponent exercise program (video-guided exercises with staff assistance during twice-weekly on-site sessions) or a once-a-week face-to-face class. Primary symptom outcomes will be reported separately. We also sought to compare the effects of the two programs on objectively assessed daily-life walking outcomes.

Methods

Study Design and Setting

This study involved a secondary analysis of data from a randomized controlled trial that evaluated a hybrid, exercise-based program targeting knee and low back pain. Participants in the intervention group attended on-site sessions involving video-guided exercise with staff assistance, whereas participants in the control group attended weekly face-to-face educational lectures regarding knee and low back pain. The trial was conducted at a community-based exercise facility in Iruma, Japan, and the study-related procedures took place at Saitama Medical University. The study period was from June 10, 2025, to October 17, 2025.

Participants

The study participants were community-dwelling adults living in the vicinity of the Karada Ugoki Kaifuku Center, Iruma. All participants who were randomized to either the intervention or control group and who contributed any valid daily-life walking data were eligible for inclusion. We included older adults aged 65 years and older who were able to walk independently and access the facility and experienced mild to moderate knee and/or low back pain, with pain intensity rated as less than 8 on a visual analog scale (VAS) from 0 to 10. The exclusion criteria were inability to walk independently, severe joint pain (VAS score ≥8), presence of medical conditions such as neurological or respiratory disease that made participation in the exercise program inappropriate as judged by a physician, and difficulty with decision-making because of dementia or impaired consciousness.

Sample Size

The sample size was determined based on the primary outcomes of the parent trial, specifically the Roland-Morris Disability Questionnaire and the Western Ontario and McMaster Universities Arthritis Index. A sample size of 20 participants per group was calculated to provide 90% power to detect the expected effect based on the mean intergroup difference and SD reported in a similar randomized controlled trial [1,2,25,26]. To allow for attrition and missing outcome data, the total recruitment target was set at 60 participants, comprising 30 participants per group. A separate sample size calculation was not performed for this secondary analysis.

Randomization and Blinding

Participants were randomly assigned to the intervention or control group in a 1:1 ratio using a computer-generated random sequence prepared by the Department of Biostatistics, Saitama Medical University Graduate School of Medicine. Specifically, the sequence was generated using the SAS software (PROC PLAN statement; SAS Institute) with a fixed random seed, and randomization was performed using permuted blocks with a block size of 6. Participant enrollment was conducted by the

XSL•FO
RenderX

second author (T Arai), whereas group assignment was implemented by the Biostatistics Group at Saitama Medical University and was performed independently of the intervention team. Blinding of participants and intervention staff was not feasible due to the nature of the interventions; however, the outcome assessors for performance-based measures were blinded, and questionnaire outcomes were self-reported.

Baseline Measures

Baseline characteristics for which data were collected in the parent trial included demographics (age and sex), anthropometrics and body composition (height, body weight, BMI, and skeletal muscle index), physical performance (maximal grip strength, standing time on one leg, and comfortable and maximal walking speed), pain and symptom measures (the low back and knee pain VAS score, Roland-Morris Disability Questionnaire score, and Western Ontario and McMaster Universities Arthritis Index subscale and total scores), and health-related questionnaires (25-question Geriatric Locomotive Function Scale, Kihon Checklist, Geriatric Depression Scale, and EQ-5D index).

Interventions

Participants in the intervention group received an on-site exercise program delivered through the Curves personalized exercise support system, which aimed to alleviate knee and low back pain through individually prescribed video programs with staff present to support participation and ensure safety. The program consisted of 21 distinct exercises comprising 12 stretching exercises and 9 muscle strengthening exercises. Stretching was performed to the maximal comfortable range of motion, with each of the 12 positions held for 30 seconds. Regarding muscle strengthening, upper-limb and lower-limb exercises used body weight resistance or auxiliary equipment such as elastic bands and a rubber ball, with intensity adjusted to a “somewhat hard” perceived exertion level. Strengthening exercises were performed for 30 seconds each at a speed based on the participants’ subjective intensity. The planned frequency and duration were 2 sessions per week for 12 weeks. The specific content and progression rules were updated based on the participants’ exercise proficiency and visit frequency according to age. Participants initially started with 15 exercises and progressed to performing the full 21-exercise program after 4 weeks. Staff monitored participant responses and implemented safety protocols, including discontinuing exercise for a specific body part if acute pain occurred and adjusting movements to a pain-free range of motion if pain was present. The control group received on-site educational lectures on knee and low back pain once weekly during the intervention period, and these participants were offered access to the intervention program after the completion of follow-up assessments.

Secondary Analysis Outcomes

This secondary analysis focused on daily-life walking outcomes derived from an ankle-worn activity monitor, WAlkX (Sanka). We analyzed daily activity volume outcomes, representing the daily accumulation of distance, steps, active energy expenditure, and activities graded at 3 or more metabolic equivalents of task (METs). In addition, we analyzed gait characteristics, representing the daily average values for walking speed, cadence, and step length. Participants were asked to wear the device continuously unless it caused discomfort.

The device was worn continuously during waking hours throughout the monitoring period, including during the on-site sessions; participants were not asked to remove it. Because the supervised sessions comprised video-guided multicomponent exercises performed in place rather than continuous overground walking, in-session activity did not generate the gait bouts detected by the daily-life walking algorithm and did not contribute to the step count or gait parameters. Therefore, the reported outcomes reflect habitual out-of-session daily-life walking.

The preintervention window was the 7 days starting 1 day after device placement. The postintervention window was the 7 days immediately preceding each participant’s last observed monitoring day, capturing late-program or end-of-program daily-life walking. The timing of the last monitoring day relative to the scheduled program end date varied across participants (in most cases, it clustered near program completion, with earlier cessation of monitoring in some participants), reflecting differences in device return and wear adherence.

Adherence, Protocol Deviations, and Safety

Adherence was quantified as the number of sessions attended and the percentage of prescribed sessions completed during the intervention period, with adequate adherence for the per-protocol analysis defined as completion of 80% to 120% of the prescribed sessions. Protocol deviations and adverse events were monitored throughout the study.

Statistical Analysis

For this secondary analysis, we use the term “modified intention-to-treat” (mITT) analysis because it included all randomized participants who contributed at least one valid daily-life walking observation in both windows rather than all randomized participants. Daily-life walking outcomes were analyzed using repeated-measure linear mixed-effects models (LMMs) incorporating all available daily observations from participants who contributed at least one valid observation in both the pre- and postintervention windows. The LMMs were prespecified based on the repeated-measure data structure rather than selected from a normality test of the outcome distributions. Daily observations were extracted from 2 planned 7-day windows anchored to the monitoring period. The preintervention window was defined as the 7 days starting 1 day after participants began wearing the device (ie, excluding the first day to avoid potential reactivity or partial wear effects). The postintervention window was defined as the 7 days immediately preceding the last observed monitoring day for each participant. Days with no recorded step counts (steps=0) were treated as missing daily walking observations and were excluded from model fitting. As a sensitivity analysis, we conducted a per-protocol set (PPS) analysis based on the trial ledger; we included participants classified as PPS eligible. Intervention effects were estimated using repeated-measure LMMs, with the primary parameter of interest being the group × phase interaction term, interpreted as a difference-in-differences (DID) estimate.

XSL•FO
RenderX

For each outcome, we fitted a repeated-measure LMM including fixed effects for group, phase, day in window, and the group × phase interaction, with a participant-specific random intercept.

Model estimates are reported as regression coefficients with 95% CIs. Models were fitted using restricted maximum likelihood in Python (version 3.14.0; Python Software Foundation) using statsmodels (version 0.14.6) with Pandas (version 3.0.1), NumPy (version 2.4.2), and SciPy (version 1.17.1).

Ethical Considerations

The study was conducted in accordance with the principles of the Declaration of Helsinki and the relevant Japanese ethical guidelines. It is reported in accordance with the CONSORT (Consolidated Standards of Reporting Trials) 2010 statement. The protocol was approved by the Saitama Medical University Institutional Review Board (approval 2025-004; May 24, 2025). The trial was registered in the University Hospital Medical Information Network Clinical Trials Registry (UMIN000057169) [27]. All participants provided informed consent prior to enrollment.

Results

Overview

The baseline characteristic data of participants in the parent trial are summarized in Table 1. Overall, 60 participants were assessed for eligibility in the present study; however, 1 withdrew after providing consent. Thus, 59 participants were randomized, with 30 assigned to the intervention group and 29 assigned to the control group. The flow of study participants is summarized in Figure 1 (CONSORT flow diagram).

[f]LOCOMO-25: 25-question Geriatric Locomotive Function Scale.

[g]GDS: Geriatric Depression Scale.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram of participant allocation, follow-up, and details of analysis sets, including the final modified intention-to-treat and per-protocol set (PPS) mixed-effects samples after the planned missing data handling for daily walking observations.

A total of 56 participants contributed at least one valid daily observation within the planned 7-day pre- and/or postintervention windows. Of these, 54 participants (intervention: n=29; control: n=25) were mITT eligible (ie, they contributed at least one valid daily observation in both windows). Three randomized participants contributed no valid

XSL•FO
RenderX

activity monitor data within the planned windows, and 2 further control participants had observations from only 1 window. Of the 54 mITT-eligible participants, 52 (intervention: n=29; control: n=23; 696 daily observations) contributed analyzable observations to the fitted mixed-effects models after treating days with no recorded steps (steps=0) as missing. The 2 remaining control participants had valid prewindow days but no analyzable (nonzero steps) postwindow days; therefore, they could not contribute a within-participant pretest-to-posttest contrast and were not estimable in the fitted models.

In the intervention group, the median number of sessions attended was 23 (IQR 21 - 24) over the 12-week period. As a sensitivity analysis, a PPS was defined based on the trial ledger. This yielded 47 PPS-eligible participants (intervention: n=27; control: n=20), of whom 44 contributed at least one valid daily observation in both windows (intervention: n=26; control: n=18).

Mixed-Effects Analysis Using All Available Data

In the mixed-effects models using all available daily observations, 52 participants contributed 696 daily observations across the 2 planned windows (before and after the intervention). The PPS sensitivity analysis contributed 44 participants and 595 observations.

In the mixed-effects models using 696 daily observations from 52 participants, the intervention was associated with a directional effect toward better gait quality, which was most clearly observed for step length. The DID estimate for daily-life step length was 2.39 cm (*P*=.04; Hedges *g*=0.493), whereas walking speed showed a smaller effect with borderline statistical significance (β=0.05 m/s; *P*=.06; Hedges *g*=0.496). Cadence did not differ clearly between the groups (β=1.26 steps per minute; *P*=.50). Daily steps and active energy expenditure also did not significantly differ between the groups (β=–51.0 steps per day and *P*=.92; β=4.84 kcal per day and *P*=.83). The effects of the intervention on daily distance and accumulated 3 or more MET activities were likewise null (β=0.08 km per day and *P*=.75; β=0.08 MET hours per day and *P*=.81; Table 2). As the gait quality outcomes were assessed alongside multiple related outcomes, these findings were interpreted as signals rather than as definitive confirmatory evidence.

Table . Results of the modified intention-to-treat analysis using mixed-effects models with all available daily observations.

Outcome variables	Participants, n	Observations, n	DID[a] coefficient (SE; 95% CI)	*P* value	Hedges *g*[b]
Distance (km/d)	52	696	0.08 (0.26; −0.42 to 0.59)	.75	0.076
Steps (steps per d)	52	696	−51.00 (521.02; −1072.21 to 970.20)	.92	0.000
Acal[c] (kcal per d)	52	696	4.84 (22.05; −38.38 to 48.06)	.83	0.100
MET[d] h (MET h per d; ≥3 METs)	52	696	0.08 (0.32; −0.55 to 0.71)	.81	0.079
Speed (m/s)	52	696	0.05 (0.03; −0.00 to 0.10)	.06	0.496
Step length (cm)	52	696	2.39 (1.18; 0.09 to 4.70)	.04	0.493
Cadence (steps per min)	52	696	1.26 (1.88; −2.43 to 4.95)	.50	0.312

[a]DID: difference in differences. DID indicates the group × phase interaction.

[c]Acal: activity-related calorie expenditure.

[d]MET: metabolic equivalent of task.

PPS Analysis

The PPS sensitivity analysis included 44 participants who provided 595 daily observations. This analysis revealed the same directional pattern as observed with the primary model but with wider CIs. The DID estimate for step length was 1.95 cm (*P*=.13), whereas that for walking speed was 0.04 m/s (*P*=.14) and that for cadence was 1.03 steps per minute (*P*=.62). The effects of the intervention on daily steps and active energy expenditure remained null in the PPS analysis (β=–286.25 steps per day and *P*=.62; β=–8.88 kcal per day and *P*=.72). The effects on daily distance and accumulated 3 or more MET activities were also null (β=–0.01 km per day and *P*=.98; β=–0.09 MET hours per day and *P*=.80; Table 3).

Trajectory of Daily-Life Walking Outcomes

Figure 2 shows descriptive day-by-day trajectories for daily steps (Figure 2A) and daily walking speed (Figure 2B) from days 2 to 98 aligned to each participant's day 1 (first recorded date). The daily walking speed trajectory showed a modest separation between the groups, emerging around the midintervention phase and persisting up to the end of follow-up, whereas the daily step trajectory did not show a similarly clear pattern. According to participation logs, the median program started on day 27 (IQR 26 - 29) in the control group and day 29 (IQR 28 - 30) in the intervention group. These figures are descriptive, and formal inference is provided by the mixed-effects models.

Adverse Events

One adverse event was reported in the control group, and no adverse events were reported in the intervention group.

Discussion

Walking parameters, particularly walking speed and step length, are well-established indicators of adverse health outcomes such as mortality and disability [1,28]. There is accumulating evidence suggesting that these daily-life gait characteristics are also informative for health risk, including the risk of falls and frailty [20,22,29].

Principal Findings

In this study, we examined whether a hybrid multicomponent training program influenced daily-life walking. In mixed-effects analyses using all available daily observations, the clearest effect of the intervention was observed on step length, whereas cadence showed no clear effect of the intervention and walking speed showed a smaller effect, with borderline statistical significance. Although the step length estimate is of a moderate effect size (Hedges *g* of approximately 0.49), the small sample size of this secondary analysis yielded a wide CI; therefore, whether the change reaches a minimal clinically important difference remains uncertain. Activity volume outcomes, including daily steps and active energy expenditure, were not clearly altered by the training program. Overall, the effect of the intervention was more consistently observed on gait quality than on activity volume.

In this study, the most consistent effect of the intervention was observed on step length, whereas changes in cadence were small and imprecise, particularly in the PPS analysis. This pattern suggests that any intervention-related change in daily-life walking quality may have been driven more by step length than by cadence. A previous study demonstrated that daily-life cadence was associated with ambient temperature and may be modulated by autonomic responses [30]. Such influences may attenuate intervention-related changes in cadence compared with more mechanically determined gait parameters such as step length [31]. Although these findings remain exploratory, a between-group difference in step length of approximately 2 cm is not negligible from a gait quality perspective in older adults.

In contrast to the consistent improvements observed in gait characteristics, effects on activity volume outcomes were less clear. The multicomponent program did not incorporate components designed to promote behavior change, such as goal setting, self-monitoring, or structured activity coaching. Moreover, the intervention was intentionally designed as a scalable, video-guided program delivered without continuous specialist supervision. Although this format supports scalability, it may make it more difficult to embed individualized, multifaceted behavior change support. Prior evidence similarly indicates that interventions focused on symptoms and physical function do not necessarily lead to increases in objectively measured physical activity [32]. When increasing activity volume is an explicit goal, exercise-based interventions may need to incorporate behavior change techniques [33,34].

The descriptive walking speed trajectory (Figure 2B) was presented to provide an intuitive representation of how intergroup differences may have evolved over time. According to the participation logs, program initiation clustered around days 26 to 30 (control group: median day 27, IQR 26‐29; intervention group: median day 29, IQR 28‐30), and the speed trajectory suggested modest visual separation between the groups from approximately day 40. This timing corresponds to approximately 2 weeks after initiation and is broadly consistent with that in exercise-based randomized trials for knee osteoarthritis, in which intergroup differences could be detected within approximately 2 weeks for pain and functional outcomes and within approximately 3 weeks for changes in walking speed [35,36]. Notably, the trajectory plot suggested a maintenance pattern in the intervention group rather than a marked improvement. The observed intergroup difference may therefore reflect prevention in the intervention group of the decline observed in the control group.

Limitations

We observed some inconsistencies in statistical significance between the results of mixed-effects analyses using all available daily observations and those of the PPS sensitivity analyses for certain outcomes. Across multiple activity-related measures, including steps per day, daily walking distance, active energy expenditure, and MET-based indexes, no consistent intervention effect was observed. In the PPS set, the smaller sample size reduced statistical precision and widened CIs, making statistical significance less likely. However, the overall interpretation was consistent across analytic sets. Model residuals departed from normality for several outcomes, and in a distribution-robust sensitivity check, the one nominally significant outcome (step length) was no longer statistically significant; therefore, the findings are interpreted as suggestive.

This study has some limitations despite its strengths, such as objective, automatically derived free-living gait outcomes and comparison against an active control condition. The participants were recruited from a single setting and were required to attend sessions, which may limit generalizability. Additionally, this was a secondary analysis of activity monitor–derived outcomes, and the parent trial sample size was determined for symptom outcomes rather than specifically for the present free-living gait outcomes; accordingly, precision may have been limited for modest between-group differences. The cohort was clinically heterogeneous in baseline symptom burden; combined with the modest sample size of this secondary analysis, this may have increased between-participant variability and limited the precision of the between-group estimates. Participants who refused to wear the device or withdrew before outcome collection contributed no activity monitor data within the planned pre- and postintervention windows and, therefore, did not contribute data to the mixed-effects analyses of device-derived outcomes. The postwindow anchor was the last monitoring day rather than a fixed postcompletion assessment date, so the exact interval between intervention completion and the measured window differed between participants. The per-protocol definition may have also influenced PPS estimates, and the PPS findings should be interpreted as sensitivity analyses. Finally, we did not directly measure key mediators of

XSL•FO
RenderX

change (eg, pain trajectories), and longer follow-up will be needed to assess the durability and downstream clinical outcomes.

Practical Implications

This study has practical implications for scalable pain management services. Many exercise-based programs for knee and low back pain demonstrate benefits under professional supervision, yet widespread implementation is constrained by time and workforce. The current hybrid model of video-guided sessions with staff assistance may offer a feasible option that can be delivered at scale while potentially being consistently associated with a signal for daily-life gait quality. From a clinical perspective, the gait outcomes are clinically meaningful because gait speed is a robust indicator of overall health and ability to function and predicts adverse outcomes such as disability and mortality in older adults [28,37-39]. In the present study, the speed signal was modest and imprecise, whereas the step length signal was more consistent. Hence, clinical interpretation may focus primarily on gait quality rather than on activity volume while recognizing that even modest changes in physical performance measures may be clinically meaningful in older adults [40].

Conclusions

A 12-week hybrid multicomponent program combining video-guided exercise with staff assistance may be associated with a suggestive signal for better daily-life walking quality, with the clearest effect observed for step length in older adults with knee and low back pain. However, given the attenuation in sensitivity analyses and the multiplicity of outcomes assessed, these findings should be regarded as exploratory.

Acknowledgments

The authors appreciate the staff who assisted with this study and the study participants. During the preparation and revision of this manuscript, the authors used ChatGPT (OpenAI) to assist with rephrasing, English translation, proofreading, and language polishing of text originally written by the authors. All AI-assisted revisions were critically reviewed and edited by the authors, who take full responsibility for the final content of the manuscript.

Funding

This study was supported by Curves Japan through providing funding and the intervention venue and delivering the intervention services. The funder had no role in the data analysis, interpretation of the findings, or preparation of the manuscript.

Data Availability

The datasets analyzed during the current study are not publicly available due to ethical restrictions and participant confidentiality concerns but are available from the corresponding author to qualified researchers on reasonable request.

Abstract

Background: Community exergaming may help older adults remain physically active by combining movement, enjoyment, and social interaction, but less is known about whether observed changes persist after supervised delivery ends in real-world community settings.

Objective: This study evaluated immediate and maintenance-related outcomes of the International Singapore Intergenerational National Games, a community-delivered exergaming program for older adults in Singapore. We examined positive mental health, intrinsic motivation, habit strength, physical activity, and exploratory implementation determinants aligned with the capability, opportunity, and motivation–behavior (COM-B) framework.

Methods: We conducted a multi-wave observational evaluation from October 2025 to January 2026 among 280 older adults recruited from 14 senior activity centers or active aging centers in Singapore. Assessments were conducted at baseline (T0), immediately after an 8-week supervised training phase (T1), after a 4-week unsupervised free-play phase (T2), and at a later follow-up for selected measures in 6 centers (T3). Immediate within-person changes were examined using 2-tailed paired *t* tests. Maintenance-related trajectories were examined using adjusted linear mixed-effects models. Exploratory analyses examined whether COM-B–aligned capability, opportunity, and motivation composites were associated with physical activity trajectories.

Results: Participants had a mean age of 72.54 (SD 6.15) years, and 77.1% (216/280) were female. From T0 to T1, mean positive mental health increased from 55.19 (SD 9.79) to 57.59 (SD 8.70; Cohen *dz*=0.28; *P*<.001), mean intrinsic motivation increased from 5.94 (SD 1.00) to 6.29 (SD 0.81; Cohen *dz*=0.40; *P*<.001), and mean habit strength increased from 3.34 (SD 1.11) to 3.81 (SD 0.84; Cohen *dz*=0.42; *P*<.001). In adjusted mixed models, habit strength remained higher at T2 than at baseline (β=0.362, 95% CI .113-.611; *P*=.005), and intrinsic motivation remained higher at T2 (β=0.397, 95% CI .156-.638; *P*=.001) and T3 (β=0.305, 95% CI .009-.601; *P*=.04). Positive mental health was higher immediately after supervised training (β=4.140, 95% CI 2.169-6.111; *P*<.001) and at T2 (β=7.390, 95% CI 5.370-9.410; *P*<.001) than at baseline. Among the COM-B domains, only opportunity was associated with greater immediate posttraining physical activity improvement (time × opportunity interaction β=26.464, 95% CI 3.191-49.737; *P*=.03), with no evidence of a sustained interaction at T2.

Conclusions: In this observational evaluation, positive mental health, intrinsic motivation, and habit strength were higher at T2 than at baseline among respondents with available follow-up data, and intrinsic motivation was also higher at the selected-center T3 follow-up. Because this study lacked a control group and attrition increased over time, these findings represent observed longitudinal trajectories rather than causal evidence of program effectiveness. Opportunity-related supports such as access, reminders, routines, staff facilitation, and peer participation may be useful when community exergaming transitions from supervised delivery to reduced-intensity free play, although this interpretation remains exploratory.

Introduction

Community and group-based exergaming have attracted growing interest as a potentially scalable strategy for promoting later-life activity by combining movement, enjoyment, and social interaction. However, less is known about whether implementation-relevant gains persist once structured supervision is withdrawn in routine community settings. Across older adult studies, the most consistent benefits have been observed for balance and mobility, although effect sizes vary and intervention designs remain heterogeneous [1-5]. Cognitive and psychosocial outcomes are more mixed: reviews suggest possible benefits for mood, cognition, and health-related quality of life, but they also emphasize variability in delivery platforms, dose, comparator conditions, and measurement [2,6-8]. There is recent evidence likewise suggesting that different exergame emphases may yield different cognitive vs balance gains, underscoring the importance of intervention design [9].

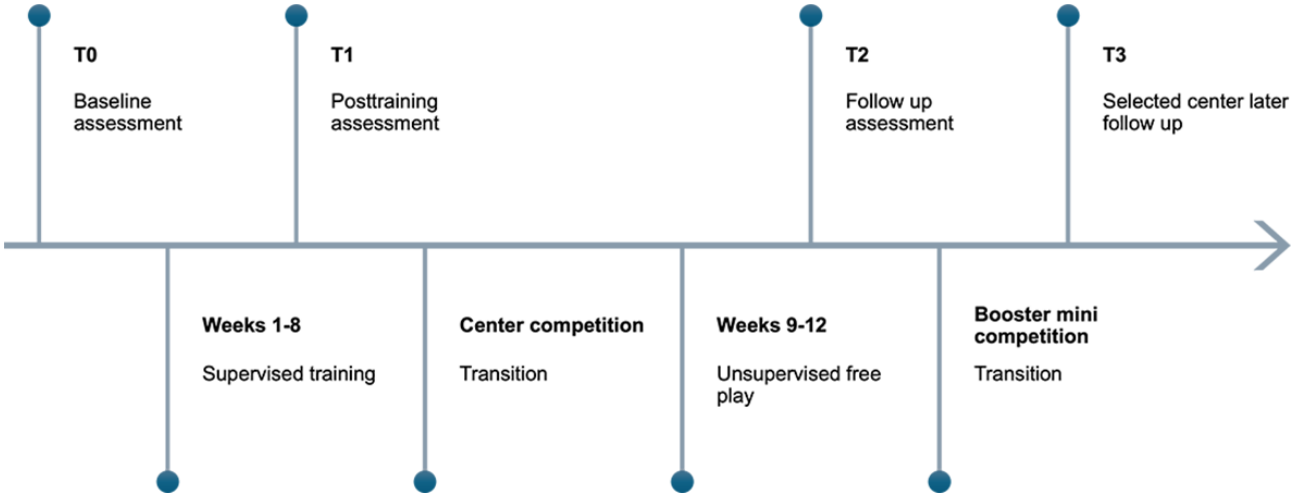
Social and implementation questions remain especially important for community translation. Social outcomes are still measured inconsistently, yet there is available evidence suggesting that socially interactive or multiple-player exergaming formats may enhance loneliness-related and depressive outcomes more than solitary modes [10,11]. At the same time, follow-up beyond the immediate posttest remains limited, leaving uncertainty about what happens when staff prompting and structured supervision are reduced [2,5,12]. Qualitative and mixed methods studies further indicate that enjoyable gameplay alone is insufficient for implementation; familiarization, clear instructions, accessible design, confidence building, and social support all shape uptake and continued use [12-14].

The capability, opportunity, and motivation–behavior (COM-B) model provides a useful framework for examining these questions because it conceptualizes behavior as arising from capability, opportunity, and motivation [15]. Within this framework, intrinsic motivation and habit strength can be understood as motivational processes that may support behavioral maintenance, whereas opportunity reflects the social and environmental conditions that make continued activity possible after supervision is reduced. Self-determination theory further suggests that autonomy, competence, and relatedness-supportive delivery practices can foster more self-sustaining forms of motivation; recent consensus work has translated these principles into observable motivational behaviors that may be useful for community program delivery [16]. In a pragmatic community program, opportunity-related conditions such as access, reminders, peer presence, and light-touch support may be especially relevant once formal supervision decreases. The present study evaluated the International Singapore Intergenerational National Games (I-SING), a real-world community exergaming program delivered through senior activity centers and active aging centers in Singapore. The evaluation captured a supervised training phase, a deliberately designed 4-week unsupervised free-play phase, and later follow-up for selected measures.

Guided by the COM-B framework, we examined immediate and maintained changes in positive mental health, intrinsic motivation, habit strength, and physical activity together with descriptive feedback on program acceptability and barriers to continued participation. Because this study used an observational pretest-posttest design, the analyses were intended to describe trajectories and implementation-relevant associations rather than establish causal effectiveness.

This study tested 3 hypotheses:

- Hypothesis 1—positive mental health, intrinsic motivation, and habit strength would improve immediately after the supervised training phase.
- Hypothesis 2—intrinsic motivation and habit strength would remain higher during reduced-intensity follow-up than at baseline, whereas gains in positive mental health were expected to be less stable after structured social contact decreased.
- Hypothesis 3—higher COM-B–aligned capability, opportunity, and motivation scores would be associated with more favorable physical activity trajectories, with opportunity expected to be particularly relevant after supervision was reduced.



Methods

Study Design

We conducted a multi-wave observational evaluation of the I-SING, a community-delivered intergenerational exergaming program for older adults in Singapore. Assessments were conducted before supervised training (T0), immediately after supervised training (T1), after a 4-week unsupervised free-play period (T2), and at a later follow-up for selected measures (T3). The design was pragmatic and did not include a control or comparison group. Therefore, this study could identify within-person changes and implementation-relevant associations, but it could not rule out secular trends, regression to the mean, center-level contextual effects, or other unmeasured confounders. The study design and assessment timeline are shown in Figure 1.

XSL•FO
RenderX

Figure 1. Study design and assessment timeline. T3 was conducted 1 week after the booster mini competition in 6 selected centers.

Participants and Recruitment

Older adults were recruited from October 2025 to January 2026 through 14 participating senior activity centers and active aging centers using center-based outreach and posters. Eligibility followed the approved study protocol: participants were required to be 60 years of age or older, community ambulant, able to perform light physical activity, and free of a physical impairment that would preclude participation. Serious mental disorders were an exclusion criterion. Of 280 participants with baseline data, 2 (0.7%) withdrew at the program start, leaving 278 (99.3%) who entered the supervised phase. At the end of the 8-week supervised intervention, 243 participants completed the program; 242 (99.6%) provided analyzable posttraining (T1) survey data. After the 4-week unsupervised free-play phase, 230 participants contributed T2 data. Later follow-up (T3) was conducted only in 6 selected centers, where 120 participants were eligible for follow-up and 88 (73.3%) completed the T3 survey. Attrition analyses comparing baseline characteristics between completers and noncompleters at T1, T2, and T3 can be found in Tables S1 to S3 in Multimedia Appendix 1. At T1, completers were more likely than noncompleters to have previously played exergames and participated in I-SING. No clear baseline differences were observed between T2 completers and noncompleters. Among participants selected for T3 follow-up, completers differed from noncompleters in community center attendance frequency and were more likely to have previously played exergames and participated in I-SING. Other baseline demographic characteristics were generally comparable between completers and noncompleters across the assessment points.

Program Procedures

The supervised phase consisted of 8 weekly sessions delivered over 8 weeks. After T1, a center competition was held, followed by a 4-week unsupervised free-play phase intended to observe naturalistic engagement under reduced staff prompting. A booster mini competition was introduced only after T2 data collection to reduce anticipation effects. Surveys required approximately 45 to 60 minutes at each wave.

Outcome Measures

The focal outcomes for the present analyses were positive mental health, intrinsic motivation, and habit strength. Physical activity and COM-B–aligned implementation drivers were examined as exploratory, implementation-oriented outcomes. Detailed descriptions of additional measures collected for broader program evaluation, including healthy lifestyle, self-reported health, and health ownership, can be found in Multimedia Appendix 1.

Ethical Considerations

This study was approved by the Nanyang Technological University Institutional Review Board (IRB-2023-321), including protocol amendments covering revised training formats and the unsupervised free-play period. All participants provided written informed consent before enrollment. Survey data were collected and analyzed in deidentified form to protect participant privacy and confidentiality. Participants received shopping vouchers as compensation for participation.

Demographic Characteristics

A 9-item questionnaire assessed employment status, living arrangement, educational level, marital status, household size, perceived adequacy of money for daily expenses, frequency of community center visits, prior exergaming experience, and prior participation in I-SING. These variables were used to characterize the sample and, where relevant, as covariates.

Positive Mental Health

Positive mental health was measured using the 14-item Mental Health Continuum–Short Form (MHC-SF), which assesses emotional, social, and psychological well-being [17]. Participants rated how often they had experienced each feeling during the previous month on a 6-point scale ranging from 0 (never) to 5 (every day). The 14 harmonized item scores were summed to produce total scores ranging from 0 to 70, with higher scores indicating better positive mental health.

Motivation for Exergaming

Motivation for exergaming was assessed using an adapted version of the Motives for Physical Activity Measure–Revised (MPAM-R) [18]. Adaptation consisted of wording the original physical activity items to refer specifically to exergaming participation; no substantive changes were made to the response scale or intended construct. Items were rated on a 7-point scale ranging from 1 (not at all) to 7 (describes exactly). The present

XSL•FO
RenderX

analyses focused on the intrinsic motivation score, with higher values indicating stronger intrinsically oriented motivation to engage in exergaming.

Habit Strength

Habit strength was assessed using the 12-item Self-Report Habit Index (SRHI) [19]. Items were rated on a 5-point scale ranging from 1 (strongly disagree) to 5 (strongly agree). Item responses were averaged, with higher scores indicating stronger habit strength for the target behavior.

Physical Activity

Physical activity was assessed using the Physical Activity Scale for the Elderly (PASE), a measure of leisure-time, household, and work-related activity in older adults [20]. Scores were calculated using the recommended weighted scoring procedure, with higher scores indicating greater physical activity. Because the PASE is a weighted composite of distinct physical activity domains rather than a unidimensional scale, internal consistency was not calculated.

Program Experience and Feedback

At T3, participants from selected centers completed program feedback items on game preferences, enjoyment, recommendations, and suggestions for improvement. These responses were summarized descriptively to characterize program acceptability and practical implications for community delivery.

Measurement Reliability

At T1, internal consistency was good for the 14-item MHC-SF (Cronbach α=0.89; n=242), the 14-item adapted MPAM-R intrinsic motivation score (Cronbach α=0.87; complete n=218), and the 12-item SRHI (Cronbach α=0.90; complete n=201). Designated missing value codes and values outside the prespecified response ranges were treated as missing before the coefficients were calculated. Internal consistency was not estimated for the PASE because its weighted total combines conceptually distinct activity domains rather than parallel items measuring a unidimensional construct.

Operationalization of COM-B–Aligned Drivers

To explore implementation-relevant correlates of physical activity maintenance, we constructed 3 theory-informed composite indexes aligned with the COM-B domains of capability, opportunity, and motivation. These composites were pragmatic summary indicators for exploratory analysis and should not be interpreted as validated latent COM-B scales. Capability comprised health literacy, self-efficacy, information seeking, and health citizenship or control; opportunity comprised supportive accountability, perceived social support, responsibility and social contract, community actor, and collective efficacy; and motivation comprised healthy lifestyle, positive mental health, intrinsic and extrinsic motivation, habit strength, and self-reported health. Because the motivation composite included constructs that overlapped with the primary outcomes, we did not interpret this domain as an independent predictor of those same outcomes. Accordingly, the COM-B analyses were limited to physical activity trajectories and interpreted cautiously to minimize the risk of conceptual circularity.

Because this study focused on maintenance after supervised training, posttraining values were used preferentially to represent participants' readiness for the reduced-intensity phase; baseline values were used only when posttraining values were unavailable. Component measures were standardized before aggregation, and higher composite scores indicated relatively greater capability, opportunity, or motivation. Full details on composite construction, weighting, equations, missing data handling, and a recommended sensitivity analysis excluding overlapping motivation indicators are provided in Multimedia Appendix 1.

Statistical Analysis

Baseline characteristics were summarized using means and SDs for continuous variables and frequencies and percentages for categorical variables. The primary outcomes were positive mental health, intrinsic motivation, and habit strength. Immediate within-person change from T0 to T1 was examined using paired *t* tests based on complete pairs and reported as Cohen *dz* with 95% CIs. Maintenance across waves was examined using linear mixed-effects models with time as a categorical fixed effect and participant as a random intercept, adjusted for age, sex, and cohort and year. These covariates were selected a priori because age and sex are commonly associated with physical activity and psychosocial outcomes in older adults and cohort and year captured implementation differences across program cohorts. Analyses of PASE trajectories and COM-B driver interactions were prespecified as exploratory implementation-oriented analyses. All analyses used available data and were conducted in R (version 4.5.1; R Foundation for Statistical Computing). No imputation was performed; therefore, findings assume that missingness was adequately handled by the available-data mixed-model framework conditional on observed covariates and should be interpreted alongside attrition patterns.

Results

Sample and Baseline Characteristics

At baseline, the sample had a mean age of 72.54 (SD 6.15) years, 77.1% (216/280) of the participants were female, and 92.1% (258/280) identified as Chinese. Most participants were not working (244/277, 88.1%), and many reported frequent visits to community centers. Prior exergaming exposure was present but not dominant: 41.4% (115/278) of the participants had played exergames, and 21.9% (61/278) had participated in I-SING previously. Baseline sample characteristics are shown in Table 1. Participant flow is reported in accordance with STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidance and shown in Figure 2.

[a]I-SING: International Singapore Intergenerational National Games.

XSL•FO
RenderX

Figure 2. STROBE (Strengthening the Reporting of Observational Studies in Epidemiology)–style participant flow diagram. T0: baseline; T1: after an 8-week supervised training phase; T2: after a 4-week unsupervised free-play phase; T3: at a later follow-up for selected measures in 6 centers.

Immediate Program Effects

From T0 to T1, participants showed within-person increases in the 3 prespecified proximal outcomes. Mean positive mental health increased from 55.19 (SD 9.79) at T0 to 57.59 (SD 8.70) at T1 among 240 complete pairs (Cohen *dz*=0.279, 95% CI 0.149-0.407; *P*<.001). Mean intrinsic motivation increased from 5.94 (SD 1.00) to 6.29 (SD 0.81) among 166 paired observations (Cohen *dz*=0.398, 95% CI 0.239-0.555; *P*<.001). Mean habit strength increased from 3.34 (SD 1.11) to 3.81 (SD 0.84) among 143 paired observations (Cohen *dz*=0.423, 95% CI 0.252-0.594; *P*<.001). These results support hypothesis 1 but should be interpreted as changes observed after program participation rather than controlled intervention effects. Pair-specific sample sizes for the primary outcomes are reported in Table S4 in Multimedia Appendix 1.

Exploratory paired analyses of additional psychosocial variables are summarized in Table S5 in Multimedia Appendix 1. Briefly, small significant increases were observed for extrinsic motivation (*P*=.009) and social responsibility (*P*=.009), whereas collective efficacy decreased slightly (*P*=.03); no reliable immediate change was detected for self-efficacy (*P*=.24), supportive accountability (*P*=.31), perceived social support (*P*=.26), information seeking (*P*=.63), or health literacy (*P*=.73).

Maintenance Under Reduced Intensity

Hypothesis 2 was partially supported. Habit strength was higher immediately after supervised training (β=0.291, 95% CI .047-.535; *P*=.02) and after the free-play phase at T2 (β=0.362, 95% CI .113-.611; *P*=.005) than at baseline. Intrinsic motivation was higher at T2 (β=0.397, 95% CI .156-.638; *P*=.001) and at the selected-center T3 follow-up (β=0.305, 95% CI .009-.601; *P*=.04) than at baseline. Contrary to the expectation that positive mental health gains would be less stable, positive mental health was higher both immediately after supervised training (β=4.140, 95% CI 2.169-6.111; *P*<.001) and at T2 (β=7.390, 95% CI 5.370-9.410; *P*<.001) than at baseline. The paired T0-to-T2 change in positive mental health was moderate (n=228; Cohen *dz*=0.520, 95% CI 0.382-0.658; *P*<.001).

These findings indicate that positive mental health, intrinsic motivation, and habit strength were all higher at T2 than at baseline among respondents with available follow-up data.

XSL•FO
RenderX

Nevertheless, because this study lacked a control group and relied on available observations, the changes cannot be attributed causally to I-SING. Secular changes, contextual influences, and selective retention remain possible alternative explanations (Table 2).

Table . Primary and maintenance outcomes across study waves[a].

Outcome and time point	Participants, n	Score, mean (SD)	Contrast vs baseline, β (95% CI)	*P* value	Paired effect size, Cohen *dz*
Habit strength (range 1-5)					
Before	278	3.319 (1.103)	Reference	—[b]	—
After	242	3.729 (0.836)	0.291 (0.047 to 0.535)	.02	0.423
T2[c]	230	3.729 (0.817)	0.362 (.113 to 0.611)	.005	0.382
Intrinsic motivation (range 1-7)					
Before	278	5.945 (0.982)	Reference	—	—
After	242	6.305 (0.764)	0.184 (–0.054 to 0.421)	.13	0.398
T2	230	6.403 (0.683)	0.397 (0.156 to 0.638)	.001	0.512
T3[d]	88	6.349 (0.988)	0.305 (0.009 to 0.601)	.04	0.291
Positive mental health (MHC-SF[e] total; 0-70)					
Before	278	55.076 (9.726)	Reference	—	—
After	242	57.674 (8.712)	4.140 (2.169 to 6.111)	<.001	0.279
T2	230	60.622 (8.131)	7.390 (5.370 to 9.410)	<.001	0.520

[a]Mixed-effects models included time as a categorical fixed effect and participant as a random intercept and were adjusted for age, sex, and program cohort and year. Positive β values indicate scores higher than baseline. The n values represent the number of available observations at each wave. Paired effect sizes were calculated using complete pairs; pair-specific sample sizes are reported in Table S4 in Multimedia Appendix 1. For the Mental Health Continuum–Short Form, the T0-to-T1 effect size was based on 240 complete pairs, and the T0-to-T2 effect size was based on 228 complete pairs.

[b]Not applicable because baseline was the reference category; therefore, no P value or paired effect size was calculated.

[c]T2: after a 4-week unsupervised free-play phase.

[d]T3: at a later follow-up for selected measures in 6 centers.

[e]MHC-SF: Mental Health Continuum–Short Form.

Taken together, the adjusted models indicated that positive mental health, intrinsic motivation, and habit strength were higher at T2 than at baseline among respondents with available data. Intrinsic motivation was also higher at the selected-center T3 follow-up than at baseline. These results describe observed longitudinal trajectories and should not be interpreted as evidence that the reduced-intensity phase caused the outcomes to be maintained.

COM-B Drivers and Physical Activity Maintenance Over Time

Hypothesis 3 examined whether higher COM-B–aligned capability, opportunity, and motivation were associated with differences in physical activity trajectories across baseline, immediately after training, and the T2 follow-up (Table 3). In mixed-effects models, only opportunity significantly moderated immediate change in physical activity after training (time × opportunity interaction β=26.464, 95% CI 3.191-49.737; *P*=.03). No significant time interactions were observed for capability or motivation, and no COM-B domain significantly moderated T2 physical activity change. In separate end point models, baseline PASE strongly predicted both posttraining and follow-up PASE scores, whereas opportunity showed only borderline evidence of association with posttraining PASE scores (detailed end point regression results can be found in Table S6 in Multimedia Appendix 1). Given the number of exploratory interactions tested, this result should be interpreted as a preliminary hypothesis-generating signal rather than definitive evidence that opportunity is more important than other COM-B domains.

XSL•FO
RenderX

Table . Associations between capability, opportunity, and motivation–behavior (COM-B) drivers and physical activity maintenance over time. Positive estimates indicate stronger increases in Physical Activity Scale for the Elderly among participants with higher standardized driver scores.

COM-B driver and interaction term	Regression coefficient, β (95% CI)	*P* value	Interpretation
Capability			
T1[a] × capability	−9.332 (−32.331 to 13.666)	.42	No evidence of interaction
T2[b] × capability	9.252 (–14.230 to 32.735)	.44	No evidence of interaction
Opportunity			
T1 × opportunity	26.464 (3.191 to 49.737)	.03	Higher opportunity associated with greater immediate increase in PASE[c]
T2 × opportunity	0.164 (–23.606 to 23.934)	.99	No evidence of interaction
Motivation			
T1 × motivation	10.015 (–10.159 to 30.190)	.33	No evidence of interaction
T2 × motivation	−6.623 (–27.145 to 13.899)	.52	No evidence of interaction

[a]T1: immediately after an 8-week supervised training phase.

[b]T2: after a 4-week unsupervised free-play phase.

[c]PASE: Positive estimates indicate greater increases in PASE among participants with higher standardized driver scores.

The COM-B domains were operationalized as follows: capability comprised health literacy, self-efficacy, information seeking, and control; opportunity comprised supportive accountability, perceived social support, responsibility and social contract, community actor, and collective efficacy; and motivation comprised healthy lifestyle, positive mental health, intrinsic and extrinsic motivation, habit, and self-reported health. The standardized COM-B driver scores were centered around 0, with means close to 0 and SDs ranging from 0.605 to 0.638, indicating comparable scaling across the 3 domains. These composites were exploratory and theory informed, and their results should not be interpreted as validated COM-B measurement scores.

Mixed-effects models assessed whether capability, opportunity, and motivation moderated physical activity trajectories from baseline to the posttraining and follow-up periods. Mean PASE scores increased modestly from baseline (mean 143.71, SD 66.42) to the posttraining time point (mean 147.81, SD 66.91) and declined at T2 (mean 137.02, SD 58.53). Among the 3 COM-B domains, only opportunity significantly moderated immediate posttraining change in physical activity. In separate end point models, baseline physical activity strongly predicted both posttraining and follow-up PASE scores, whereas opportunity showed only borderline evidence of association with posttraining PASE scores.

Game Feedback From Selected Centers at T3

Because T3 feedback was available only for selected centers, these findings are presented descriptively. Overall, the exergaming component appeared to be well accepted. Apple Frenzy emerged as the most consistently preferred game and was commonly described as easy to play, enjoyable, relaxing, colorful, and easy to score. Fishing Frenzy was also frequently identified as a favorite because it was perceived as fun, active, and similar to exercise. Punch Punch and Whack-a-Mole were also popular, particularly among participants who valued excitement, reflex training, or challenges. In contrast, more cognitively demanding or faster-paced games such as Chinatown Rush and Red Light Rat Race appeared more polarizing. Participants also most often described Cat Stack, Don’t Forget to Wipe, and Ice Breaker negatively, typically because they were perceived as too difficult, tiring, frustrating, or hard to control. Detailed game-level results are provided in Table S7 in Multimedia Appendix 1.

Open-ended comments suggested that continued engagement during free play depended not only on game enjoyment but also on center-level opportunity conditions, including reminders, scheduling, staff support, and available space. This descriptive pattern was consistent with the quantitative finding that opportunity was the only COM-B domain associated with stronger immediate posttraining physical activity improvement.

Notably, participants often described Fishing Frenzy as enjoyable because it involved substantial movement and “helps me exercise.” This complements the supplementary functional movement mapping, within which Fishing Frenzy is characterized as a repeated sit-to-stand task with likely lower-limb strengthening and balance-related benefits. Thus, participant feedback supports the view that games with clear, functional, exercise-like movement demands may be especially acceptable in community exergaming for older adults.

Discussion

Principal Findings

This multi-wave observational evaluation examined whether changes in psychosocial and behavioral outcomes persisted after a community exergaming program transitioned from supervised training to reduced-intensity free play. Positive mental health, intrinsic motivation, and habit strength increased immediately after supervised training and were higher at T2 than at baseline among respondents with available data; intrinsic motivation was also higher at the selected-center T3 follow-up than at baseline. Opportunity was the only COM-B domain associated

XSL•FO
RenderX

with greater immediate posttraining change in physical activity, and no COM-B domain moderated T2 change. These findings represent observed longitudinal trajectories and exploratory associations rather than causal program effects.

The immediate pattern is broadly consistent with earlier exergaming research. Reviews have repeatedly found the strongest and most consistent benefits in movement-related outcomes such as balance and mobility, whereas psychosocial effects are more heterogeneous across studies and measures [2,3,5,6]. The present study contributes something different: it evaluated a large, community-delivered program operating through routine service infrastructure in Singapore rather than a tightly controlled efficacy trial. This makes the findings especially relevant for implementation decisions in community aging services.

The maintenance-related findings extended beyond motivation and habit [13,14,18]. Positive mental health was also higher at T2 than at baseline, contrary to the expectation that mental health gains would be less stable after structured social contact decreased. The sustained differences in positive mental health, intrinsic motivation, and habit strength suggest that favorable outcomes were observed beyond the supervised phase among participants who remained in follow-up. However, attrition, the relatively short follow-up period, and the absence of direct free-play use data limit conclusions about maintenance in the full cohort and about whether these psychosocial and habit-related scores translated into continued exergaming participation.

Positive mental health was higher immediately after supervised training and at T2 than at baseline. This pattern suggests that the observed improvement was not confined to the supervised phase. However, because this study lacked a control group and the T2 analysis relied on available follow-up data, the higher score cannot be attributed causally to I-SING. Secular changes, center-level context, survey administration conditions, and selective retention may also have contributed to the observed trajectory.

The COM-B results provide a cautious implementation signal rather than a definitive mechanism test. Of the 3 COM-B domains, only opportunity was associated with stronger immediate posttraining physical activity change. In COM-B terms, opportunity refers to the environmental and social conditions that enable behavior, including access, social support, cues, and a facilitating context [15]. This interpretation is plausible in community exergaming because reminders, peer presence, accessible scheduling, and light-touch staff support may help older adults translate interest into actual participation. However, the opportunity result should be considered hypothesis generating because multiple interactions were tested, the composites were not validated COM-B scales, and center-level context may have contributed to the observed association.

The descriptive game feedback supports that same conclusion. Participants preferred games that combined intuitive movement, moderate pace, clear goals, and a rewarding sense of exercise. Fishing Frenzy and Apple Frenzy appeared to work well because they were both accessible and meaningfully active, with Fishing Frenzy often described as helping participants exercise. In contrast, games perceived as confusing, overly fast, poorly tracked, or physically unrewarding were less acceptable. Importantly, free-play barriers were often logistical rather than motivational, reinforcing the inference that access, reminders, scheduling, and space matter as much as game enjoyment once supervision recedes [13,15].

Several limitations should be acknowledged. First, the observational pretest-posttest design lacked a control group, limiting causal inference and preventing attribution of the observed changes to I-SING alone. Second, analyses used available observations, and attrition reduced the sample for paired comparisons and later follow-up. Selective retention of participants who were more engaged, healthier, or more familiar with exergaming may have contributed to the apparent maintenance-related trajectories. Third, T3 was restricted to selected centers, limiting the generalizability of those findings. Fourth, no automated logs or equivalent individual-level records of free-play exposure were available; consequently, higher motivation and habit scores cannot be assumed to represent continued exergaming participation. Fifth, the PASE was self-reported. Sixth, the COM-B composites were theory-informed pragmatic indexes rather than validated measures, and the motivation composite contained constructs that overlapped conceptually with the primary outcomes. Finally, no dedicated validated social outcome battery was administered, so conclusions regarding loneliness, social connectedness, or social participation cannot be drawn. Future studies should include controlled comparisons, direct measures of program exposure and adherence, validated social health outcomes, and sensitivity analyses addressing missing data and center-level clustering.

Conclusions

In this multi-wave observational evaluation of community exergaming for older adults, positive mental health, intrinsic motivation, and habit strength were higher at T2 than at baseline among respondents with available follow-up data, and intrinsic motivation was also higher at the selected-center T3 follow-up. These findings suggest maintenance-related signals across both psychosocial and behavioral outcomes, but the uncontrolled design, attrition, selected-center follow-up, and absence of direct free-play exposure data preclude causal conclusions. Opportunity-related supports such as access, reminders, scheduling, staff facilitation, and peer participation may be useful when programs transition from supervised sessions to reduced-intensity free play, although this interpretation remains exploratory. Future controlled studies with consistent cross-wave scoring, validated social outcomes, and direct tracking of program exposure are needed to clarify maintenance pathways.

Acknowledgments

The authors sincerely thank all older adult participants and the partnering active aging centers involved in the International Singapore Intergenerational National Games program. They are particularly grateful to the senior activity center and active aging center management teams and staff for their generous support in organizing sessions, coordinating participants, and facilitating implementation across sites. The authors also thank the student interns from Nanyang Technological University for their assistance with program delivery, logistics, and administrative tasks. Finally, they acknowledge the support of the Ageing Research Institute for Society and Education, Nanyang Technological University, for this study. The authors used ChatGPT (OpenAI) to assist with language editing and improving the clarity of the manuscript. It was not used to generate study data or perform the statistical analyses. All AI-assisted content was critically reviewed and verified by the authors. The authors take full responsibility for the accuracy, integrity, and final content of the manuscript.

Funding

This work was supported by the Ageing Research Institute for Society and Education, Nanyang Technological University. The funder had no role in the study design; data collection, analysis, and interpretation; manuscript preparation; or decision to submit the manuscript for publication.

Data Availability

The datasets generated and analyzed during this study are not publicly available because they contain potentially identifiable participant information and are subject to institutional data governance requirements of the Ageing Research Institute for Society and Education, Nanyang Technological University. Deidentified data may be made available from the corresponding author on reasonable request, subject to institutional review and permission from the data custodian.

Authors' Contributions

YL conceived the study, led the analysis, and drafted the manuscript. BXC, HYK, and QNTN contributed to program implementation and data acquisition. JJ, KMWYT, and SQAL contributed to data analysis and manuscript revision. YLT contributed to study design, interpretation of the findings, and critical revision of the manuscript. All authors reviewed and approved the final manuscript.

Abstract

Background: The phase angle (PhA) and extracellular water (ECW)–to–total body water (TBW) ratio serve as indicators of cell membrane integrity and body fluid balance in older adults.

Objective: This study examined the domain-specific associations of physical activity (PA) with PhA and the ECW-to-TBW ratio.

Methods: A nationally representative sample of 5211 adults aged 50 years and older was analyzed. Weekly amounts of moderate-to-vigorous PA (MVPA) in leisure-time, occupational, and transport-related domains were assessed using the Global Physical Activity Questionnaire. A bioelectrical impedance analyzer was used to measure PhA (°) and the ECW-to-TBW ratio (%). Linear regression analyses were conducted.

Results: For leisure-time PA, compared with 0 min/week, participating in 150 to 299 min/week and ≥300 min/week of MVPA was associated with 0.08 (95% CI 0.02-0.14) and 0.13 (95% CI 0.06-0.20) degrees higher PhA, respectively. Additionally, compared with 0 min/week, engaging in 150 to 299 min/week and ≥300 min/week of MVPA was associated with –0.11 (95% CI –0.19 to –0.03) and –0.15 (95% CI –0.22 to –0.07) percentage points lower ECW-to-TBW ratio, respectively. For transport-related PA, compared with 0 min/week, engaging in ≥300 min/week of MVPA was negatively associated with the ECW-to-TBW ratio (β=–0.07, 95% CI –0.14 to –0.01). Occupational PA showed no clear associations with PhA or the ECW-to-TBW ratio.

Conclusions: While the observed associations were modest, the associations of PA with both PhA and the ECW-to-TBW ratio differed across PA domains. Specifically, leisure-time PA was positively associated with PhA and inversely associated with the ECW-to-TBW ratio. These findings highlight the potential role of leisure-time PA in improving bioelectrical markers of cellular health and fluid distribution.

Introduction

Physical activity (PA) is recognized as a major priority in promoting public health in older adults. While the World Health Organization (WHO) recommends that adults participate in ≥150 min/week of moderate-to-vigorous physical activity (MVPA), a concerning proportion of the global population exhibits low levels of PA [1]. For example, a recent study reported that insufficient PA was observed in 31.3% of the global population in 2022, representing a gradual increase over the past decades [1]. In South Korea, sedentary lifestyles remain a significant public health concern. Despite various governmental policies and campaigns to promote PA, 54.5% of adults did not meet the WHO PA guidelines in 2020 [2], a prevalence that has continued to rise over recent decades [3]. Furthermore, older adults in South Korea were significantly less likely to engage in PA, and the decreasing trend was particularly steep among the population aged 50 years and older [3].

XSL•FO
RenderX

The health benefits of PA for older adults are well established. PA is associated with lower risks of overall and cardiovascular disease mortality in older adults [4]. The mechanisms underlying these health benefits can be attributed to multiple factors, including improvements in metabolic profiles, muscle strength and function, and psychological well-being [5]. However, accumulating evidence suggests that the effects of PA vary depending on the domain and context in which it is performed—a phenomenon referred to as the "PA paradox" [6,7]. For instance, studies have shown that reductions in the risks of all-cause mortality and cardiovascular disease are most pronounced for leisure-time physical activity (LTPA) compared with occupational physical activity (OPA) or transport-related physical activity (TRPA) [8-10]. Furthermore, OPA was linked to an elevated risk of mortality [10]. Despite the existing evidence regarding the "PA paradox," differential associations between PA domains and body composition or fluid status have rarely been investigated.

The phase angle (PhA) and extracellular water (ECW)–to–total body water (TBW) ratio, both determined using bioelectrical impedance analysis (BIA), serve as biomarkers of body fluid distribution and cellular function [11]. While PhA reflects cellular membrane integrity, the ECW-to-TBW ratio primarily reflects electrolyte balance and edema status [11,12]. Adverse health conditions, such as malnutrition, edema, systemic inflammation, and low skeletal muscle mass, are associated with lower PhA and higher ECW-to-TBW ratios [11,13,14]. Moreover, low PhA and high ECW-to-TBW ratios have been linked to increased mortality risk among older adults [15-17]. Therefore, PhA and the ECW-to-TBW ratio are regarded as important biomarkers of health status in recent literature.

PA substantially affects both body fluid distribution and body composition by reducing body fat and improving muscle quality in older adults [18-20]. These physiological adaptations can influence BIA-derived parameters, including PhA and the ECW-to-TBW ratio. Prior studies, for instance, reported a positive association between total weekly PA and PhA, along with a negative association with the ECW-to-TBW ratio [18-20]. However, whether the associations of PA with PhA or the ECW-to-TBW ratio differ across PA domains in older adults has been rarely examined. Specifically, no previous studies have investigated how LTPA, OPA, and TRPA are differentially associated with PhA and the ECW-to-TBW ratio. To address this research gap, this study investigated the associations of LTPA, OPA, and TRPA with PhA and the ECW-to-TBW ratio in a nationwide sample of older adults in South Korea. Specifically, we hypothesized that (1) LTPA and TRPA would be positively associated with PhA and inversely associated with the ECW-to-TBW ratio, and (2) OPA would be inversely associated with PhA and positively associated with the ECW-to-TBW ratio.

Methods

Study Population

This study used a cross-sectional design, with the study sample drawn from the Korea National Health and Nutrition Examination Survey (KNHANES). The Korea Disease Control and Prevention Agency (KDCA) administers the KNHANES annually, providing a nationally representative sample of the Korean population. A multistage clustered probability sampling methodology was used to include participants, ensuring representation of the entire Korean population [21]. In this study, datasets from the 2022 and 2023 cycles of the KNHANES were used, during which BIA was performed on participants. Note that, owing to the cross-sectional study design, the temporal relationship between the exposure variables (PA domains) and the outcomes (PhA and the ECW-to-TBW ratio) could not be established, which limits the ability to draw causal inferences from the study findings. A total of 6804 adults aged 50 years and older participated in the 2022 and 2023 survey years of the KNHANES. Individuals meeting any of the following exclusion criteria were excluded: (1) those with pacemakers or implantable cardioverter-defibrillators, (2) pregnant women, (3) individuals with prosthetic limbs, and (4) those who refused or were unable to undergo BIA. In total, 5742 (84.4%) adults participated in BIA. After further excluding participants with missing data, a final sample of 5211 (76.6%) adults was included in this analysis.

Ethical Considerations

All participants provided written informed consent. The protocols of the 2022 and 2023 KNHANES were approved by the institutional review board of the KDCA (2018-01-03-4C-A, 2022-11-16-R-A).

Physical Activity

The Korean version of the Global Physical Activity Questionnaire (K-GPAQ) was used to measure the weekly amounts of total PA, LTPA, OPA, and TRPA. The K-GPAQ has demonstrated good reliability and validity for assessing PA among the Korean population [22]. The questionnaire evaluates PA in 3 domains: LTPA, OPA, and TRPA. LTPA was assessed using the following questions: "Do you regularly participate in vigorous-intensity sports, exercise, or leisure activities that cause you to become significantly out of breath or make your heart beat very fast for at least 10 consecutive minutes?" (vigorous PA) and "Do you regularly participate in moderate-intensity sports, exercise, or leisure activities that cause you to become slightly out of breath or make your heart beat somewhat faster for at least 10 consecutive minutes?" (moderate PA). OPA was assessed using the following questions: "Does your job involve vigorous-intensity physical activity that causes you to become significantly out of breath or make your heart beat very fast for at least 10 consecutive minutes?" (vigorous PA) and "Does your job involve moderate-intensity physical activity that causes you to become slightly out of breath or make your heart beat somewhat faster for at least 10 consecutive minutes?" (moderate PA). TRPA was assessed using the following question: "Do you walk or cycle for transportation (eg, commuting to work, shopping, running errands, attending religious services, or going to or from school or private academies) for at least 10 consecutive minutes?" (moderate PA). For each question, the duration of each session and the number of sessions per week were recorded. The weekly amount of MVPA for LTPA, OPA, and TRPA was then calculated using the following equation:

XSL•FO
RenderX

MVPA(per week)=2×Vigorous PA(per week)+Moderate PA(per week)

Total PA was calculated as the sum of MVPA across the 3 domains—LTPA, OPA, and TRPA. Finally, for each PA domain, PA levels were divided into 4 groups: 0, 1 - 149, 150 - 299, and ≥300 min/week, in accordance with the WHO PA guidelines [23].

PhA and ECW-to-TBW Ratio

PhA and the ECW-to-TBW ratio were measured using a multifrequency bioelectrical impedance analyzer (InBody 970; Biospace). The InBody 970 has demonstrated good validity for assessing body composition [24]. Moreover, measurements obtained from the InBody 970, including PhA, show high reliability and are comparable with results from other BIA devices [25]. Before the assessment, participants fasted for at least 8 hours. After removing all accessories and digital devices, they stood barefoot on the InBody 970 while holding the hand electrodes. All BIA procedures were supervised by trained health professionals from the KDCA. Whole-body PhA was recorded to the nearest 0.1° at 50 kHz, and ECW, intracellular water (ICW), and TBW were recorded to the nearest 0.1 L. Both PhA (°) and the ECW-to-TBW ratio (%) were analyzed as continuous variables.

Covariates

The confounders included the following sociodemographic characteristics: sex, age, educational attainment (middle school or below, high school, or college or above), income (lowest, low, high, or highest), marital status (married, unmarried, or others), smoking status (no or yes), alcohol use (no or yes), hypertension (no or yes), diabetes (no or yes), chronic kidney disease (no or yes), and BMI (kg/m^2). However, because of the lack of available data, several important confounders, including dietary intake, inflammatory markers, and medication use, which may influence body composition and fluid status, could not be included in the analyses. This limitation may have resulted in residual confounding.

Statistical Analysis

Sample characteristics were summarized according to total PA levels. Linear regression models were applied to evaluate the associations of PA levels with both PhA and the ECW-to-TBW ratio, using β coefficients and 95% CIs. The normality of PhA and the ECW-to-TBW ratio was confirmed through visual inspection of histograms and Q-Q plots. First, the associations of total PA with PhA and the ECW-to-TBW ratio were evaluated. Second, the associations of LTPA, OPA, and TRPA with PhA and the ECW-to-TBW ratio were examined. Both crude and fully adjusted models were fitted. For further analyses, the PA variables were treated as continuous variables in the model. Additionally, the nonlinear associations between total PA and each domain of PA with PhA and ECW-to-TBW were examined using the restricted cubic spline function with 4 knots [26]. Statistical analyses were performed using R (version 4.5.0; R Foundation for Statistical Computing). The *survey* package and its function *svyglm* were used to account for the sampling design of the KNHANES [27].

Compared with the included participants, those with missing values were more likely to be older, have lower levels of education and income, have lower PhA values, and have a higher ECW-to-TBW ratio (Table S1 in Multimedia Appendix 1). To mitigate this selection bias, for sensitivity analyses, multiple imputation was performed to handle missing data using the R package *mice* [28]. Specifically, 20 complete datasets were generated using the multivariate imputation by chained equations method, and estimates from each dataset were combined using Rubin rules.

Results

Among the 5211 participants, 31.7% (n=1650), 28.7% (n=1496), 19.2% (n=1000), and 20.4% (n=1065) engaged in 0, 1 - 149, 150 - 299, and ≥300 min/week of MVPA, respectively (Table 1). Participants with higher levels of total PA tended to be younger, have higher education and income levels, and not have hypertension, diabetes, or chronic kidney disease. The mean PhA values were 5.0° (SD 0.7), 5.0° (SD 0.7), 5.1° (SD 0.7), and 5.2° (SD 0.7) for those reporting 0, 1 - 149, 150-299, and ≥300 min/week of MVPA, respectively. The corresponding mean ECW-to-TBW ratios were 38.7% (SD 0.8), 38.4% (SD 0.8), 38.5% (0.7), and 38.4% (SD 0.7), respectively.

In the fully adjusted model (Table 2), compared with 0 min/week of MVPA, ≥300 min/week of MVPA was positively associated with PhA (β=0.08, 95% CI 0.04-0.13). Compared with 0 min/week, the ECW-to-TBW ratio was negatively associated with 150 - 299 min/week of MVPA (β=–0.08, 95% CI –0.14 to −0.03), and ≥300 min/week of MVPA (β=–0.11, 95% CI –0.15 to –0.06). Therefore, total PA showed a linear positive association with PhA and a linear negative association with the ECW-to-TBW ratio, even after adjustment for covariates.

[c]ECW: extracellular water.

[d]TBW: total body water.

Table . Associations of total physical activity (PA) with the phase angle and extracellular water (ECW)–to–total body water (TBW) ratio.

Total PA (MVPA[a])	Phase angle (°)		ECW-to-TBW ratio (%)	
	Crude model, β (95% CI)	Adjusted model, β (95% CI)	Crude model, β (95% CI)	Adjusted model, β (95% CI)
0 min/wk	Reference	Reference	Reference	Reference
1-149 min/wk	−0.02 (−0.09 to 0.04)	0.02 (−0.01 to 0.06)	−0.03 (−0.09 to 0.03)	−0.04 (−0.08 to 0.01)
150-299 min/wk	0.09 (0.02 to 0.17)	0.04 (−0.01 to 0.09)	−0.19 (−0.27 to −0.12)	−0.08 (−0.14 to −0.03)
≥300 min/wk	0.23 (0.16 to 0.30)	0.08 (0.04 to 0.13)	−0.28 (−0.35 to −0.21)	−0.11 (−0.15 to −0.06)

[a]MVPA: moderate-to-vigorous physical activity.

Table 3 presents the associations of the levels of LTPA, OPA, and TRPA with both PhA and the ECW-to-TBW ratio. For LTPA, compared with 0 min/week, engaging in 1-149, 150-299, and ≥300 min/week of MVPA was associated with 0.02 (95% CI –0.03 to 0.06), 0.08 (95% CI 0.02-0.14), and 0.13 (95% CI 0.06-0.20) degrees higher PhA, respectively. In addition, compared with 0 min/week, participating in 1-149, 150-299, and ≥300 min/week of MVPA was associated with –0.06 (95% CI –0.12 to −0.00), –0.11 (95% CI –0.19 to −0.03), and –0.15 (95% CI –0.22 to −0.07) percentage points lower ECW-to-TBW ratio, respectively. For TRPA, compared with 0 min/week, engaging in ≥300 min/week of MVPA was negatively associated with the ECW-to-TBW ratio (β=–0.07, 95% CI –0.14 to –0.01). However, no clear relations were observed between TRPA and the PhA. Finally, OPA showed no significant associations with either PhA or the ECW-to-TBW ratio. Therefore, the associations with both PhA and the ECW-to-TBW ratio were most consistent for LTPA, whereas TRPA was associated only with a lower ECW-to-TBW ratio, and OPA was not significantly associated with either outcome.

Table . Associations of leisure-time, occupational, and transport-related physical activity with the phase angle and extracellular water (ECW)–to–total body water (TBW)' ratio

	Phase angle (°)		ECW-to-TBW ratio (%)

[a]LTPA: leisure-time physical activity.

[b]MVPA: moderate-to-vigorous physical activity.

[c]OPA: occupational physical activity.

[d]TRPA: transport-related physical activity.

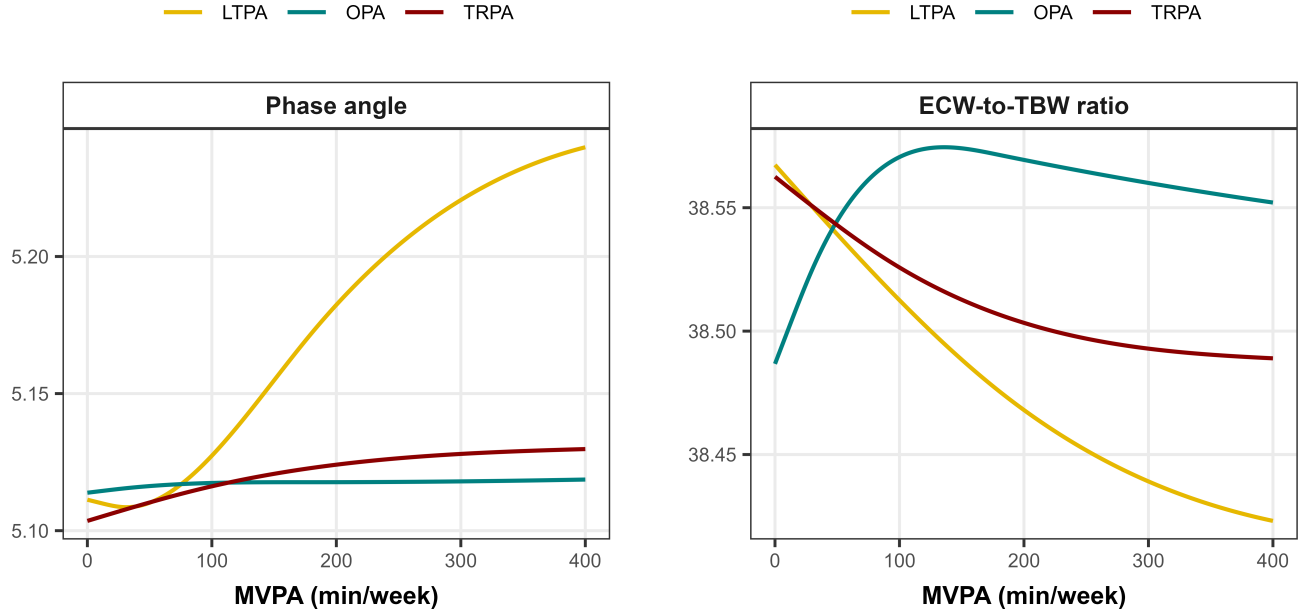

Figure 1 shows the nonlinear associations of LTPA, OPA, and TRPA with PhA and the ECW-to-TBW ratio based on restricted cubic spline models. For PhA, a pronounced positive association was observed with LTPA. TRPA showed a weak positive association, whereas OPA exhibited a flat pattern, indicating no clear association with PhA. For the ECW-to-TBW ratio, LTPA demonstrated the strongest inverse association, whereas TRPA was also negatively associated with the ECW-to-TBW ratio. In contrast, OPA showed a positive association up to

XSL•FO
RenderX

approximately 100 min/week of MVPA, beyond which the association was no longer apparent.

Sensitivity analyses based on the imputed datasets confirmed that total PA was directly associated with PhA and inversely associated with the ECW-to-TBW ratio (Table S2 in Multimedia Appendix 1). The slight differences between the estimates in Table 2 and Table S2 in Multimedia Appendix 1 reflect the differences in analytic approaches between complete-case analysis and multiple imputation, while the estimates are comparable. Moreover, the associations of LTPA, OPA, and TRPA with both PhA and the ECW-to-TBW ratio remained consistent in the sensitivity analyses (Table S3 in Multimedia Appendix 1). When PA was analyzed as a continuous variable (Table S4 in Multimedia Appendix 1), each 150-min/week increment in MVPA from LTPA, OPA, and TRPA was associated with changes in PhA (°) of 0.03 (95% CI 0.01-0.05), 0.00 (95% CI −0.01 to 0.01), and 0.01 (95% CI −0.01 to 0.02), respectively. The corresponding changes in the ECW-to-TBW ratio (%) were −0.03 (95% CI −0.05 to −0.01), 0.01 (95% CI −0.01 to 0.02), and −0.02 (95% CI −0.04 to −0.01), respectively, after adjustment for covariates (model 2).

Figure 1. Nonlinear associations of leisure-time, occupational, and transport-related physical activity with phase angle and the extracellular water (ECW)–to–total body water (TBW) ratio, estimated using restricted cubic spline functions. The models were adjusted for sex, age, education, income, marital status, smoking status, alcohol consumption, hypertension, diabetes, chronic kidney disease, and BMI. LTPA: leisure-time physical activity; MVPA: moderate-to-vigorous physical activity; OPA: occupational physical activity; TRPA: transport-related physical activity.

Discussion

Principal Findings

This study investigated the domain-specific associations of PA with PhA and the ECW-to-TBW ratio in older adults. Total PA was positively associated with PhA and negatively associated with the ECW-to-TBW ratio in older adults. Among the PA domains, LTPA showed the most consistent associations with both PhA and the ECW-to-TBW ratio, whereas high levels of TRPA (≥300 min/week) were negatively associated only with the ECW-to-TBW ratio. Specifically, the nonlinear models demonstrated that the positive association between LTPA and PhA, as well as the negative association between LTPA and the ECW-to-TBW ratio, followed a largely linear pattern without a clear threshold. In contrast, OPA showed no clear associations with either PhA or the ECW-to-TBW ratio.

The results of this study are consistent with prior research demonstrating that PA is positively associated with PhA and negatively associated with the ECW-to-TBW ratio. Studies conducted in South Korea and Poland showed that self-reported PA was associated with a higher PhA among adults [19,29]. Furthermore, previous studies have consistently confirmed the positive association between objectively measured PA and PhA [20,30,31]. Evidence from a meta-analysis also supports the finding that PA is positively associated with PhA [32]. Conversely, previous research reported negative associations between PA levels and the ECW-to-TBW or ECW-to-ICW ratios [18,33]. A recent study using the doubly labeled water method found that PA levels were directly associated with PhA and inversely associated with the ECW-to-ICW ratio [34]. Building on this evidence, the present study provides novel insights by elucidating that the associations between PA and PhA and the ECW-to-TBW ratio vary substantially across PA domains.

It is hypothesized that complex physiological and biochemical mechanisms may underlie the associations between PA and both PhA and the ECW-to-TBW ratio. One of the biological pathways through which PA is linked to BIA-measured outcomes may be associated with the mitigation of systemic inflammation. Long-term engagement in PA was linked to lower levels of circulating inflammatory markers, including C-reactive protein, interleukin-6, and tumor necrosis factor α [35,36]. Chronic inflammation and oxidative stress can induce cellular damage, such as structural injury, membrane disruption, and apoptosis, thereby lowering PhA. Consequently, regular PA may be associated with higher PhA values [12]. Furthermore, PA promotes favorable changes in body composition by

XSL•FO
RenderX

lowering body fat percentage and increasing skeletal muscle mass [37]. Such physiological adaptations to PA are also associated with a lower ECW-to-TBW ratio, reflecting improved intracellular-to-extracellular water balance [38].

Although this study found substantial associations between PA domains and PhA and the ECW-to-TBW ratio, the magnitudes of these associations were modest; for example, engaging in ≥300 min/week of LTPA was associated with a 0.13° higher PhA and a 0.2% lower ECW-to-TBW ratio compared with the 0 min/week. The modest effect sizes of the observed associations may be because BIA-derived profiles are influenced by a wide range of underlying demographic and health-related factors, including sex, age, and chronic conditions. Although these associations may appear modest at the individual level (ie, a 0.13° higher PhA and a 0.2% lower ECW-to-TBW ratio), they correspond to approximately 2 SDs of the distributions of PhA and the ECW-to-TBW ratio in our study population. Therefore, these differences may have meaningful implications at the population level.

The findings that the associations between PA and both PhA and the ECW-to-TBW ratio differed across PA domains warrant attention. These results align with the existing "PA paradox" hypothesis, which posits that the beneficial health effects of PA are primarily derived from LTPA [39]. A study of Korean adults reported that while LTPA was linked to lower high-sensitivity C-reactive protein levels, OPA was associated with higher levels [40]. Furthermore, a recent study of older adults in South Korea found that LTPA was positively associated with the skeletal muscle mass index, whereas OPA showed no significant association [41]. Although multiple factors may contribute to the differential associations of PA domains with health outcomes, one possible explanation is that LTPA generally involves the free and coordinated use of muscle groups throughout the body, whereas OPA often requires repetitive use of specific muscle groups [42]. Evidence from these studies suggests that LTPA is associated with beneficial physiological adaptations, which may explain why LTPA exhibited the most consistent associations with both PhA and the ECW-to-TBW ratio. Particularly for LTPA, individuals can freely determine the frequency and intensity of their activity. Therefore, those with better underlying health status may be more likely to engage in more frequent and vigorous LTPA, which may increase the potential for reverse causation and contribute to the stronger associations observed in the present study. Additionally, individuals with high levels of OPA may be more likely to have lower socioeconomic status and engage in occupations involving substantial physical demands and work-related stress, factors that may be associated with lower PhA values and higher ECW-to-TBW ratios. Such coexposure may have obscured the independent association between OPA and these BIA parameters. Furthermore, OPA was assessed using self-reported questionnaires rather than objective measures, which may not accurately capture the intensity, posture, and frequency of OPA. This limitation may have introduced measurement error and further attenuated the observed associations. Future longitudinal studies are needed to confirm the causal relationship.

The present study has several limitations. First, because of its cross-sectional design, the present study cannot establish the causal effects of PA on PhA and the ECW-to-TBW ratio. For instance, the possibility of reverse causation should be acknowledged; individuals in better physical condition, indicated by higher PhA and lower ECW-to-TBW ratios, may be more likely to engage in PA. This may be particularly relevant for LTPA, as individuals can freely determine the levels and intensity of PA. Therefore, the possibility of reverse causation may be greater for LTPA than for other PA domains and may have contributed to the stronger observed associations. Therefore, the temporal relationship between PA and both PhA and the ECW-to-TBW ratio should be clarified in future longitudinal studies. Second, while the K-GPAQ is a validated tool for evaluating PA among the Korean population and offers the advantage of differentiating LTPA, OPA, and TRPA, potential measurement errors arising from recall or social desirability bias should be recognized. A previous study reported that older adults tend to overreport their levels of PA when assessed using the GPAQ compared with accelerometer-based measurements [22]. Although self-reported and objectively measured PA were significantly correlated, the strength of this correlation was only modest, highlighting the inherent limitations and potential measurement error associated with questionnaire-based PA assessment [22]. Furthermore, the degree of measurement error may vary across PA domains, potentially resulting in differential misclassification and influencing the observed domain-specific associations. It should also be noted that, among older adults, the distinction between TRPA and LTPA may not be clear. Future studies would benefit from using objective measures, such as accelerometers, to improve accuracy. Third, this study did not account for several unmeasured confounders due to the lack of available data. For example, factors such as dietary intake, inflammatory biomarkers, and the use of medications that influence body composition and fluid status were not adjusted for in the regression models. Future in-depth analyses should incorporate these variables to elucidate the physiological mechanisms underlying the associations between PA and both PhA and the ECW-to-TBW ratio.

Despite these limitations, the study has some strengths. To the best of our knowledge, this is the first study to demonstrate domain-specific associations between PA and both PhA and the ECW-to-TBW ratio. Furthermore, the results were derived from a nationally representative sample of middle-aged and older adults, thereby ensuring the generalizability of the results.

Conclusions

This study revealed that PA is differentially associated with PhA and the ECW-to-TBW ratio according to its domain in older adults in South Korea. LTPA demonstrated a notable positive association with PhA and a negative association with the ECW-to-TBW ratio, even at lower levels of activity. The negative association between TRPA and the ECW-to-TBW ratio was observed at higher levels (≥300 min/week), whereas OPA showed no clear associations with either PhA or the ECW-to-TBW ratio. Future research should use longitudinal study designs and objective measures of PA to establish the

XSL•FO
RenderX

temporal sequence of the observed associations and improve the accuracy of PA assessment.

Abstract

Background: Low levels of physical activity (PA) increase dementia risk, and for middle-aged and older adults with co-occurring cognitive concerns and mental health symptoms, dementia risk increases further. Despite clinical trials showing lower adherence to PA interventions in high-risk groups, there is a sparsity of interventions tailored to support unique behavior change needs. In EXCEL (Exercise for Cognitive Health) phase 1, we developed a model to understand the needs of this population and identified tailoring requirements to enhance engagement. Here we report the findings of a pilot online intervention designed to support middle-aged and older adults with subjective cognitive decline or mild cognitive impairment and mild to moderate symptoms of depression or anxiety to meet PA guidelines.

Objective: We aimed to measure (1) efficacy of the intervention in promoting adoption of PA in line with national guidelines, (2) acceptability, feasibility, and safety of the intervention, (3) changes to dementia risk, PA levels, mental health symptoms, and stages of change, and (4) changes in potential cognitive mechanisms of change.

Methods: A pilot individual 12-week online home-based PA intervention. Participants aged 45-80 years, experiencing both cognitive and mild-to-moderate anxiety and depression symptoms, were prescribed individually tailored PA programs combining aerobic and strength PA, plus balance training as indicated, with fortnightly online coaching.

Results: A total of 55 participants were enrolled (46 females/9 males; mean age 62.2, SD 7.6 y). The intervention was effective; at baseline, only 3 of 55 (6%) participants met all applicable PA guidelines, compared to 24 of 55 (44%) participants post intervention (P<.001). Participants were at least 8 times more likely to meet the age-appropriate guidelines for aerobic, strength, and balance activities after the intervention. Retention rates were high (95% completion rate), and feedback indicated 98% found the program useful. Safety was successfully monitored by a clinical panel via email, using a system of alerts. Dementia risk was reduced (d=−0.32, P=.008), and reductions in depression, anxiety, and stress scores were large and clinically meaningful (d=−1.31, d=−0.89, and d=−1.18, respectively; all P<.001). Over half of the cohort (27 participants) transitioned to a higher stage of change at postintervention. Improvements in action planning (d=0.66, P<.001) and positive outcome expectancies (d=0.33, P=.01) indicate potential cognitive mechanisms of change.

XSL•FO
RenderX

Conclusions: Our findings showed that this tailored, home-based online intervention successfully supports an at-risk cohort of aging adults to adopt PA, in line with national guidelines. The intervention was acceptable, feasible, and safe and led to significant reductions in dementia risk and mental health symptoms and was associated with progression through stage of change. Reflecting the Capability, Opportunity, and Motivation Behavior model underlying the intervention design, improvements in action planning and outcome expectancy appeared to play a role in bridging the PA intention-behavior gap.

Introduction

Low physical activity (PA) levels are an established modifiable risk factor for dementia [1-3]. Depression and anxiety are also linked to dementia risk [4,5] and are associated with low levels of PA and other dementia risk factors [6]. The presence of cognitive concerns further adds to dementia risk, beyond the contribution of mood symptoms [7-9]. Accordingly, aging individuals who are concerned about their cognition and experience depressive or anxiety symptoms are considered an at-risk group for dementia [1,3,10]. The World Health Organization has emphasized the critical importance of directing dementia risk reduction (DRR) implementation research toward such at-risk populations, recognizing their heightened vulnerability and the urgent need for tailored and targeted strategies [11].

In 2018, our group developed PA guidelines for older adults living with mild cognitive impairment (MCI) or subjective cognitive impairment [12], complementing existing adults' and older adults' PA guidelines [13,14]. These guidelines recommend 150 minutes of moderate aerobic PA plus 2 strength sessions (of approximately 30 min each) per week, along with balance exercises as often as possible for older adults [12,13]. However, research shows that consumer awareness of PA guidelines is very low; none of the middle-aged to older adults interviewed by our team were aware of the guidelines [15], consistent with similarly low awareness internationally [16,17]. Implementation research is now vital to ensure individuals in middle to later life with mental and cognitive health symptoms can benefit from these guidelines, and from DRR interventions more broadly.

Symptoms of depression and anxiety, however, are associated with lower adherence and poorer outcomes in both PA and DRR intervention trials, as well as being a barrier to participation [6,18-20]. Tailored interventions for this population are essential to reduce dementia risk [11,21]. In a prior study [14], our team conducted a comprehensive analysis integrating data from semistructured interviews with 21 participants, a review of existing literature, and the Capability, Opportunity, and Motivation Behavior (COM-B) model to identify three behavior-change areas critical for this high-risk group: (1) emotional regulation, (2) overcoming barriers to turning intention into action, and (3) building confidence in one's abilities [14]. These findings informed a model outlining strategies for tailoring PA interventions to the emotional and cognitive needs of this cohort. We additionally identified engagement preferences with information and communications technology [15,22], which was seen as essential to overcome access barriers [23], and technology was frequently cited as a useful tool by our target group for the accountability and connection they sought from PA interventions [15]. Indeed, older people appear to be well placed to benefit from PA interventions, given that we have seen relatively high and rising information and communications technology use in this age group [24]. We used this model [14] as the foundation for developing the EXCEL (Exercise for Cognitive Health) intervention. The PA programs themselves were based on our established work, which has successfully prescribed PA plans to older adults [25]. The EXCEL intervention was finalized at the beginning of a period of COVID-19–related lockdown in Victoria, Australia. As social isolation is linked to heightened experiences of symptoms of depression and anxiety [26,27] and a higher prevalence of these conditions [28], interventions for individuals with poorer mental health became more crucial than ever, and PA engagement and delivery were essential.

In this paper, we present the findings of EXCEL, a tailored 12-week home-based PA-delivered intervention designed to help middle-aged and older adults living with mild to moderate symptoms of depression, anxiety, or stress and cognitive concerns in adopting PA guidelines for DRR. Our primary hypothesis was that EXCEL would be associated with improved adherence to PA guidelines. We further hypothesized that the program would be acceptable, feasible, and safe, and associated with reductions in dementia risk and mood symptoms, and promote progression through stages of change. We further aimed to explore whether the intervention impacted potential cognitive mechanisms of behavior change.

Methods

Study Design

A single-arm pilot study of a 12-week online intervention combining PA prescription and individualized coaching. The current study measured the efficacy of the intervention for helping participants to meet age-appropriate PA guidelines [12,14], with secondary outcomes exploring acceptability, feasibility, and safety, and whether the intervention modified dementia risk, overall PA levels, mental health symptoms, and stages of change. We examined pre-post changes in measures of cognitive mechanisms of behavior change.

RenderX

Ethical Considerations

This study received ethical approval from the University of Melbourne Human Research Ethics Committee (2021-20479-16470-3). All published data is deidentified. Participants provided written informed consent to take part in this study before screening. Participants kept all programs and equipment provided during this study but did not receive other compensation for participating.

Participants

Participants were eligible for inclusion if they were aged between 45 and 80 years; English-speaking; living in the community; had access to a phone and/or internet; reported concerns about their cognition (with or without objective cognitive decline) but not dementia; and experienced mild to moderate symptoms of depression, anxiety, or stress (measured using the short-form Depression Anxiety Stress Scales [DASS-21] [29]). Concerns about cognition were reported by a "yes" response to either of the questions: "Do you think your memory or thinking has changed?" or "Do you think your memory or thinking is worse than for other people your age?" Exclusion criteria were lack of capacity to provide informed consent; inability to read or write in English; diagnosis of dementia or a score indicative of dementia (27 or lower) on the Telephone Interview for Cognitive Status [30]; scores in the severe category or higher on either the depression, anxiety, or stress dimensions of the DASS-21 [29]; acute or past history of significant mental illness; current suicidality or history of suicidal attempts within the past 2 years; significant uncorrected sensory impairment; severe mobility impairment (either an inability to walk unaided or a score of 12 or more, indicative of medium to high risk, on the Falls Risk Assessment Tool [31]); any other significant medical condition that would prevent safely undertaking moderate-intensity PA (gauged using the Adult Pre-Exercise Screening System [32] and the Physical Activity Readiness Questionnaire [33]); or a BMI of less than 18.5 or 38 or higher (indicating that they were underweight or very obese). Where applicable, ethnically adjusted BMI indicators were used [34]. Participants were recruited from various sources across Australia, including state-wide seniors' newsletters, university media, general practitioners, online self-registration services (StepUp platform) [35], and a database of volunteers who previously consented to be approached for research. Our target sample size was informed by a 1-sample proportion test [36] based on the AIBL Active Study [25]. To detect a 15% increase in participants meeting moderate-intensity PA guidelines with α=.05 and an expected attrition rate of 30% [37], we calculated a required sample size of 70, which would yield power of 0.80 to detect this effect.

Intervention

EXCEL was a 12-week home-based PA intervention comprising the following resource and support components.

PA Equipment, Guide, and Programs

We developed a PA guide incorporating aerobic, strength, and balance programs tailored to 2 age streams: 45 - 59 years (based on the standard national PA guidelines [14]) and 60 - 80 years (based on national guidelines for older adults with MCI or subjective cognitive decline [12]). While warm-up and cool-down programs were identical for both streams, aerobic and strength programs were customized. Within each stream, participants received either a starter or intermediate program based on their health, abilities, and current activity level. Strength programs differed slightly between males and females. All older age stream participants received a balance program with options for progression. Core program content was developed from successful past studies, including the INDIGO (Individual Goal-Setting and Volunteer Mentors) study [38] and work by Yang et al [39]. The PA guide (Figure 1) provided structured guidance on increasing duration, intensity, number of sessions, and resistance or weights to meet the PA guidelines in 12 weeks. The program incorporated flexibility, with progression guides suggesting rather than prescribing exercises. Each warm-up and cool-down, strength, and balance program included summary pages for easy reference (Figure 2), plus exercise-specific pages detailing performance instructions, pictures, and links to YouTube (Google LLC) demonstration videos (Figure 3). Along with the PA guide and program, participants received a wearable wrist activity tracker, dumbbells, and resistance bands via post if they did not already own this equipment. Participants had access to an online PA diary hosted on the REDCap (Research Electronic Data Capture; Vanderbilt University) platform [40], which could be printed in hard copy or PDF format upon request.

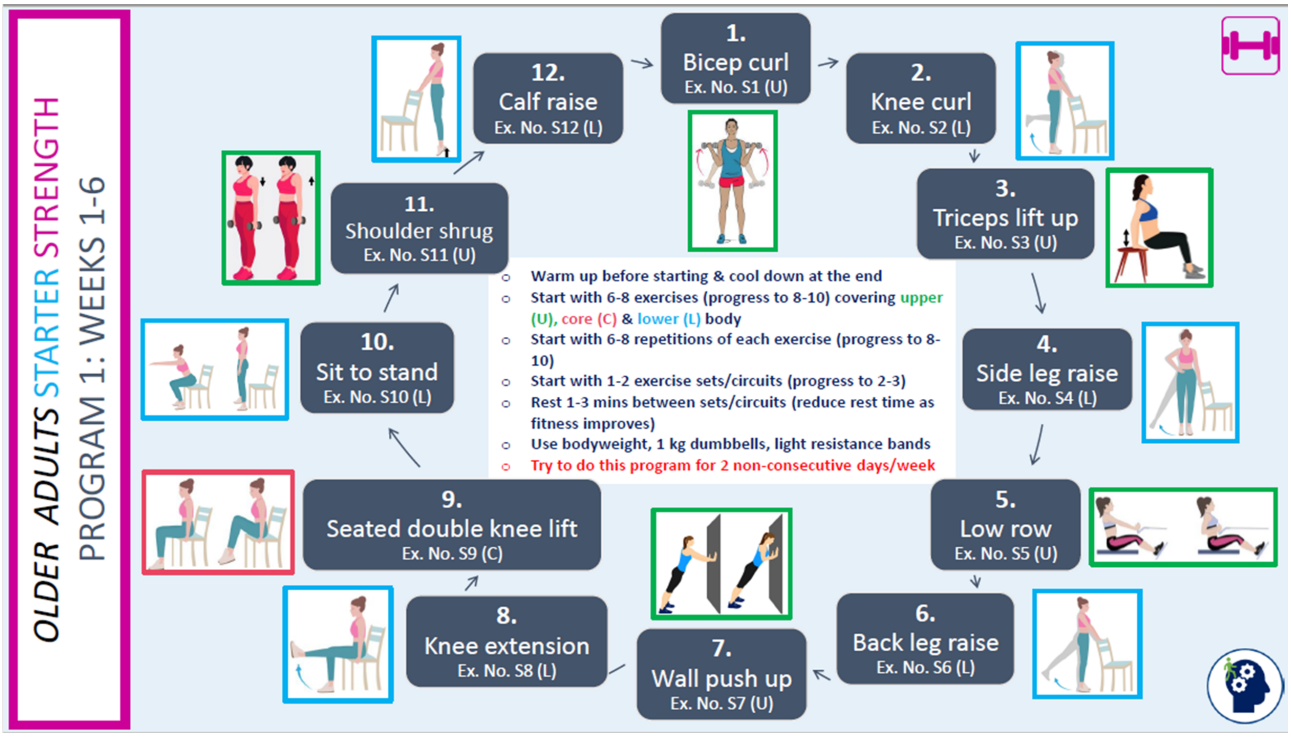
EXCEL Study Part Two

OLDER ADULTS AEROBIC PROGRAM

STARTER LEVEL WALKING (5 DAYS)

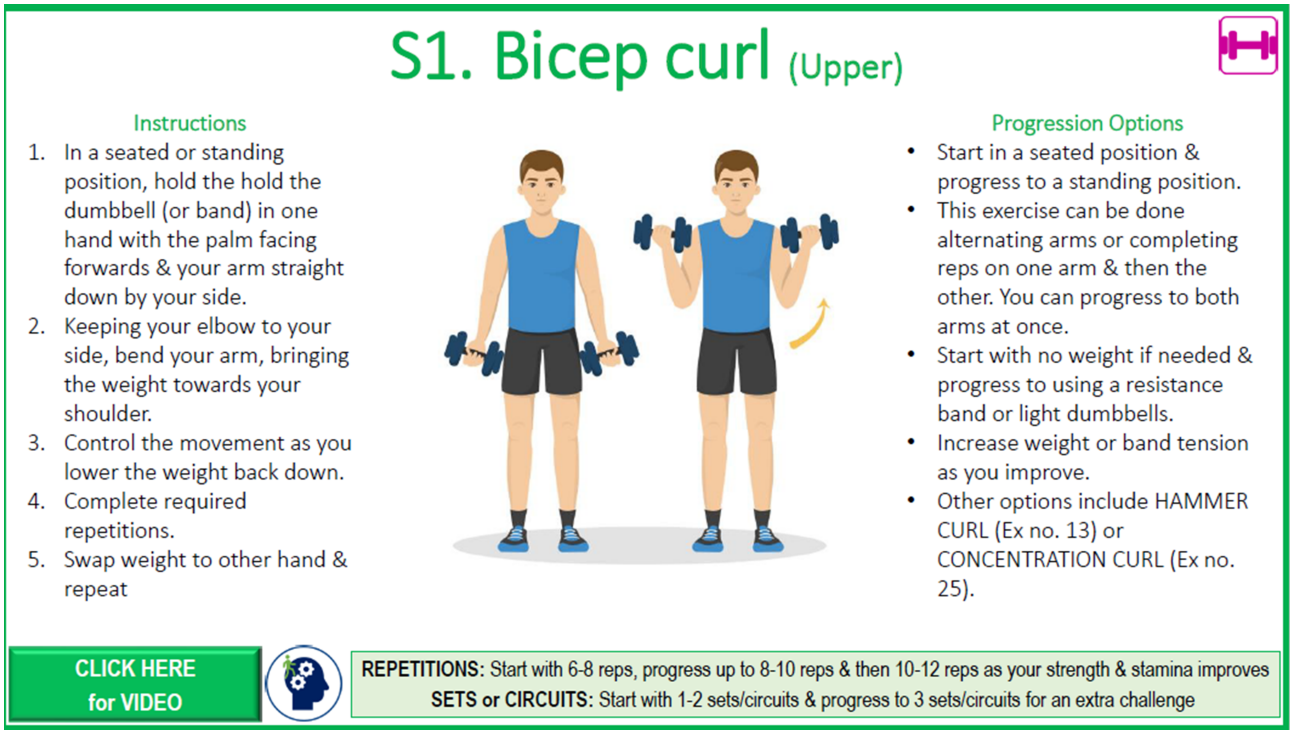
WEEKS 1-12



Aerobic

Try to walk most days. This program is for walking on 5 DAYS EACH WEEK
> In the early weeks you can walk in shorter blocks (10 or 15-minutes) with 1-2 min rest if needed
> You can swap WATER WALKING for walking if you have arthritis or joint issues

WEEKS		WALK PACE	TIME (mins)	EFFORT
1 & 2		Slow pace WALK	25	**LOW:** Easy & not puffing
3 & 4	Warm up:	Slow pace WALK	5	**LOW:** Easy & not puffing
		Slow-mod pace WALK	20	**LOW-MOD:** Easy but breathing a bit more
	Cool down:	Slow pace WALK	5	**LOW:** Easy & not puffing
5 & 6	Warm up:	Slow pace WALK	5	**LOW:** Easy & not puffing
		Moderate pace WALK	20	**MODERATE:** Puffing a little, can easily talk
	Cool down:	Slow pace WALK	5	**LOW:** Easy & not puffing
7 & 8	Warm up:	Slow-mod pace WALK	5	**LOW-MOD:** Easy but breathing a bit more
		Moderate pace WALK	20	**MODERATE:** Puffing a little, can easily talk
	Cool down:	Slow-mod pace WALK	5	**LOW-MOD:** Easy but breathing a bit more
9, 10, 11 & 12	Warm up:	Slow-mod pace WALK	5	**LOW-MOD:** Easy but breathing a bit more
		Moderate-brisk pace WALK	20	**MOD-BRISK:** Puffing a little more still able to talk
	Cool down:	Slow-mod pace WALK	5	**LOW-MOD:** Easy but breathing a bit more



Remember to do your exercises for STRENGTH (at least twice a week) & BALANCE (as often as you can)

Figure 3. Example of a detailed exercise page in an EXCEL study strength program. Ex. no.: exercise number; EXCEL: Exercise for Cognitive Health; reps: repetitions.

Coaching or Support

The online support structure consisted of 3 types of sessions as outlined below.

The introduction session was an approximately 70-minute online videoconference session that familiarized participants with key sections of the PA guide, including guidelines and safety information. Participants received personalized directions from an exercise specialist (JS) and were able to ask questions.

Of fortnightly catch-up sessions, there were online sessions (20 min or less) with EXCEL coaches, who checked participants' diaries, discussed difficulties, and used behavior change strategies tailored to individual needs [22]. These strategies included education, motivation, incentivization, reinforcement, training, environmental restructuring, modeling, and enablement. The 4 EXCEL coaches came from various backgrounds, including psychology, PA, social work, and occupational therapy.

Of exercise specialist sessions, there were as-needed online sessions with the team exercise science specialist (JS) provided extra assistance on exercise elements of the program for participants who requested or required additional support.

Procedure

Figure 4 summarizes the participant procedure. Participants completed a consent form and prescreening survey and proceeded to a screening call (50 min), completing additional measures to confirm eligibility. Eligible participants were assigned to a PA program and scheduled for an introductory session before completing self-report baseline measures (≈40 min). Their general practitioner was notified of their involvement in the PA intervention. Participants completed the DASS-21 again at weeks 4 and 8 (each ≈5 min). Safety was prioritized, with participants scoring in the severe range or higher on any DASS-21 subscale contacted using a safety protocol script. Fortnightly consultation sessions were held between EXCEL coaches and the research team, which consisted of psychiatrists (NTL, TWHC, TR, and EC), a clinical psychologist (KAE), and exercise physiologists (KLC and JS), to monitor participant safety. Following the 12-week program, participants completed self-report postintervention measures (≈40 min) and an evaluation survey (≈8 min) via Zoom.

Outcome Measures

Outcome measures are summarized in Table 1. The primary outcomes reflected successful uptake of age-appropriate PA guidelines, specifically meeting the aerobic recommendation of at least 150 minutes per week of moderate or vigorous intensity activity at follow-up and achieving the full set of PA guidelines encompassing aerobic, strength, and balance activities. Secondary outcomes included acceptability, feasibility, and safety, changes in general dementia risk levels, changes in total moderate-to-vigorous PA that incorporates everyday activities, changes in mental health symptoms, and progression through stage of change. Finally, 2 categories of mechanism-focused outcomes were evaluated. The first relates to potential cognitive mechanisms underpinning exercise behavior change, including shifts in knowledge, motivation, and self-efficacy from pre- to postintervention. The second examined potential mechanisms associated with general dementia risk-reduction behavior change over the same period.

XSL•FO
RenderX

Table . Outcome variables.

Outcome measures	Details
Primary outcomes	• Data for primary outcomes were taken from the CHAMPS[a] questionnaire [41]. For assessing guideline uptake, only purposeful PA[b] was included, that is, PA done with the purpose of doing exercise. This excluded incidental or everyday PAs, such as gardening, housework, etc.
Uptake of aerobic PA guidelines	• Measured by proportion of participants completing 150 minutes or more per week of at least moderate intensity aerobic PA (purposeful PA not including incidental or everyday activities) pre- and postintervention.
Uptake of full PA guidelines	• Measured by the proportion of participants completing 150 minutes or more of at least moderate intensity aerobic PA (purposeful PA not including incidental or everyday activities) as well as 2 or more strength training sessions and at least 1 balance session (older adults only) per week pre- and postintervention.
Secondary outcomes	• Data for secondary outcomes were taken from a range of tools listed below.
Acceptability, feasibility, and safety	• Measured by retention (intervention withdrawals or completions) using a postintervention evaluation questionnaire (developed by the research team to evaluate enjoyment, usefulness, and usability of various elements of the intervention). • Safety was assessed by successful monitoring by a clinical panel using a system of email alerts and a safety protocol.
General dementia risk levels	• Measured by dementia risk and cognitive health scores pre- and postintervention. This tool is a risk assessment calculator used to understand an individual's risk of developing dementia (CogDRisk) [42].
Change in PA	• Measured by overall minutes of moderate to vigorous intensity PA (including everyday relevant activities) pre- and postintervention using CHAMPS [41]. • Measured by overall minutes of any intensity PA (including everyday relevant activities) pre- and postintervention using CHAMPS [41]. • Measured by adherence to PA guidelines in 3 domains (aerobic, strength, and balance) over 12 weeks using self-report PA diary data.
Change in mental health symptoms	• Measured by depression, anxiety, and stress scores pre- and postintervention. This instrument rates these 3 dimensions of mental health (DASS-21[c]) [29].
Changes in change readiness	• Measured by stages of change scores pre- and postintervention including any shift in change stage. This tool assesses an individual's readiness to change a specific behavior (PA) by evaluating their agreement with statements corresponding to different stages of change: precontemplation, contemplation, preparation, action, and maintenance (modified SOC[d] [43]).

XSL•FO
RenderX

Outcome measures	Details
Change in potential exercise-related cognitive mechanisms of exercise behavior change	• Measured by self-efficacy for exercise scores pre- and postintervention. This 9-item scale measures an individual's confidence in their ability to exercise 3 times per week for 20 minutes in the context of 9 different situations that may interfere with exercise. Items are rated from 0 to 10; 0 represents not confident and 10 represents very confident (modified SEES[e] [44]). • Measured by outcome expectations for exercise scores pre- and postintervention. This 13-item scale includes positive and negative subscales and measures the strength of outcome expectations for exercise. It uses a Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree; modified OEES-2[f] [45]). • Measured by exercise benefits and barriers for scores pre- and postintervention. This 43-item scale measures perceptions about benefits or barriers to exercising and uses a Likert-type response ranging from 4 (strongly agree) to 1 (strongly disagree; modified EBBS[g] [46]). • Measured by action planning for exercise scores pre- and postintervention. This scale is used to measure the extent to which individuals plan and commit to actions related to their goals and uses a 6-point Likert scale. Participants respond to items that question specific aspects of planning (ie, "I have a clear plan for how to achieve my goal"; APS[h] [47]).
Change in potential cognitive mechanisms of DRR[i] related behavior change	• Measured by dementia knowledge scores pre- and postintervention (DKAS-subscale D[j] [48]). • Measured by motivation to change dementia risk behavior scores pre- and postintervention. This 27-item scale assesses beliefs and attitudes toward DRR and uses a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree; MCLHB-DRR[k] [49]).

Statistical Analysis

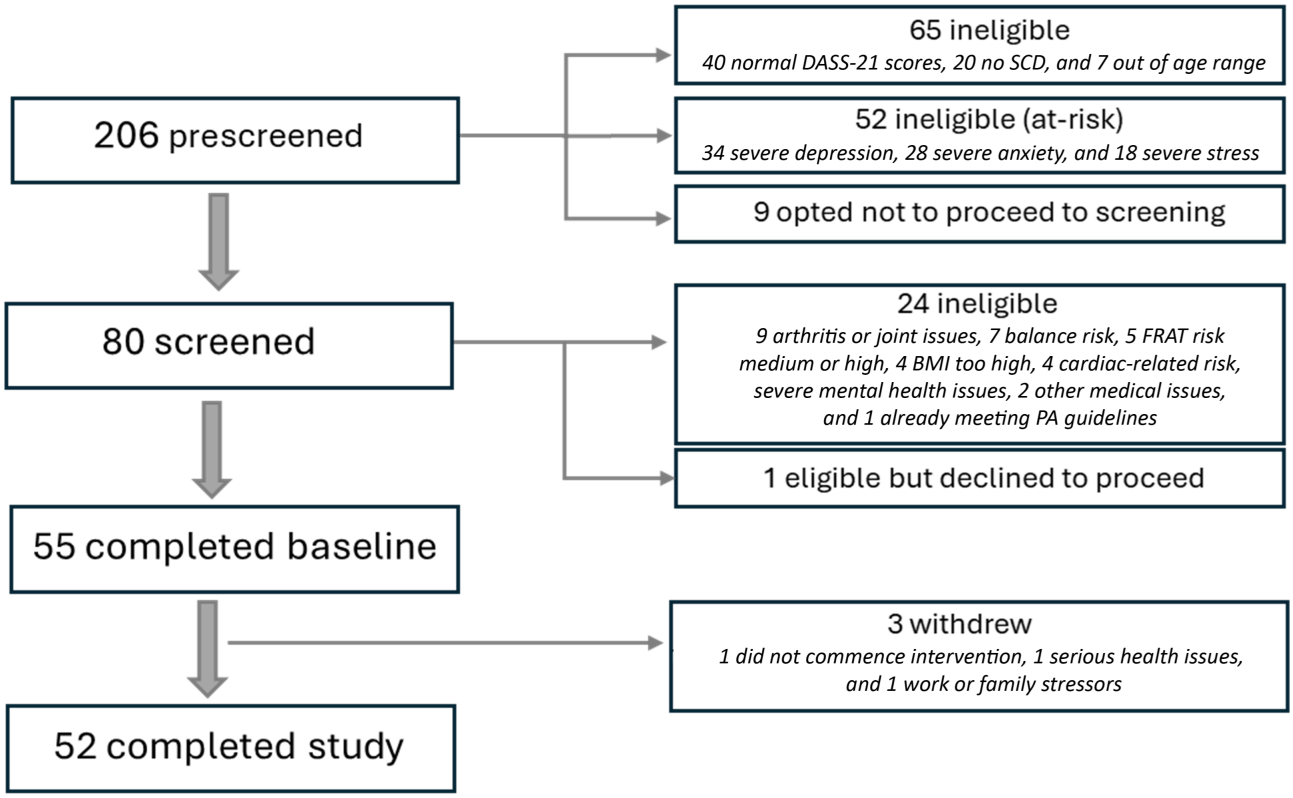
All quantitative data analyses were conducted using SPSS (version 29; IBM Corp) and R (version 4.1; R Foundation). The *lme4* package was used for the mixed-effects modeling [50], and the *emmeans* package was used to calculate the effect sizes [51], while the *coin* package was used for the asymptotic marginal homogeneity test [52]. Standard assumption checks were undertaken for the linear mixed-effects analyses covering residuals, random effects, variance homogeneity, multicollinearity, influence, and missing data patterns and found no departures that would likely affect the findings. Given the single-group pre-post design, key assumptions required for valid causal mediation analysis, including the ability to rule out unmeasured confounders and separate intervention effects from natural temporal change, could not be met. Therefore, we examined pre-post changes in hypothesized mediators descriptively rather than conducting formal mediation analysis.

Descriptive statistics (means, SDs, frequencies, and proportions) were used to describe demographic and outcome measures. The Marginal Homogeneity test, an extension of the McNemar test, was used to compare the proportion of participants who met PA guidelines at baseline to those who met the PA guidelines at postintervention, with the sample restricted to those participants with both baseline and follow-up data. For continuous variables, linear mixed-effects models were used to compare changes in outcome scores from baseline to follow-up, accounting for missing data at follow-up. The models included a fixed effect of time and a random intercept for participants. The Kenward-Roger degrees of freedom approximation was used to calculate *P* values, CIs, and effect sizes. For these models, Cohen *d* effect size was calculated as the mean difference between baseline and follow-up scores divided by the square root of the sum of the intercept (participant) and residual random effect variances [53]. Cohen *d* effect sizes were

XSL•FO
RenderX

interpreted as small (d=0.2), medium (d=0.5), and large (d≥0.8). The Benjamini and Yekutieli [54] approach was used to correct for multiple testing of the primary outcomes and secondary outcomes, respectively. For these analyses, an α of .05 was used for statistical inference.

Adherence to PA Guidelines



Participants' self-reported diaries collected over the 12-week intervention period were used to assess adherence to PA guidelines. No consensus exists on defining PA adherence; similar studies commonly use meeting 2/3 or more of the prescribed PA [55]. We will apply two thresholds: (1) full adherence, defined as meeting the complete guideline each week (>150 min/wk moderate-plus aerobic PA, >2 strength sessions/wk, and for older adults >1 balance session/wk); and (2) 2/3 adherence, defined as >100 minutes per week of aerobic PA, ≥1 strength session per week, and ≥1 balance session per week for older adults. Aggregate total adherence over the 12-week intervention period will use a realistic expectation of 8 or more out of a possible 12 weeks' meeting in full or with 2/3 guidelines.

Results

Participant Demographics

Figure 5 summarizes this study recruitment and screening process; 55 participants were enrolled and completed baseline assessment (46 female/9 male; mean age at screening 62.2, SD 7.6 y). Demographic characteristics are presented in Table 2.

Figure 5. Study recruitment and screening flow diagram. DASS-21: Depression Anxiety Stress Scale short form; FRAT: falls risk assessment tool; PA: physical activity; SCD: subjective cognitive decline.

Preliminary Analysis

We performed sensitivity analyses adding age, gender, baseline depression score, and baseline total minutes of PA as covariates; their inclusion had a negligible effect on the estimated mean difference and effect size and did not meaningfully change the CIs, indicating the main results are robust to these potential confounders, and the full results are reported in Multimedia Appendix 1.

Primary Outcomes

Uptake of Aerobic PA Guidelines

We used the more rigorous measure of aerobic PA (ie, purposeful aerobic PA which did not include everyday activities, eg, housework, gardening, etc) to gauge the uptake of aerobic PA guidelines via the provided aerobic PA programs. For changes in broader measures of aerobic PA, see Table 3. At baseline, 44% (24/55) of participants met the purposeful aerobic PA guidelines (150 min of moderate or 90 min of vigorous) aerobic PA per week. At postintervention, this figure increased by 11% to 55% (30/55) participants meeting purposeful aerobic PA guidelines (Table 4). Of those participants who did not meet full purposeful aerobic guidelines at baseline, at postintervention, 37% (11/52) of participants met these guidelines (P=.06; Table 5).

XSL•FO

Yes	0 (0)	2 (100)	2 (100)

Uptake of Full PA Guidelines

Meeting the full PA guidelines includes aerobic PA as described above, as well as 2 or more strength sessions per week, and for older adults, balance exercises as often as possible (at least once per week). At baseline, 52 of 55 (94%) participants were not meeting the full purposeful PA guidelines, and postintervention, this figure had dropped to just over half (28/55) of participants who were not meeting these guidelines (Table 4). Likewise, of those participants who did not meet full purposeful total guidelines at baseline, 44% (22/52) of participants met these guidelines at postintervention (P<.001; Table 5).

Secondary Outcomes

Acceptability, Feasibility, and Safety

Postintervention feedback was received from 94% (49/52) of intervention completers. Further, 51 of 52 (98%) participants found the program to be useful, and all 52 participants stated they would recommend such a program to a friend, demonstrating acceptability. At week 12, a total of 96% (50/52) of participants expressed an intention to continue with PA beyond the EXCEL program. Fortnightly catch-up sessions were deemed the most helpful component; all 52 participants rated this support as helpful to very helpful, with 79% (41/52) of participants rating it as very helpful. Catch-up call attendance was very high; 89% (46/52) of participants attended all 6 calls. The remaining 6 participants missed only 1 catch-up session. Most liked that the program was provided online and was completed at home (50/52, 96% of participants, and 48/52, 92% of participants, respectively). Retention rates were notably high; 52 of 55 (95%) participants completed this study, providing support for program feasibility. Zoom technology was used for 91% (189/208) of all catch-up sessions, with telephone a practical back-up option for the remaining 9% (19/208) of sessions. Technology issues were uncommon; 76% (40/52) of participants reported seldom or never encountering problems. The intervention was supported by a comprehensive monitoring system that included 44 email alerts from coaches to the medical team, 35 queries or requests from coaches to the PA team, 3 individual participant sessions via Zoom with an exercise specialist, and several case conferences, ensuring participant safety and supporting adherence.

Dementia Risk Levels

The intervention was associated with a reduction in dementia risk, with an average decrease of 1.52 (SE 0.43) points on the CogDRisk (95% CI 0.65 to 2.39, P=.008; see Table 3). This is consistent with a small to moderate effect (d=0.32, 95% CI 0.13 to 0.50).

Moderate to Vigorous Intensity PA and All PA

Moderate to vigorous intensity PA levels, measured by the CHAMPS, increased by an average of 114.40 (SE 37.39; 95% CI 39.37 to 189.44) minutes per week from baseline to postintervention. The effect size was small to moderate (d=0.32; Table 3). This included any PA performed at moderate or higher intensity, encompassing all types (eg, aerobic or strength-based PA) and any purpose, whether purposeful (undertaken with the intention of being active) or incidental or everyday activity (eg, gardening). Likewise, all PAs increased by an average of 202.25 (SE 54.93; 95% CI 95.02 to 315.48) minutes from baseline to

XSL•FO
RenderX

postintervention; the effect size was small to moderate (d=0.39; Table 3). This included any intensity (low to very high), any type (aerobic, strength, and balance), and any purpose (purposeful and incidental).

PA Guideline Adherence

Weekly adherence data is summarized in Table 6. All component guidelines adherence was highest during weeks 3 to 6 (>70%; at least 36 of the 52 participants), and all component guidelines were met by 31% (16/52) of participants for 8 or more weeks. Average weekly volume of moderate intensity aerobic PA fluctuated over the 12 weeks but did not drop below the recommended 150 minutes per week. Weekly strength session numbers were stable across the intervention and consistently exceeded the minimum of 2 sessions per week, with an average of 2.2 (SD) sessions per week. Weekly adherence to the balance guidelines was only applicable for older adults and was high throughout the intervention. Weekly numbers of balance PA sessions were relatively stable over the 12 weeks, with an average of 4.1 (SD) sessions per week, ranging from 3.8 to 4.3 sessions per week.

Table . Weekly adherence to PA[a] guideline components over the 12-week intervention.

PA component and weekly adherence	Full guideline	≥2/3 guideline
All components[b]		
Highest, n (%)	>36 (>70) – Weeks 3 - 6	41 (79) – Week 4
Lowest, n (%)	20 (39) – Week 12	28 (54) – Week 8
Mean (SD)	23 (44)	34 (65)
Aerobic PA[b]		
Highest, n (%)	33 (64) – Week 3	46 (89) – Week 4
Lowest, n (%)	23 (44) – Week 9	32 (62) – Week 9
Mean (SD)	28 (54)	37 (71)
Strength PA[b]		
Highest, n (%)	≈42 (≈80) – Weeks 1, 3 - 5	≥47 (>90) – Weeks 1, 3 - 5

[c]n=43 (balance component for older adults only).

[d]Not available.

Mental Health Symptoms

Analysis of mental health outcomes measured using the DASS-21 showed improvements across all dimensions. Effect sizes for changes in depression, anxiety, and stress scores were large at 1.31, 0.89, and 1.18, respectively (Table 3). Depression decreased by 6.1 points (SE 0.7; 95% CI 4.7 to 7.4; P<.001), anxiety decreased by 3.2 points (SE 0.5; 95% CI 2.1 to 4.2; P<.001), and stress decreased by 6.5 points (SE 0.8; 95% CI 4.8 to 8.2; P<.001). DASS-21 subscale scores can be multiplied by 2 to allow comparison with established DASS-42 severity norms. Using this interpretive framework, mean depression and stress scores shifted from the severe to mild range, and anxiety scores from the moderate to normal range.

Exercise-Related Cognitive Mechanisms (Change Readiness, Self-Efficacy, Outcome Expectations, Benefits and Barriers, and Planning)

There was strong evidence of an intervention effect on change readiness (χ^2_4=16.1, P<.003). As shown in Table 7, a total of 27 of 52 (52%) participants transitioned from a lower stage at baseline of change to a higher stage of change at postintervention, and 29 of 52 (56%) participants remained in the same stage of change at postintervention. For the latter group, however, there was a ceiling effect whereby 15 of the 29 participants who started in the highest stage of change at baseline could not transition to a higher stage of change at postintervention. Notably, all participants who started in stage 2 or stage 3 at baseline progressed to a later stage of change postintervention. There were 8 of 52 (15%) of participants who transitioned from a higher stage of change at baseline to a lower stage of change post intervention.

XSL•FO
RenderX

Table . Stages of change transition from baseline to postintervention (n=52).

Baseline	Postintervention					
	1	2	3	4	5	Total
Do not intend, n (%)	0 (0)	0 (0)	0 (0)	1 (100)	0 (0)	1 (100)
Intend to start, n (%)	0 (0)	0 (0)	1 (14)	6 (86)	0 (0)	8 (100)
Started but not regular, n (%)	0 (0)	0 (0)	0 (0)	13 (77)	4 (24)	17 (100)
Have started regular, n (%)	0 (0)	0 (0)	2 (33)	1 (17)	3 (50)	6 (100)
Currently exercise regularly, n (%)	1 (5)	1 (5)	0 (0)	4 (19)	15 (71)	21 (100)

There were no significant changes in self-efficacy or perceived barriers and benefits to exercise (Table 3). However, our data demonstrated an improvement in both planning and positive outcome expectation postintervention. There was a moderate effect of the intervention for average planning (*d*=0.66, 95% CI 0.34 to 0.99), with an average increase of 1.07 points (SE 0.24; 95% CI 0.58 to 1.56, *P*=.001) from baseline to postintervention. Furthermore, there was a small to moderate intervention effect on positive outcome expectations for exercise (*d*=0.33, 95% CI 0.11 to 0.54), with an average increase of 0.20 points (SE 0.06; 95% CI 0.07 to 0.33, *P*=.02).

DRR Cognitive Mechanisms (Dementia Knowledge and Motivation)

There was no change in dementia knowledge (mean difference=0.09, SE 0.5; 95% CI −0.20 to 0.02, *P*=.47) and attitudes and beliefs toward lifestyle adaptations for DRR (mean difference=0.05, SD, 95% CI –0.03 to 0.13, *P*=.92) from baseline to postintervention (Table 3).

Discussion

Principal Findings

These findings support our hypothesis that the EXCEL program, a 12-week digitally delivered, tailored PA intervention, could effectively facilitate middle-aged and older Australians experiencing mild to moderate mental health symptoms alongside cognitive concerns to meet PA guidelines. The program was acceptable, feasible, and safe and was associated with reductions in both dementia risk and mental health symptoms and progression through stages of change. Changes to action planning and positive outcome expectancies were observed and present potential mechanisms of action, reflecting components of the behavior change model that informed the intervention's design [14]. Given the well-documented challenges in engaging this population in sustained PA and the critical importance of PA for DRR, these results are particularly encouraging.

Comparison With Prior Work

EXCEL was highly efficacious; nearly half of the cohort (24/55, 44% participants) met PA guidelines at the end of the program, up from 6% (3/55) of participants at baseline. The increases in PA are particularly encouraging given the low proportion meeting PA guidelines at baseline (<6%), compared to the Australian population levels of 22.4% of adults and 33.4% of older adults [56]. Low baseline PA levels in our cohort fit with evidence that people with mental health disorders are significantly less likely to meet PA guidelines compared to controls [57]. This further underlines the critical importance of interventions that are tailored to support this cohort at high risk for dementia. Retention rates (95%) and positive feedback from participants (ie, 98% found it useful and 100% would recommend it to others) demonstrate that the program was well-received. High levels of acceptability might be attributed to the individually tailored nature of the intervention, which was designed based on comprehensive formative research incorporating the preferences and needs of the target demographic [15]. It is also relevant to note that EXCEL was conducted in part during the COVID-19 lockdowns, which may have increased participants' involvement due to a reduction in alternative activities and distractions. Evidence suggests that while COVID-19 had a mixed impact on research participation, research that used PA was associated with increased involvement [58].

Safety was a central focus of our design, particularly given the online delivery. While the safety, scalability, and effectiveness of digital PA interventions have been well documented in younger adults (see umbrella review by Russell et al [59]), there remains a gap in the literature regarding older adults. We used a robust system of support and monitoring that included email alerts and professional consultations that managed physical and mental health risk successfully. Our current results, taken together with data that show the majority of middle-aged and older adults are online (98% of Australians aged 65 - 74 y and 94% of those aged 75 y + [60]), suggest that age should not be seen as a barrier to accessing safe and effective online PA interventions. Another advantage suggesting future scalability was that coaches were not required to have mental health credentials or exercise physiology expertise themselves to be highly effective. The safety of our trial and the training and support of our coaches did, however, require qualified mental health and exercise physiology clinicians in an oversight capacity, which has implications for real-world implementation.

XSL•FO
RenderX

A significant reduction in dementia risk was observed over the 12 weeks, as measured by the CogDRisk, a validated online measure that assesses individualized risk factors of dementia in various population settings [42,61]. These results support a developing literature showing that PA reduces dementia risk in other high-risk groups, including those with new-onset type II diabetes [62]. Baseline dementia knowledge in our cohort was low and was not modified by our intervention, which is to be expected given that this was not an aim of the current study. This does demonstrate, however, that it is not essential to increase dementia knowledge to reduce dementia risk, which may be particularly pertinent for individuals with cognitive difficulties. Nonetheless, integrating additional psychological or social support structure components could further enhance the intervention's impact on self-efficacy and sustained behavior change.

We evaluated whether the intervention impacted mental health symptoms and found a significant and clinically meaningful improvement across all DASS-21 dimensions. After 12 weeks, our cohort's anxiety levels had returned to within the normal range, while depression and stress symptoms were now mild. This is a meaningful change from the extremely severe (stress), severe (depression), and moderate (anxiety) average symptom scores observed 12 weeks earlier, at baseline. Our findings add to the established literature showing the important positive effect that exercise can play in improving mood; a finding reflected in clinical practice guidelines in the United States, United Kingdom, and Australia [63-65]. A recent meta-analysis by Noetel et al [66] showed exercise to be equally effective for people with and without comorbidities, and with different baseline levels of depression. Their findings reflected over 200 studies [66] and suggest that walking and strength training are among the most effective exercises for depression reduction, in line with PA guidelines that underlie EXCEL. While evidence for the anxiety-reducing effect of PA is currently less consistent (see Chong et al [67] for a meta-analysis), we were encouraged to see that PA reduced anxiety levels in our cohort.

Potential Mechanisms of Action

EXCEL was designed to specifically target proposed mechanisms of action for optimizing engagement in this cohort, including emotional regulation, self-efficacy in existing skills, and the capacities to act on intentions despite barriers, and we measured these potential cognitive mechanisms pre- and postintervention. Our findings showed a small to moderate, but significant, increase in positive outcome expectations for exercise. Positive outcome expectancy refers to an individual's belief that PA will lead to certain (positive) outcomes and is 1 of 2 key constructs in social cognitive theory, alongside self-efficacy. Our findings are consistent with previous research showing that (1) positive, rather than negative, outcome expectancy is associated with PA levels, and (2) there is an apparent age-related effect whereby outcome expectancy is more predictive of PA in older adults [68]. Positive outcome expectancies have previously been observed to facilitate the formation of PA intentions [68] and are associated with progression through the stages of change, as seen in this study. Considered within the COM-B framework, positive outcome expectancies may enhance motivation and support the development of strong intentions to engage in PA.

However, transitioning from intention to behavior often relies on effective action planning—that is, setting concrete, detailed plans that outline the when, where, and how of intended PAs [69]. Our findings support this notion. The mental stimulations involved in planning have also been shown to have a self-regulatory effect that may help individuals connect their behavioral responses to future scenarios and account for potential barriers [70]. In this context, our intervention may have supported participants in mentally rehearsing the steps needed to translate PA intentions into action, reducing the intention-behavior gap. This aligns with our findings on the stages of change measure: at baseline, participants primarily scored in the "preparation" stage, characterized by intentions to begin regular exercise or making sporadic attempts to be active. Following the intervention, averages shifted to the "action" stage, reflecting active and consistent engagement in structured exercise. These results suggest that aging adults with cognitive difficulties related to subjective or MCI and co-occurring mental health symptoms may particularly benefit from pragmatic, structured action planning that bridges the gap between intention and behavior.

Limitations and Future Directions

While our results are promising, they should be interpreted with caution due to the pilot nature of this study, modest sample size, and pre-post design. This study's design prevented a valid causal mediation analysis, meaning that changes in hypothesized mediators can only be described rather than inferred as causal. Further research using a larger sample and a randomized controlled trial design with mediation analyses is needed to determine whether the proposed mechanisms contribute causally to the observed outcomes. Sensitivity analyses indicated that age, gender, baseline depression score, and overall minutes of PA did not confound the findings. However, technological or digital literacy was not measured, and engagement may have been higher during COVID-19 lockdowns; these unmeasured confounders may limit generalizability to nonpandemic conditions. Despite these limitations, the findings exemplify the utility of tailored interventions and the value of a behavior-change framework. It is recommended that future studies include larger cohorts and longer follow-up periods to replicate findings and evaluate the durability of effects. Given the complexity of factors influencing PA adherence and mental health among aging adults, multicomponent interventions that address both physical and cognitive health holistically are recommended.

Conclusions

This pilot study demonstrated EXCEL to be effective, acceptable, feasible, and safe. The tailored, PA-delivered PA intervention supported middle-aged and older adults experiencing mild to moderate mental health symptoms alongside cognitive concerns to meet PA guidelines. Important secondary gains were a reduction of dementia risk and clinically meaningful improvements in mental health symptoms, emphasizing the advantages of boosting PA in high-risk groups. Improvements in action planning and outcome expectancy may

XSL•FO
RenderX

have contributed to bridging the PA intention-behavior gap, in line with the COM-B model underlying the intervention design. While findings require confirmation in larger controlled trials, the results suggest that EXCEL offers a scalable, evidence-informed model for supporting dementia-risk reduction in adults who face well-documented barriers to engaging in sustained PA.

Acknowledgments

The authors would like to thank this study's participants of both phase 1 and phase 2 of the EXCEL study, Dr Francine Moss and Dr Brett Coulson for their contributions to earlier versions of the EXCEL design and the StepUp for Dementia Research service for their assistance with participant recruitment. Study data were collected and managed using REDCap (Research Electronic Data Capture) tools hosted at The University of Melbourne. Abstract

Background: Age-related declines in metabolic, cardiovascular, and physical function contribute to reduced quality of life in older adults. Although structured exercise is central to healthy aging, the optimal modality remains unclear. Community-based exercise programs in China are heterogeneous, and their comparative effects on health outcomes and cardiovascular safety have not been systematically evaluated.

Objective: We aimed to compare the effects of 4 common community-based exercise modalities on cardiometabolic health, physical function, and quality of life in middle-aged and older adults, and to assess their relative efficacy and safety across intervention exposure.

Methods: This single-blind randomized controlled trial included 113 middle-aged and older adults (mean age 62.3, SD 4.25 years). Participants were assigned to one of the 5 groups: 12-form Chen-style Tai Chi (CTC12), 24-form Tai Chi, square dance, walking, or a control group. The 12-week intervention comprised 2 supervised sessions per week, each lasting 90 minutes. Pre- and postintervention assessments included blood pressure, lipid profiles, fasting glucose, interleukin-6 levels, Short Physical Performance Battery (SPPB) scores, activities of daily living, and the World Health Organization Quality of Life (WHOQOL) index.

Results: The CTC12 and square dance groups showed significant improvements in several outcomes. In the CTC12 group, triglyceride and low-density lipoprotein cholesterol levels significantly decreased (P=.008 and P=.002, respectively), whereas SPPB and WHOQOL scores significantly improved (P=.02 and P=.002, respectively). In the square dance group, total cholesterol, triglyceride, and low-density lipoprotein cholesterol levels significantly decreased (P=.01, P=.002, and P=.002, respectively), whereas SPPB, activities of daily living, and WHOQOL scores significantly improved (P=.04, P=.04, and P=.002, respectively). The walking group showed a significant improvement only in WHOQOL scores (P=.02). No significant changes were observed in the control group for any outcome.

Conclusions: CTC12 and square dance were associated with significant improvements in cardiometabolic, physical, and psychological health outcomes in middle-aged and older adults. CTC12 demonstrated broader multidimensional benefits, potentially reflecting the integration of physical, respiratory, and cognitive components. These modalities may represent safe and scalable strategies for promoting healthy aging in community settings.

KEYWORDS

Tai Chi; cardiometabolic health; functional rehabilitation; community-dwelling population; middle-aged and older adults

Introduction

The global population is aging at an unprecedented rate, with the number of individuals aged >65 years worldwide projected to increase from 703 million in 2019 to 1.5 billion by 2050 [1,2]. As life expectancy rises, older adults are increasingly susceptible to chronic conditions and their associated health burdens [3], a shift that has contributed to higher rates of chronic disease, poor health status, and functional decline among middle-aged and older populations [4,5]. Multimorbidity further compounds this burden, affecting approximately 46% of older adults worldwide [6-8], thereby underscoring the need to prioritize preventive strategies. Among these, exercise remains a key nonpharmacological intervention with well-established benefits for cardiometabolic health in aging populations [9,10].

Advancing age is associated with an increased risk of cardiovascular diseases, including hypertension and hyperlipidemia, as well as metabolic disorders, such as metabolic syndrome and diabetes mellitus (DM) [11,12]. Hypertension, affecting approximately 30% of the population and disproportionately prevalent in older adults, is a major contributor to global mortality [13-15]. Elevated systolic blood pressure (SBP) and diastolic blood pressure (DBP) are well-established predictors of cardiovascular disease and all-cause mortality [16], while pulse pressure (PP), reflecting the interplay between SBP and DBP, has gained recognition as an important indicator of vascular aging and mortality risk [17]. Dyslipidemia—characterized by elevated total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C), alongside reduced high-density lipoprotein cholesterol (HDL-C)—is likewise strongly associated with adverse outcomes in older populations [18]. Additionally, composite indices integrating glucose and lipid metabolism, including fasting plasma glucose (FPG) and the triglyceride/HDL-C ratio, have emerged as important predictors of cardiometabolic risk [19].

DM, a chronic metabolic noncommunicable disease characterized by persistent hyperglycemia, remains a significant contributor to global mortality [20-22], with diagnosis defined by FPG levels≥7.0 mmol/L (126 mg/dL) [23]. In 2015, approximately 415 million adults aged 20-79 years had diabetes, and this number is projected to increase by an additional 200 million by 2040 [20], placing a growing strain on health care systems worldwide, particularly among older populations [12]. In parallel, age-related chronic low-grade inflammation, commonly termed “inflammaging” [24], is characterized by maintained elevations in proinflammatory markers, such as interleukin-6 (IL-6), and is closely linked to cardiovascular disease, diabetes, and metabolic syndrome [25,26]. Accordingly, IL-6 was used in this study as a biomarker to capture the systemic physiological effects of exercise. Beyond physical health, older adults face an increased risk of mental health challenges [27,28], necessitating a comprehensive evaluation of both functional and psychological domains. Thus, we used validated instruments, including the Short Physical Performance Battery (SPPB), activities of daily living (ADLs), and the World Health Organization Quality of Life (WHOQOL) index to assess multidimensional outcomes [29-31]. Midlife represents a critical period during which risk factors for functional decline emerge, while also offering substantial potential for recovery [32]. Thus, we focused on middle-aged and older adults to examine the role of exercise in disease prevention and functional rehabilitation.

Tai Chi, originating from traditional Chinese medicine and guided by movement-based theoretical frameworks, integrates principles, such as yin-yang philosophy and meridian theory [33]. It has evolved into a comprehensive practice promoting both physical and psychological well-being. Empirical evidence indicates that Tai Chi confers benefits across a range of conditions, including hypertension, hyperlipidemia, DM, metabolic syndrome, inflammation, impaired physical function, limitations in ADLs, and psychological disorders [34-36]. However, most interventions have relied on the simplified 24-form Tai Chi (TC24), derived from Yang-style Tai Chi [37], which emphasizes slow, low-intensity movements and simplified structures that facilitate safety and widespread dissemination.

Despite these advantages, its low intensity and repetitive movements may limit energy expenditure and neuromuscular engagement, potentially constraining its effectiveness in improving cardiometabolic health and higher-level physical function [38,39].

These limitations highlight the necessity for more dynamic and integrative exercise modalities [40]. Chen-style Tai Chi incorporates both slow, controlled movements and rapid, forceful actions, including stomping and explosive movements, thereby enhancing neuromuscular activation and energy metabolism while maintaining safety and fluidity of motion [41,42]. The 12-form Chen-style Tai Chi (CTC12) preserves the core elements of traditional Chen-style practice while integrating 12-meridian regulation theory from traditional Chinese exercise, resulting in a rhythmically diverse and functionally comprehensive intervention. CTC12 is hypothesized to provide greater benefits than TC24 in improving neuromuscular function, metabolic regulation, and multidimensional health outcomes in middle-aged and older adults [43].

In parallel, square dance represents a widely adopted form of aerobic exercise among middle-aged and older populations, offering both physical and psychosocial benefits in community settings [44]. Similarly, walking, another accessible and low-risk group-based activity, has gained popularity. Both modalities

XSL•FO
RenderX

are associated with lower cardiovascular demands and risk of injury, and have been proven efficient in improving blood pressure, lipid metabolism, glucose regulation, and psychological well-being, including reductions in symptoms of depression and anxiety [33,45].

Despite evidence supporting the benefits of Tai Chi and aerobic exercise for cardiovascular and metabolic health among older adults, several gaps remain. First, most studies have focused on TC24, with limited investigation of more dynamic forms, such as Chen-style Tai Chi, and variability in intervention characteristics—including duration, intensity, and form—has contributed to heterogeneity in reported outcomes, underscoring the need for more standardized approaches [46]. Second, previous research has often examined single health outcomes, with limited evaluation of multidimensional physiological effects, particularly inflammatory markers [47]. Third, comparative studies of community-based aerobic activities, including Tai Chi, square dance, and walking, remain limited, and direct comparisons with structured mind-body interventions are scarce. Addressing these gaps requires comprehensive, well-designed randomized controlled trials [48,49].

Accordingly, this study was conducted to systematically evaluate the effects of CTC12, TC24, square dance, and walking on cardiometabolic, functional, and psychological outcomes in community-dwelling middle-aged and older adults, while assessing the safety and dose-related efficacy of each modality. Moreover, the study sought to provide evidence to inform the development of safe, effective, and sustainable individualized exercise strategies for aging populations.

Methods

Participants

In this study, we enrolled community-dwelling middle-aged and older adults who were capable of participating in physical exercise. Participants were recruited from local community centers and health clinics. Of 155 individuals screened, 120 were enrolled (mean age 63.0, SD 4.5 years; 97/120, 80.8% female). Eligibility criteria included age 50-70 years, absence of clinically diagnosed cardiovascular, musculoskeletal, metabolic, or cognitive disorders, and no regular participation in structured exercise within the preceding 6 months (defined as <1 session/week). Exclusion criteria comprised current use of medications affecting blood pressure, lipid metabolism, or glucose regulation (eg, antihypertensive agents, statins, or antidiabetic drugs), as well as current smoking or smoking cessation within the past 6 months.

Study Design

This study was a single-blind randomized controlled trial conducted among community-dwelling middle-aged and older adults. Following baseline assessments, participants were randomly assigned in a 1:1:1:1:1 ratio to one of the 5 groups—CTC12, TC24, square dance, walking, or a control group. Randomization was performed using a computer-generated sequence prepared by an independent researcher, with allocation concealed in sequentially numbered, opaque, sealed envelopes, which were opened after baseline assessments. Outcome assessors and laboratory personnel were blinded to group allocation, and participants were informed only of their assigned intervention. Each participant received a unique identification code, and all assessments were conducted according to standardized procedures by trained evaluators. No sex-based restrictions were applied, and all interventions and assessments were implemented uniformly across sexes. Before the intervention, participants completed a 1-week familiarization period to facilitate adaptation, enhance adherence, and ensure correct execution of the assigned exercises.

Ethical Considerations

The study protocol was approved by the Ethics Committee of Beijing Fengtai Hospital (approval P2024022) and complied with the Declaration of Helsinki. All participants provided written informed consent after receiving detailed information regarding study objectives, procedures, potential risks, and participant rights. Assessments were conducted by licensed medical professionals from Beijing Fengtai Hospital and Nankang District Hospital of Traditional Chinese Medicine (Ganzhou, Jiangxi Province). Adverse events were evaluated and managed on-site. Personal data were anonymized and coded to ensure confidentiality and were used exclusively for research purposes.

After completing the study, participants were provided with full electronic instructional videos for CTC12, TC24, and square dancing.

Intervention Protocol

Participants in each intervention group attended supervised sessions twice weekly for 90 minutes over a 12-week period, conducted from 8 to 9:30 AM. The interventions were defined as follows: (1) CTC12, which emphasized explosive techniques (fa jin), jumps, and complex transitions to enhance neuromuscular coordination and cardiopulmonary function; (2) TC24, a standardized and simplified form of Yang-style Tai Chi, focusing on breathing rhythm, flexibility, and balance [37]; (3) square dance, a moderate-to-high intensity aerobic dance performed at 60%-75% of maximum heart rate (HR) [50]; (4) walking, performed as brisk walking at 3.5-4.0 km/h on flat terrain, targeting 50%-60% of maximum HR, and monitored using HR devices [50,51]; and (5) control, continued daily activities with no additional structured exercise.

All sessions were conducted outdoors under temperatures ranging from 24 °C to 28 °C. Although humidity and air circulation were not controlled, participant safety and comfort were ensured throughout. Each session began with a standardized 10-minute warm-up consisting of light aerobic activity and joint mobility exercises. Tai Chi interventions (CTC12 and TC24) were led by Shaoqing Zeng, with more than 10 years of teaching experience and recognized competitive achievements at the city level. Square dance and walking interventions were designed and supervised by WS, with a doctoral degree in Sports Science and extensive experience in physical education and exercise interventions, who had participated in the design and implementation of several community-based exercise programs (Multimedia Appendix 1).

XSL•FO
RenderX

Outcome Measures

Primary Outcomes

Fasting venous blood samples were collected between 7 AM and 9 AM before and after the 12-week intervention, following ≥10 hours of fasting, and were processed within 2 hours. Blood pressure was measured twice in a seated position using an automated sphygmomanometer (Omron HEM-7320 [Omron Healthcare]), and PP was calculated as SBP−DBP [52]. Lipid profiles, including TC, triglycerides, HDL-C, and LDL-C, were measured using enzymatic colorimetric assays (Cobas c 501 [Roche]) [52,53]. FPG was measured using the glucose oxidase method (LabX) [54]. Serum IL-6 concentrations were quantified using a high-sensitivity ELISA kit (Human IL-6 Quantikine HS ELISA [R&D Systems]; catalog HS600C) [55], with a detection limit of 0.09 pg/mL. According to the manufacturer's specifications, the intra-assay coefficient of variation ranged from 3.6% to 4.7% and interassay coefficient of variation from 3.9% to 10.8% across 3 concentration levels. Serum samples were aliquoted and stored at −80 °C until analysis [56]. Samples were assayed in duplicate, and the mean of the 2 measurements was used for analysis. The assay detection limit was 0.09 pg/mL. Laboratory technicians were blinded to group allocation, and all samples were analyzed in a single batch to minimize variability.

Basal metabolic rate (BMR) was estimated using bioelectrical impedance analysis (InBody H30NWi [InBody Co]) [57]. HR data, including resting HR and average exercise HR, were recorded using photoplethysmography-based monitors (Polar H10 [Polar Electro]) [58]. The change in heart rate (ΔHR) was defined as the difference between average exercise HR and resting HR during each 90-minute session. Energy expenditure (kcal), including calories at rest and additional calories expended during exercise sessions, was estimated from continuous HR monitoring (Polar H10) [59].

Physical function was assessed using the SPPB (score range 0-12), which includes static balance, 4-meter gait speed, and the 5-time chair stand test [60]. Functional independence was evaluated using ADLs, measured as the ability to perform basic daily activities [61]. WHOQOL was assessed using total scores across 6 domains from the WHOQOL-100 instrument [62].

Secondary Outcomes

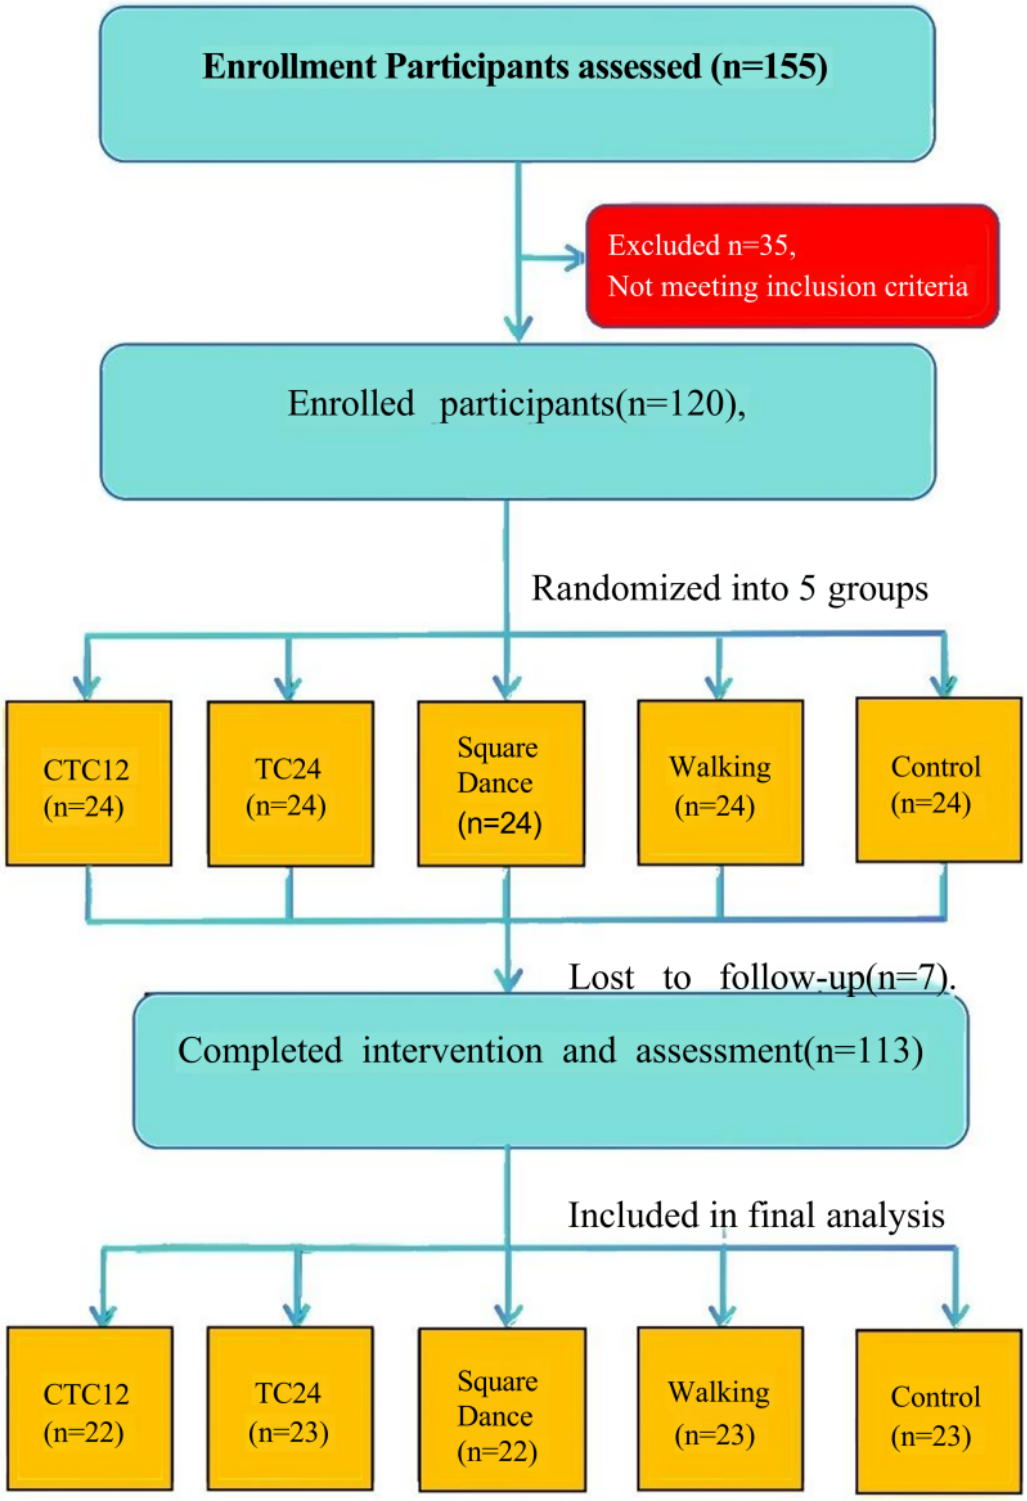
Secondary outcomes included the six WHOQOL domain scores: (1) Q1: physical health, (2) Q2: psychological health, (3) Q3: social relationships, (4) Q4: environment, (5) Q5: self-perceived health, and (6) Q6: self-rated overall quality of life [62,63]. All evaluations were conducted by trained personnel blinded to group assignment.

Sample Size Estimation

An a priori power analysis was performed using G*Power (version 3.1.9.7) for a mixed repeated-measures ANOVA (within-between interaction; group×time interaction). The SPPB was selected as the primary outcome, reflecting the central role of physical function in this study. The expected effect size was set at η^2=0.065 based on previous literature [64], corresponding to Cohen $f=\sqrt{(\eta^2/(1-\eta^2))}$=0.264. Assuming α=.05, power (1−β)=0.95, 5 groups, 2 measurements (pre- and postintervention), correlation among repeated measures of 0.50, and ε=1, the required sample size was 75 participants (15 per group). To account for an anticipated attrition rate of 20%, a minimum of 94 participants (required final sample size=75, expected retention rate=0.80) were targeted (Multimedia Appendix 2).

Statistical Analysis

All statistical analyses were performed using R (version 4.2.1; R Core Team). Continuous variables are presented as mean (SD). Within-group comparisons were assessed using paired *t* tests, and between-group comparisons were conducted using 1-way ANOVA with Tukey post hoc tests. Normality and homogeneity of variance were evaluated using the Shapiro-Wilk and Levene tests, respectively. To address potential inflation of type I error due to multiple comparisons across outcomes (eg, blood pressure, fasting glucose, lipids, IL-6, SPPB, and WHOQOL subdomains), the false discovery rate correction was applied. All tests were 2-tailed, with statistical significance defined as $P<.05$. Adjusted *P* values, effect sizes, and 95% CIs were reported to complement dichotomous significance testing.



Results

Participant Flow and Baseline Characteristics

As illustrated in the CONSORT (Consolidated Standards of Reporting Trials) diagram, 155 individuals were screened, of whom 120 (77.4%) eligible community-dwelling middle-aged and older adults were enrolled. During the 12-week intervention, 7 participants withdrew due to personal reasons or insufficient attendance (<90%) and were subsequently classified as dropouts. Ultimately, 113 participants completed the intervention and all assessments. The final group sizes were as follows: (1) CTC12: n=22, (2) TC24: n=23, (3) square dance: n=22, (4) walking: n=23, and (5) control: n=23 (Figure 1, Table 1).

Primary Outcomes

Within-Group Comparisons

No significant changes were observed in DBP, SBP, and PP across all groups (all *P*>.05). Regarding lipid profiles, TC significantly decreased only in the square dance group (*P*=.01). Triglyceride and LDL-C significantly decreased in both the CTC12 (*P*=.008 and *P*=.002, respectively) and square dance (*P*=.002 for both) groups. HDL-C remained unchanged in all groups (all *P*>.05). In terms of fasting glucose and IL-6, no significant changes were noted in any group (all *P*>.05). For physical function and quality of life, SPPB scores significantly improved in the CTC12 (*P*=.02) and square dance (*P*=.04) groups, whereas ADL scores significantly improved only in the square dance group (*P*=.04). WHOQOL scores significantly improved in the CTC12 (*P*=.002), square dance (*P*=.002), and walking (*P*=.02) groups (Table 2).

[a]CTC12: 12-form Chen-style Tai Chi.

[b]TC24: 24-form simplified Tai Chi.

[c]*F* test: analysis of variance test statistic.

[d]η^{2}: representing effect size.

[e]*P* values represent the significance of overall group differences.

[f]Pairwise comparisons were conducted using Tukey's post hoc tests where appropriate.

[g]DPB: diastolic blood pressure.

[h]Ns: not significant.

[i]SPB: systolic blood pressure.

[j]PP: pulse pressure.

[k]TC: total cholesterol.

[l]TG: triglycerides.

[m]HDL-C: high-density lipoprotein cholesterol.

[n]LDL-C: low-density lipoprotein cholesterol.

[o]IL-6: interleukin-6.

[p]SPPB: Short Physical Performance Battery.

XSL•FO
RenderX

[q]ADL: activity of daily living.

[r]WHOQOL: World Health Organization Quality of Life questionnaire.

[s]BMR: basal metabolic rate.

[t]ΔHR: heart rate increase.

No significant between-group differences were observed for SBP (*P*=.99), DBP (*P*=.82), or PP (*P*=.81).

TC, triglyceride, and LDL-C were significantly lower in the CTC12 (mean 5.03, SD 0.63 mmol/L; mean 1.18, SD 0.60 mmol/L; and mean 2.23, SD 0.70 mmol/L, respectively) and square dance (mean 4.79, SD 1.16 mmol/L; mean 1.27, SD 0.34 mmol/L; and mean 2.18, SD 0.47 mmol/L, respectively) groups than in the control group (mean 5.79, SD 0.90 mmol/L; mean 1.93, SD 0.68 mmol/L; and mean 2.91, SD 0.77 mmol/L; and *P*=.006, *P*=.001, and *P*=.001, respectively). HDL-C was higher in the CTC12 group (mean 1.53, SD 0.30 mmol/L) than in the control group (mean 1.27, SD 0.19 mmol/L), although this did not reach statistical significance (*P*=.08).

Fasting glucose was significantly lower in the CTC12 and square dance groups than in the control group (*P*=.02), whereas IL-6 did not differ significantly among groups (*P*=.92).

SPPB and WHOQOL scores were significantly higher in the CTC12 and square dance groups than in the control group (*P*=.01 and *P*=.03, respectively), while ADL did not differ between groups (*P*=.12).

BMR, ΔHR, and additional energy expenditure differed significantly among groups (all *P*<.001). BMR was higher in the CTC12 (mean 1391.50, SD 70.78 kcal) and square dance (mean 1396.55, SD 74.45 kcal) groups than in the TC24, walking, and control groups. ΔHR was greatest in the square dance group (mean 46.68, SD 7.48 bpm), followed by the CTC12 group, which showed an increase of mean 29.50 (SD 4.61) bpm, indicating significant differences between groups (*P*<.001).

Additional energy expenditure during 1.5-h sessions was also higher in the square dance (mean 386.65, SD 37.29 kcal) and CTC12 (mean 363.75, SD 18.54 kcal) groups than in the other groups, indicating greater exercise intensity (Table 3; Figure S1 in Multimedia Appendix 3).

Secondary Outcomes: WHOQOL Subdomains

Within-Group Comparisons

Following the intervention, improvements were observed across multiple WHOQOL subdomains. Q1 and Q2 scores significantly improved in all intervention groups (CTC12, square dance, TC24, and walking; all *P*<.05), whereas no significant changes were observed in the control group. In contrast, Q3 improved significantly only in the square dance group (*P*=.003), with no significant changes in the other groups. The environmental quality of life (Q4) remained unchanged across all groups (*P*>.05), although the square dance group showed a borderline decline (*P*=.05). Self-perceived health status (Q5) significantly improved in all intervention groups (*P*<.01). Similarly, self-rated overall quality of life (Q6) increased significantly in all intervention groups (*P*<.01), with no change observed in the control group (Table S1 in Multimedia Appendix 3).

Between-Group Comparisons

Postintervention comparisons showed varying patterns across subdomains. Q1 scores were highest in the square dance group and lowest in the control group, with a marginal group effect (*P*=.06). Q2 scores were significantly higher in the CTC12 and square dance groups than in the control group (*P*=.005), indicating improved psychological health. No significant differences were observed for Q3 (*P*=.13), although the square dance group had the highest mean score. Similarly, no significant between-group differences were observed for Q4 (*P*=.78). For Q5, a near-significant group effect was observed (*P*=.09), with higher scores in the CTC12 and square dance groups than in the control group. Q6 did not differ significantly among groups (*P*=.13), although the CTC12 group showed the highest mean overall quality of life score (Table S2 and Figure S2 in Multimedia Appendix 3).

Discussion

Overview of Intervention Effects

This 12-week exercise intervention demonstrated significant benefits in the CTC12 and square dance groups. Both interventions improved lipid profiles, with TC reduced in the square dance group and triglyceride and LDL-C reduced in both the CTC12 and square dance groups, while no significant changes were observed in FPG or IL-6. Functional outcomes also improved, as reflected by increased SPPB scores in both groups and improved ADL scores in the square dance group. WHOQOL scores significantly improved in the CTC12, square dance, and walking groups, indicating enhanced quality of life. Collectively, these findings support the effectiveness of CTC12 and square dance in improving lipid metabolism, physical function, and quality of life in middle-aged and older adults.

Improvements in Cardiometabolic Indicators and Underlying Mechanisms

Regarding blood pressure, although no significant changes were observed in DBP, SBP, or PP across the groups, small trends in blood pressure changes were noted. From a clinical perspective, such small blood pressure changes are unlikely to represent meaningful short-term cardiovascular risk reduction, although minor population-level shifts have been associated with long-term risk trends in epidemiological studies [65]. Mechanistically, CTC12 may influence SBP through coordinated breathing and postural control, potentially modulating autonomic balance and arterial compliance [48]. The square dance intervention, characterized by rhythmic and moderate-to-high intensity movements, may contribute to improvements in large-artery elasticity, which could partly explain the observed PP reduction [66]. Walking, as a low-intensity aerobic activity, may enhance endothelial function and peripheral vasodilation, contributing to modest DBP changes [67]. These mechanisms provide plausible explanations for the observed directional

XSL•FO
RenderX

trends but do not imply clinically significant blood pressure reductions within the intervention period of this study.

The CTC12 and square dance groups demonstrated significant reductions in TC, triglyceride, and LDL-C, while HDL-C was significantly increased in the CTC12 group, indicating beneficial effects on lipid metabolism. The CTC12 regimen, which incorporates strength, coordination, and breathing control, may enhance lipid homeostasis and contribute to increases in HDL-C [68]. In contrast, square dance may improve lipid profiles through enhanced lipoprotein lipase activity, facilitating very-low-density lipoprotein clearance and cholesterol transport [68]. Although the CTC12 group exhibited greater increases in HDL-C, and the square dance group showed more pronounced reductions in TC, both groups demonstrated complementary effects on lipid regulation, which may have beneficial implications for cardiovascular prevention [69]. The square dance group exhibited a more pronounced reduction in TC, whereas the CTC12 group was more effective in elevating HDL-C, indicating distinct yet complementary lipid-regulatory mechanisms. Both groups achieved clinically relevant lipid thresholds (eg, triglyceride<1.7 mmol/L and LDL-C<3.4 mmol/L), underscoring their potential role in primary cardiovascular prevention. This suggests that the observed lipid improvements were not only statistically significant but also potentially relevant for practical cardiovascular risk management in community-dwelling older adults [70].

Although not statistically significant, the control group exhibited a worsening trend in TC, triglyceride, and other cardiometabolic markers, which may reflect the absence of structured physical activity [71].

Modulation of Inflammatory Markers

No significant changes in IL-6 levels were observed across intervention groups. This may reflect the relatively healthy baseline status of the participants and the limited duration of the intervention. In such populations, longer intervention periods may be required to detect measurable changes in inflammatory markers. Although mind–body interventions, such as CTC12 and Square Dance, may influence parasympathetic activity and low-grade inflammation, these effects did not translate into detectable changes in IL-6 within the short intervention period. Future studies with extended follow-up are needed to clarify these effects [72].

Improvements in Physical Function and BMR

The CTC12 group demonstrated the greatest improvements in SPPB scores, followed by the square dance group, whereas no significant changes were observed in the walking group. The coordinated activation of core and lower-limb musculature in CTC12 likely contributes to improvements in balance, coordination, and postural control, thereby reducing the risk of falls and improving gait performance. These improvements may be clinically meaningful, as better SPPB performance is closely associated with mobility, reduced fall risk, and preserved functional independence in older adults [73].

Square dance, characterized by rhythmic movement and group participation, was associated with increases in BMR, suggesting enhanced metabolic activity and energy efficiency, which may help delay age-related metabolic decline [74].

Improvements in Quality of Life and Mental Health

WHOQOL scores improved in the CTC12, square dance, and TC24 groups, with the most pronounced improvements in psychological health gains (Q2) observed in the CTC12 and square dance groups. The underlying mechanisms appear distinct. CTC12 may enhance emotional regulation and self-efficacy through long-term cognitive engagement and controlled breathing, facilitating parasympathetic activation [75]. Conversely, the square dance may improve mood, social cohesion, and subjective well-being through social interaction, rhythmic movement, and music [76]. These findings suggest that CTC12 emphasizes internal self-regulation, whereas square dance operates through external social reinforcement, highlighting the importance of tailoring interventions to individual psychological and social profiles [63]. A slight worsening trend in psychological scores was observed in the control group, which may reflect the effects of prolonged inactivity [77].

Safety and Feasibility of the Interventions

Mean exercise HR across all intervention groups remained within 50%-70% of HR_max, consistent with American College of Sports Medicine guidelines for middle-aged and older adults [78]. No falls or cardiovascular events were observed in the CTC12 group, despite the inclusion of explosive movements, likely due to structured warm-up protocols, progressive difficulty, and professional supervision. Similarly, no injuries were reported in the square dance group, despite engaging in moderate-to-high intensity activities. Attendance exceeded 90% across all groups, indicating high adherence and feasibility. These findings support the safety and applicability of these interventions in community-based settings.

Dose-Related Interpretation and Practical Considerations

A descriptive dose-related interpretation was used to examine how differences in exercise intensity and physiological load relate to the breadth of observed health benefits. CTC12 and square dance improved a greater number of outcomes and were therefore compared in terms of exercise dose characteristics and physiological demand. Square dance demonstrated higher energy expenditure (386.7 kcal) and ΔHR (46.7 bpm; approximately 72%-75% HR_max), reflecting moderate-to-high intensity activity. This higher intensity may explain the more rapid improvements in physical function but may also exceed optimal safety thresholds for some older adults, particularly those with cardiovascular risk factors, potentially limiting long-term sustainability. Nevertheless, square dance led to more immediate improvements in physical function, particularly in balance and muscular endurance, possibly due to its higher energy expenditure [79]. CTC12 achieved relatively high energy expenditure (363.8 kcal) and metabolic activation while maintaining a lower cardiovascular load (ΔHR=29.5 bpm; approximately 60%-65% HR_max), consistent with recommended safety ranges for older adults [80]. Although improvements appeared more gradual, CTC12 was associated

XSL•FO
RenderX

with long-term benefits across physical, psychological, and quality-of-life domains with a lower risk of excessive fatigue or cardiovascular strain. These findings suggest distinct practical roles for each intervention. Square dance may be more suitable for individuals seeking higher-intensity activity and faster functional gains, whereas CTC12 may provide a more sustainable, lower-risk option for long-term health maintenance [81-83]. From an implementation perspective, both interventions are feasible in community settings; however, CTC12 may be more appropriate for broader populations due to its moderate intensity and lower cardiovascular demand, whereas square dance may require closer monitoring in higher-risk individuals [84,85].

Limitations

This study has some limitations. The relatively small sample size (n=22 per group) may have limited statistical power, and the 12-week intervention period may not have been adequate to capture long-term effects. Although outcome assessors were blinded to group allocation, participants were necessarily aware of their assigned intervention due to the distinct characteristics of each exercise modality. This awareness may have introduced expectancy-related influences, particularly for self-reported outcomes such as quality of life (eg, WHOQOL). However, such effects are less likely to have substantially influenced objective measures, including blood pressure, biochemical indicators, and physical function. Laboratory personnel responsible for biochemical analyses were blinded to group assignment, which helped mitigate detection bias.

Although the final sample size was adequate for the primary group×time analysis, the study may have been underpowered to detect differences in some secondary outcomes. Accordingly, these findings should be interpreted with caution. In addition, advanced cardiovascular assessments were not included, which limits the ability to characterize underlying physiological changes in greater detail. Future studies should include larger and more diverse samples, extend intervention duration, and incorporate participants at elevated clinical risk. The application of advanced analytical approaches, such as structural equation modeling, may facilitate a more comprehensive understanding of the interrelated metabolic, neural, emotional, and social pathways influenced by exercise. Building on the findings of this study in relatively healthy middle-aged and older adults, further research in populations with cardiovascular disease, metabolic disorders, and other chronic conditions is warranted to clarify clinical benefits and underlying mechanisms across different disease contexts.

Conclusion

In summary, we demonstrated that both CTC12 and square dance were associated with improvements in blood lipid profiles, physical function, and quality of life in middle-aged and older adults. CTC12 was associated with improvements across multiple health indicators, whereas square dance showed more pronounced effects on physical function, metabolic activity, and emotional well-being. In contrast, the effects observed for TC24 and walking were more limited and were confined to selected outcomes. These findings support the role of structured, moderate-to-high-intensity exercise in promoting healthy aging and provide preliminary evidence to inform the development of targeted exercise interventions for age-related health conditions.

Acknowledgments

The authors gratefully acknowledge all participants in this study. We also thank the medical staff of Beijing Fengtai Hospital and Nankang District Hospital of Traditional Chinese Medicine, Ganzhou, Jiangxi Province, for conducting professional pre- and postintervention assessments. Special thanks are extended to Ms Shaoqing Zeng, Ms Xia Wang, and the Nankang District Tai Chi Association for the Elderly in Ganzhou, Jiangxi, for their support in recruiting community-dwelling older adults.

Funding

This study was supported by the research fund of Hanyang University (HY-202400000001631).

Authors' Contributions

JQ conceptualized and designed the study, oversaw intervention procedures, and drafted the manuscript. JW contributed to intervention implementation, clinical data acquisition, and data analysis. XS performed statistical analyses and interpreted the results. WS assisted with data analysis. SMK provided critical input in study conceptualization, design refinement, and data interpretation. All authors reviewed and approved the final manuscript and agreed on the authorship order.

Abstract

Background: Completing home exercise programs remains a significant challenge for older adults after total joint replacement (TJR), often resulting in suboptimal rehabilitation outcomes. Augmented reality (AR) technologies offer a promising approach to addressing limitations associated with traditional paper-based home exercise programs.

Objective: This study aimed to identify priorities for design features and practical or logistical considerations to inform the future design of a 3D AR system (3D ARS) to support home-based rehabilitation for older adults following TJR.

Methods: A cross-sectional online survey was administered via Qualtrics. The survey included items across four domains: sociodemographic and clinical characteristics, proposed design features, practical considerations, and logistical details, and potential barriers to access and use of the 3D ARS. Descriptive statistics (frequencies and percentages) were computed, and the Mann-Whitney *U* test was used to examine differences in feature preferences between older adults and service providers.

Results: A total of 145 participants (56 older adults with TJR and 89 service providers) completed the survey (response rate 88.4%). Older adults and service providers shared similar priorities for several design features of the 3D ARS, including embedding individualized exercise programs, providing customized feedback on exercise progress, and including background music during exercise (all $P>.05$). However, significant differences emerged for other features. Older adults ranked the ability to receive positive, encouraging messages during exercises ($U=1525$, $P<.001$), voice activation prompts ($U=1145$, $P<.001$), and the ability to pause and resume exercises at any time ($U=1843.50$, $P=.01$) as higher priorities than service providers. Most older adults preferred real-time visual prompts to guide joint range of motion during exercise (42/56, 75%), whereas most service providers preferred chart-based progress reports (63/89, 71%). Participants further recommended accessing the system through physiotherapy clinics, initiating use within the first month following surgery, and maintaining access for 6 - 12 months.

Conclusions: Findings identify key user-informed priorities for the design of AR-based rehabilitation technologies for older adults following TJR, including personalized exercise programming, accessible system interfaces, and timely feedback mechanisms. Incorporating these priorities into future system development may support scalable models of home-based rehabilitation that complement conventional physiotherapy care.

Introduction

Total joint replacement (TJR) is a well-established surgical intervention for older adults with advanced osteoarthritis when conservative management strategies are no longer effective [1]. Advances in surgical techniques, perioperative care, and enhanced recovery pathways have shortened hospital stays, and most patients (74% - 96%) are now discharged directly home after surgery [2-4]. After discharge, patients are typically prescribed home exercise programs to restore joint range of motion, muscular strength, and functional mobility [5]. However, maintaining adherence to home exercise programs remains challenging for many older adults after TJR, often resulting in delayed functional recovery and reduced quality of life [6,7]. Commonly reported barriers include limited access to supervision and feedback once patients return home [8,9],

XSL•FO
RenderX

difficulties recalling or correctly performing prescribed exercises [10], low motivation [11,12], and challenges integrating structured exercise into daily routines [9,11]. Additional contextual factors, such as variability in home environments [13,14], limited social support [15], and geographic or transportation barriers to outpatient physiotherapy services [16], may further constrain engagement in rehabilitation for some older adults after TJR. Conventional paper-based home exercise programs, while inexpensive and widely used, often provide static instructions that lack personalization, interactivity, and real-time performance feedback, which may further limit motivation and adherence [17,18].

Emerging augmented reality (AR) technologies present a promising avenue for addressing some of these challenges. AR systems overlay virtual images and information onto the real-world environment, allowing users to interact with digital content while remaining grounded in their physical surroundings [19,20]. In rehabilitation contexts, AR has been explored as a means of delivering guided exercise, enhancing motor learning through visual and auditory feedback, and supporting task-specific practice within meaningful environments [21-24]. This approach contrasts with fully immersive virtual reality (VR), which replaces the real-world environment entirely and may not be suitable or acceptable for all older adults due to issues, such as disorientation or "cybersickness" and physical discomfort (eg, neck pain) sometimes caused by VR headsets [25,26].

While many contemporary AR applications are delivered using smartphones or head-mounted displays, including optical see-through devices, these platforms may pose usability, cost, and comfort barriers for some older adults, particularly in unsupervised home settings [27,28]. In contrast, AR delivered through familiar nonwearable displays, such as tablets or televisions equipped with cameras, depth sensors, or computer-vision capabilities, may represent a more accessible and acceptable configuration for home-based rehabilitation [21,22,29,30]. In these systems, digital overlays, avatars, or visual cues are superimposed onto a live or screen-based representation of the user's environment, preserving core characteristics of AR while avoiding the need for head-mounted equipment. Although the use of AR glasses as an alternative to the TV or monitor offers a more immersive experience, they can also trigger severe symptoms of visually induced motion sickness and dizziness [31] and might therefore not be suitable for safe use for older adults in a home environment. For older adults, leveraging familiar household devices may reduce cognitive and technical burden, enhance perceived ease of use, and support sustained engagement with rehabilitation technologies [27,32].

One configuration that may support accessible home deployment involves plug-and-play camera-based AR systems that connect directly to household televisions or monitors. Similar systems are already widely used in motion-based gaming. For example, NEX Team Inc (San Jose, CA, USA) offers a small camera-based console (Nex Playground) that connects to a television via HDMI, allowing one to 4 players to interact with virtual games using body movements. Similarly, the MetFutAR Motion Gaming Console (MetaFuture Technologies Inc) connects to televisions via HDMI and uses built-in motion-sensing cameras to track body movements during gameplay. These systems overlay digital elements onto the real-world environment, effectively transforming living rooms into interactive play or activity spaces. Easy installation and relatively low cost are commonly promoted as key advantages of these technologies. These characteristics suggest that similar plug-and-play configurations may offer a practical and scalable platform for delivering AR-supported home-based rehabilitation.

AR systems may enhance the home exercise experience by providing interactive visual cues, gamified tasks, or virtual coaching, thereby increasing engagement and enjoyment. These systems can incorporate motion tracking and sensor-based feedback to provide immediate information on exercise performance, such as identifying errors in joint range of motion or movement quality, capabilities that paper exercise booklets cannot offer [17,33]. AR systems also create opportunities for remote or asynchronous monitoring by clinicians, enabling exercise feedback and progression without requiring frequent in-person visits. By supporting individualized exercise prescription and reducing reliance on in-person visits, AR-enabled home rehabilitation may help address geographic and transportation barriers that can limit access to post-TJR physiotherapy services [34].

Existing rehabilitation research on AR systems includes those targeting improved balance and muscle strengthening, falls prevention, upper limb functionality, and enhanced cognition [35]. Qualitative research has also begun to examine stakeholder perspectives on AR tools designed for home-based use. For example, Fields and colleagues explored the acceptability and appropriateness of an AR home assessment tool, highlighting the importance of user-centered design and stakeholder engagement when developing AR-supported home technologies for older adults [36]. A recent pilot trial of an interactive AR exercise system for knee and hip arthroplasty found that patients and therapists preferred the system over standard paper-based home exercise instructions [17]. Study participants highlighted the system's potential to improve exercise accuracy and adherence to home exercise programs. While AR tools show considerable promise for enhancing TJR rehabilitation, limited engagement of key stakeholders in co-designing, implementing, and evaluating these technologies has hindered their translation into routine rehabilitation care [37,38].

The successful integration of any AR tool into routine rehabilitation care depends on careful alignment with end user needs and real-world clinical workflows [39]. Both older adults and their health care service providers (eg, physiotherapists) are key stakeholders whose perspectives could guide the design of an AR tool to support TJR rehabilitation. Engaging patients and health care service providers can illuminate desirable features, acceptable interfaces, and potential barriers, ensuring that the AR tool is developed to meet users' needs and increases the potential for successful implementation in routine rehabilitation practice. This responds to a gap identified in the ARS literature: that heightened patient understanding of the features and functionality of an AR system is vital to creating beneficial, personalized rehabilitation tools [35].

XSL•FO
RenderX

Therefore, the objective of this study was to identify priorities for design features and practical or logistical considerations to inform the future design of a 3D AR system (3D ARS) to support home-based rehabilitation for older adults following TJR.

Methods

Overview

We began this research program by conducting a qualitative exploration of older adults' perspectives, with particular focus on their pre- and postoperative experiences with TJR [40]. In-depth interviews and focus groups were conducted with 42 older adults with TJR and 4 unrelated family caregivers to explore their everyday use of technology, along with the potential role of AR tools to support home-based rehabilitation post-TJR [19]. Two key themes were identified: (1) dreaming up possibilities related to features, considerations, and logistics that could be incorporated into an ARS, such as providing customized feedback, including motivating messages while performing the exercises, and ensuring timely access to the ARS post-TJR surgery; and (2) being pragmatic about possible barriers to access and use of an ARS system, ranging from cost, confidence, and motivational challenges to concerns about accessing suitable home exercise equipment to maximize recovery while using the ARS [19].

Building on the qualitative findings, the themes informed the development of the survey in this study, which focused on prioritizing system features and outlining practical and logistical considerations to guide the design of a proposed 3D ARS to support home-based exercise programming for older adults after TJR.

As part of the survey development process, an expert-by-experience advisory panel (2 older adults with lived experience and 2 service providers) provided feedback on the survey items. The panel members were sent a draft of the survey and asked to review and complete it independently. After the draft surveys were completed and returned to the research office, a virtual meeting was convened to discuss item clarity, wording, readability, ease of access, and, importantly, overall relevance to older adults. Based on this feedback, revisions were made to refine the wording of survey items and improve clarity. The order of items was also revised based on the feedback to improve readability and flow. The updated survey was subsequently shared with panel members. No additional revisions were suggested at this stage.

Survey participants were recruited through flyers distributed by professional membership organizations (eg, the Canadian Physiotherapy Association, the Canadian Society for Exercise Physiology), organizations that offer support to people with arthritis (eg, the Arthritis Society of Canada), local libraries, seniors' centers, and via emails to participants in our previous research who had consented to be re-contacted for future studies.

The inclusion criteria comprised individuals who self-identified as: (1) an older adult aged ≥65 years with a TJR within the last 6 months—to capture those with relevant post-TJR rehabilitation experience, or (2) a service provider (defined as a health care professional or community service provider with paid or volunteer experience working with older adults with TJR in formal care or community-based settings). All participants were further required to be residents of Canada.

Interested individuals scanned a QR code on the recruitment flyer to access the survey. After an online screening via Qualtrics, interested individuals were provided with detailed information about the study. All individuals were required to provide informed consent before completing the survey online. Each question enabled voluntary responses. Individuals who completed a survey could opt in to receive a $40 CAD (US $30) e-gift card. All survey data were collected using an institutional Qualtrics account (Silver Lake, Seattle, Washington, 2024). The survey took between 30 - 45 minutes to complete.

Data Collection

The survey consisted of 4 sections. Section 1 collected information on general sociodemographic and/or clinical characteristics. Sections 2 to 4 included items derived from our previous qualitative study [40] and were designed to gather information to guide the design and implementation of the 3D ARS.

In Section 2, participants were presented with a list of potential design features and asked to prioritize them for inclusion in the 3D ARS. Participants completed a forced rank-ordering task by dragging and dropping each feature into a ranked list from extremely important (rank=1) to least important (rank=14). Each feature was assigned a unique rank, and ties were not permitted. This approach produces relative, ordinal ranking data rather than independent Likert-type ratings.

Sections 3 and 4 consisted of structured questions with predefined response options using a "select all that apply" format, allowing participants to identify multiple relevant responses. Section 3 asked participants to indicate practical considerations and logistical preferences for the proposed AR system (eg, preferred feedback format, timing of motivational messages, and access pathways). Section 4 presented a list of potential barriers to AR system use and asked participants to select all options that applied to their experience or perspective.

Participants were also provided with a narrative description and a graphic depiction of the proposed 3D ARS, along with a glossary of key terms (eg, AR), to provide context and support informed responses.

Data Analysis

Data were downloaded from Qualtrics and imported into SPSS version 29 (IBM SPSS Statistics) for analysis. Descriptive statistics, including frequencies and percentages, were used to summarize participant characteristics. Items using a "select all that apply" format were also analyzed descriptively using frequencies and percentages.

For survey items involving rankings of desired system features, differences between older adults with TJR and service providers were examined using Mann-Whitney *U* tests. This nonparametric test was selected because the ranking data were ordinal and the 2 groups were independent. Statistical significance was set at $P<.05$.

XSL•FO
RenderX

Since the survey allowed participants to skip individual questions, analyses were conducted using available-case analysis for each item. As a result, the number of responses varies slightly across analyses depending on the number of participants who completed each question.

Ethical Considerations

Ethical approval of the online survey was obtained from the Queen's University Health Sciences and Affiliated Teaching Hospitals Research Board (REH-858 - 23). All participants provided informed e-consent before completing the survey. The survey was anonymous and no identifiable patient-related information was collected. Participants had the right to withdraw from the study by not completing the survey or by contacting the research team after submission to request that their data be withdrawn, without any adverse consequences. All study procedures were in accordance with the relevant guidelines/regulations, including data privacy and the Declaration of Helsinki. Participants who completed the survey and who opted in received a $40 CAD (US $30) e-gift card as a token of appreciation.

Results

Sample Characteristics

Table 1 summarizes the characteristics of the 145 participants who provided demographic information (out of 164 who activated the survey; 88.4% response rate). The sample consisted of 56 older adults with TJR and 89 service providers. Across the sample, most participants were male (68/145, 46.9%). Approximately one-third of the sample lived or worked in Ontario (47/145, 32.4%). Among older adults, left knee replacement was the most reported type of TJR (22/56, 39%). Older adults had a high level of education, with about one-third (22/56, 39%) holding a master's degree. About one-third of the service providers were kinesiologists or exercise specialists (27/89, 30%). Most service providers were practicing in community-based settings (52/89, 58%).

Key Features

The Mann-Whitney *U* test revealed no significant differences between groups in rankings of "capability to embed individualized/tailored recommended exercise options in the 3D ARS" (*U*=2134.50, *Z*=−1.18; *P*=.24), "capability of the 3D ARS to deliver customized feedback on progress with recommended exercises" (*U*=2045, *Z*=−1.60; *P*=.11), or "capability to include background music during exercise" (*U*=2118.50, *Z*=−1.20; *P*=.23). However, older adults and service providers differed in their rankings of "capability of the 3D ARS to deliver positive encouraging messages while performing recommended exercises'" (*U*=1525, *Z*=−3.93; *P*<.001), "capability to activate the 3D ARS using voice activation prompts" (*U*=1145, *Z*=−5.39; *P*<.001), and "ability to pause and resume 3D ARS use at any time" (*U*=1843.50, *Z*=−2.51; *P*=.01). Descriptive statistics for the overall rankings of desired features are presented in Table 2.

Practical Logistics for the 3D ARS

Figure 1 summarizes practical considerations and logistical details for the 3D ARS. When asked how customized feedback should be delivered, most older adults with TJR (42/56, 75%) preferred visual prompts displayed on the 3D ARS screen to help guide and adjust joint range of motion. Conversely, most service providers (63/89, 71%) preferred a chart report of joint range-of-motion exercises displayed on the 3D ARS screen.

Figure 1. Practical considerations and logistical details for using the 3D augmented reality system. HCP: health care professional.

Regarding how encouraging or motivational messages should be delivered, most older adults with TJR (35/56, 63%) and about one-third of service providers (28/89, 31%) preferred motivational messages delivered after every exercise attempt. For tracking and documentation, about one-third of older adults (22/56, 39%) and nearly half of the service providers (40/89, 45%) favored a downloadable or printable table that shows all the data from the exercise start date to the current date.

Regarding where and when end users should obtain access, and who should have data access, most older adults with TJR (43/56, 77%) and service providers (63/89, 71%) recommended that users obtain access to the 3D ARS through a physiotherapy clinic. In terms of timing, over one-third of older adults (21/56, 38%) and nearly half of the service providers (42/89, 47%) indicated that access should begin immediately after surgery or within 4 weeks post-surgery. Nearly half of older adults (24/56, 43%) and more than two-thirds of service providers (60/89, 67%) recommended maintaining access for 6 - 12 months. Additionally, most older adults (40/56, 71%) and service providers (66/89, 74%) recommended that health and social

XSL•FO
RenderX

care providers within the user's circle of care should have access to information generated through the 3D ARS.

Potential Barriers to Access and Usage of the 3D ARS

Table 3 summarizes the potential barriers to access and use of the 3D ARS. As shown in the table, over half of the older adults (31/56, 55%) and service providers (48/89, 54%) reported that cost would be a potential barrier. Nearly half of the older adults (25/56, 45%) and service providers (42/89, 47%) indicated that lack of access to suitable exercise equipment to perform recommended exercises at home would also be a top barrier. Among older adults, additional barriers included a lack of confidence in the 3D ARS setup and use (31/56, 55%) and a lack of motivation to use the 3D ARS (26/56, 46%). Service providers did not identify additional top barriers.

Table . Barriers to access and use of 3D augmented reality system (3D ARS; n=145).

Barriers	Older adult (n=56), n (%)	Service providers (n=89), n (%)
Cost of accessing the 3D ARS	31 (55)	48 (54)
Lack of confidence to set up and use 3D ARS	31 (55)	28 (31)
Lack of motivation to use 3D ARS	26 (46)	20 (23)
Lack of access to appropriate equipment to support exercising at home	25 (45)	42 (47)
Lack of adequate space in residence	21 (38)	30 (34)
Overdependence on 3D ARS for recovery	20 (36)	25 (28)
Inability to complete exercises unsupervised at home	20 (36)	6 (7)
Privacy and safety concerns	15 (27)	33 (37)

Discussion

Principal Findings

This study examined priorities for a 3D ARS to support home-based physical rehabilitation for older adults recovering from TJR. Overall, our findings indicate that older adults were open to the potential use of a 3D ARS to support postoperative rehabilitation in the home. Participants emphasized the importance of individualized exercise programming, timely and meaningful feedback during exercises, and user-friendly system features that support ease of interaction. While older adults and service providers shared several priorities for system design, differences emerged in preferences for certain features, including the format and timing of feedback, motivational messaging, and options that support user autonomy, such as control over on-screen images and virtual environments. Together, these findings highlight key user-informed considerations that can guide the development of AR-based rehabilitation technologies for older adults following TJR.

User Priorities and Personalization in AR-Based Rehabilitation

Older adults and service providers shared several priorities for the design of the 3D ARS, including individualized exercise programs, customized feedback on exercise progress, continuous system availability, and optional features such as background music. At the same time, differences emerged in preferences for certain features, particularly those related to motivational messaging and user autonomy. Participants emphasized the importance of the system's ability to deliver positive encouragement during exercise and to provide options that allow users greater control over on-screen images, virtual environments, and language settings. These findings reflect the heterogeneous needs and recovery experiences of older adults following TJR [41] and underscore the importance of tailoring rehabilitation programming to individuals' functional capacities. Personalization has been widely identified as a core design principle in geriatric rehabilitation technologies, supporting engagement and sustained participation in home-based exercise programs [42].

Real-Time Feedback and the Role of Automated Support in Home-Based Rehabilitation

A key finding was the difference in preferred feedback formats during exercises. Service providers favored simple charts and progress reports, whereas older adults preferred immediate, on-screen visual prompts. This distinction is consistent with previous research showing that therapists often prefer concise, actionable summaries rather than navigating extensive patient metrics generated by digital rehabilitation systems [43]. Prioritizing older adults' perspectives as end users highlights the importance of integrating real-time feedback into AR-based rehabilitation technologies. Although previous studies have demonstrated positive responses to synchronous feedback from remote therapists during exercise sessions [17], the shortage of therapists, logistical challenges of scheduling virtual supervision, and associated health care costs may limit the feasibility of such approaches in routine rehabilitation care [44]. While synchronous supervision may enhance safety for certain clinical populations requiring hands-on support [45], AR-based systems that provide automated feedback may offer a more scalable solution for supporting home-based rehabilitation. Another important finding related to the timing of feedback was that participants preferred motivational messages to be delivered after each exercise attempt. This finding aligns with existing evidence suggesting that frequent positive feedback can reinforce desired behaviors and improve exercise adherence [46]. This finding emphasizes the need to incorporate multimodal feedback mechanisms that accommodate both

XSL•FO
RenderX

patient needs and provider oversight requirements in the design of the 3D ARS.

Usability and User Experience Considerations for 3D ARS for Older Adults

Beyond feedback mechanisms, participants emphasized the importance of system usability and ease of interaction when engaging with AR-based rehabilitation technologies. In particular, features such as voice activation and the ability to pause and resume exercises were identified as important for supporting interaction with the 3D ARS. Significant differences between older adults and service providers also emerged for these usability-related features, suggesting that flexibility in how users interact with and control the system may be an important consideration in the design of home-based rehabilitation technologies. Usability is a critical determinant of engagement with digital health technologies, particularly among older adults [47]. Technologies that are difficult to navigate can create confusion and frustration, which may reduce sustained engagement and limit the effectiveness of digital rehabilitation interventions [48,49]. Designing AR-based systems that prioritize intuitive interaction and flexible system control may therefore support greater engagement and usability in home-based postoperative rehabilitation.

Privacy-Preserving Motion Tracking and Data Sharing Considerations in AR-Based Rehabilitation

In addition to usability considerations, participants and system designers must also consider privacy and data management issues associated with camera-based rehabilitation technologies. We propose the use of artificial intelligence–based pose estimation as a promising approach for balancing the need for meaningful movement analysis with concerns related to privacy and data management in home-based rehabilitation. By converting video input into a simplified 3D skeletal representation of the body, the system will capture key movement information while removing identifiable visual features such as facial characteristics, clothing, and background details. This approach may help address privacy concerns that often accompany camera-based monitoring technologies, which can be a barrier to adoption in home environments. In addition, the system focuses on the individual closest to the camera, thereby minimizing the unintended capture of other individuals in the home.

Beyond privacy considerations, the skeletal representation substantially reduces the amount of data generated during exercise sessions compared with full video streams. This reduction in data volume facilitates efficient storage and transmission of exercise information and supports the feasibility of local data storage directly on the console. Such efficiency may be particularly important for in-home rehabilitation contexts where internet connectivity or bandwidth may be limited.

Importantly, this approach also enables flexible models of information sharing with health care providers. At the most basic level, individuals can retain full control over what information is shared by verbally communicating their progress or challenges during follow-up consultations. Alternatively, the system could generate automated summaries of exercise performance, including indicators such as repetitions completed, trends in performance, or potential anomalies. These summaries could be shared manually or electronically through secure communication channels. When more detailed monitoring is required, anonymized skeletal data could also be transmitted to clinicians, enabling more precise review of exercise performance while maintaining a high level of privacy protection.

Taken together, these features suggest that artificial intelligence–based pose estimation may offer a viable pathway for integrating motion tracking into AR-based home exercise systems in a manner that supports both patient privacy and clinical oversight [50]. Such approaches may help address key implementation challenges associated with remote rehabilitation technologies and support more scalable models of home-based care [51,52].

Clinical Integration and Access to AR-Based Rehabilitation

Our findings raise important considerations regarding health equity in the implementation of technology-based rehabilitation. Physiotherapy clinics may vary in their capacity to integrate and support technology-enabled interventions over extended periods, and not all patients may have equal access to such resources due to geographic, financial, or systemic barriers [53]. Addressing these challenges during system development and implementation will be critical to ensuring that the benefits of the 3D ARS are scalable and equitably distributed.

Within this context, participants recommended that access to the 3D ARS be facilitated through physiotherapy clinics, initiated early in the postoperative period, and maintained for at least 6 months. This finding aligns with previous work highlighting physiotherapists' central role and expertise in exercise prescription for older adults with TJR [54]. Situating access within clinical settings may also ensure that the use of the 3D ARS is guided by professional oversight, reducing the risk of misuse while positioning the system as a complement to conventional rehabilitation care.

Cost, Digital Equity, and Access to Rehabilitation Technologies

Other issues identified include the potential cost of the 3D ARS and a lack of access to suitable exercise equipment to complete the recommended exercises at home. Overall, participants' perspectives on costs highlight issues of digital equity and the importance of efforts to address the existing divide in access to digital infrastructure, which gives some individuals advantages over others [55]. To address these concerns, the proposed 3D ARS will leverage a relatively simple hardware configuration similar to existing motion-based gaming consoles, in which a camera-based console connects directly to a television or monitor. Such an approach could facilitate easy integration into home environments while minimizing installation complexity. By using commonly available household electronics, such as a TV or monitor, this configuration may also help reduce system costs and improve the feasibility of implementing AR-based rehabilitation technologies in the home.

XSL•FO
RenderX

Supporting Independent Use of the 3D ARS Through Accessible System Design

Finally, the lack of confidence in the 3D ARS setup identified by older adults highlights the importance of incorporating robust training supports and designing intuitive, user-friendly setup procedures [56]. Embedding step-by-step guidance, interactive tutorials, and a clear user interface design within the system itself could increase user confidence while reducing cognitive load and reliance on external assistance. Such design choices not only empower users to engage more independently but may also help minimize system development and implementation costs by reducing the need for dedicated technical support staff to resolve setup issues.

Overall, these findings highlight several key considerations for the development of AR-based rehabilitation technologies for older adults following TJR. Participants emphasized the importance of systems that combine individualized exercise programming, accessible and intuitive user interfaces, and timely feedback mechanisms that support motivation and adherence. At the same time, our results underscore the need to balance technological capabilities with practical implementation considerations, including privacy protection, clinical oversight, and equitable access to digital rehabilitation resources. By incorporating these user-informed priorities into the design of the 3D ARS, future systems may better align with the needs of both patients and rehabilitation professionals, supporting scalable models of home-based rehabilitation that complement conventional care.

Limitations

Several limitations should be considered when interpreting the findings of this study. First, participants were asked to evaluate proposed features of a 3D ARS rather than interacting with a fully functional system. As a result, the preferences expressed may not fully reflect experiences with actual system use during postoperative TJR rehabilitation. Future studies should examine user experiences with prototype systems to better understand usability, engagement, and clinical effectiveness in real-world contexts.

Second, the sample included a relatively highly educated group of older adults, which may limit the generalizability of findings to individuals with lower levels of education or digital literacy. Because comfort with technology can influence perceptions of digital health tools, the perspectives captured in this study may not fully represent the broader population of older adults undergoing TJR.

Third, the cross-sectional design captures participant perspectives at a single point in time and does not account for how preferences may evolve during different stages of postoperative recovery or with increased familiarity with digital rehabilitation technologies. Longitudinal research may provide additional insight into how user needs and expectations change throughout the rehabilitation process.

Finally, although participants were recruited from multiple regions, a substantial proportion of the sample was located in Ontario. Health system structures, access to rehabilitation services, and availability of digital infrastructure may vary across regions, which could influence the transferability of these findings to other settings.

Conclusions

This study identified key design priorities for a 3D ARS to support home-based physical rehabilitation for older adults recovering from TJR. These findings provide an important foundation for the development of AR-based rehabilitation technologies that respond to the needs of end users and rehabilitation professionals. Future work will focus on user-centered system development, prototype testing, and usability evaluation to support the implementation of a practical and scalable AR-based rehabilitation solution.

Acknowledgments

The authors would like to thank Poornima Kamath and Helen Rosseau for their contributions to the survey design.

Funding

This research was supported by the National Research Council Canada’s Aging in Place Program.

Data Availability

The data generated and analyzed during this study to support the findings are included in this published article and its supplementary files.

Abstract

Background: Digital technology is increasingly being used to deliver interventions and initiatives to support the well-being of older adults. However, few studies have conducted needs assessments to identify the future well-being service requirements of an older adult population and their preferred modes of delivery, whether via digital technology or, in- person, or a combination of both (ie, a hybrid model).

Objective: This study aims to investigate the requirements of a rural region in New Zealand to inform planning to meet the future well-being needs of its older adult population over the next 30 years.

Methods: In total, 2 focus group discussions and 13 interviews were held with participants using a combination of phone and video calls. A total of 31 adults aged 61 years or older participated. The participants were asked how they saw the future well-being needs of the older adult population evolving, the role of digital technology and/or in-person interactions in delivering well-being services, and perceived barriers to, and enablers of, digital technology for providing services. Focus group and interview transcripts were thematically analyzed.

Results: A total of 4 key well-being themes were identified across both focus group discussions and interviews with participants: —"services," "support," "spaces," and "social connection," —with an overarching finding that future age-friendly planning must prioritize social and community well-being outcomes, ensuring that investments in services, digital inclusion, and public spaces strengthen older adults' ability to connect with others and participate fully in community life.

Conclusions: Digital technology is developing at a rapid pace, and as a result, we need to consider how to plan for the transition and bridge the gap identified between the current use of digital technology and its potential future use if technology is to support the older adults of the future. The findings indicate that older adults prefer to engage in- person, while trust is a barrier to digital technology use for some participants. The future offers many opportunities to support the well-being of older adults and communities through the application of the proposed 4 Ss Framework.

KEYWORDS

older adults; digital literacy; digital health; social connection; social isolation; well-being; trust; technology adoption; rural health services; health equity

Introduction

Background

The World Health Organization (WHO) frames health as a dynamic resource that enables people to meet their needs and aspirations [1]. This broad understanding recognizes that health and well-being are shaped by the wider environment in which people live, and many determinants of health exist outside of the traditional scope of the health sector [2]. The WHO applied these determinants to the health and well-being of older adults to promote the concept of "active aging" through its Active Aging Framework [3]. The Healthy Ageing Strategy in New Zealand [4] considers that older people should live well and age well in "age-friendly" communities, thus linking active aging with Age-Friendly Cities and Communities (AFCC).

Van Hoof et al [5] developed their model of the age-friendly city with 8 domains that align with the WHO dimensions of active aging: outdoor spaces and buildings;, transportation;, housing;, civic participation and employment;, respect and social inclusion;, social participation;, communication and information;, and community support and health services. This is very similar to the 5 key areas identified by the Office of the Seniors "Better Later Life–He Oranga Kaumātua 2019 to 2034" [6].

XSL•FO
RenderX

Much of the research around AFCC is at a conceptual or pilot stage and focuses on only specific components for AFCC, and the metrics used to assess AFCC interventions are limited [7,8]. Interventions vary and may include the improvement ofin health risk factors for health, positive behavioral lifestyle changes, changes in organizations, and changes in the domains of AFCC, with the majority having a combination of environmental and psychosocial interventions [7]. Examples include safe and friendly housing, transportation, social inclusion and participation, outdoor spaces and buildings, communication, and information [7].

Smart Cities and Communities, AFCC, and Active Aging

The WHO emphasizes promoting healthy aging in a digital world [9] and identifies loneliness and isolation as critical public health issues requiring urgent intervention [10,11]. The WHO's extension of the Global Digital Health Strategy to 2027 further underscores the relevance of integrating digital solutions for aging populations worldwide [12].

At its most basic, "smart cities and communities" are cities and communities that are interconnected by digital technology and are data-driven, using AI, to achieve better lives (well-being) for all residents. However, they are not without their own problems [13,14], as the predominant technologies used are the Internet of Things (sensors) and AI [15,16], each of which comes with design, implementation, and sustainability issues. Pedell and Borda [17] combined smart cities, AFCC, and active aging, with 3 of the WHO domains to bring in the digital aspect (Smart) in their conceptual model: a simplified version of the AFCC model by Van Hoof et al [5]. When tested, similar to the authors' previous research [13,14], they found that digital technology can reduce social isolation, increase social participation, and increase independence. Pedell and Borda [17] suggest that digital technologies may have a wider role to play in AFCC.

New Zealand Context

Against this international backdrop, this study explores how one New Zealand community is preparing to meet the future well-being needs of its older population. In New Zealand, it is critical that health and well-being are considered under the obligations of Te Tiriti o Waitangi [18] and through a bicultural lens, reflecting Ma¯ori perspectives of health. This approach is embodied in the Te Whare Tapa Wha¯ model [19]. Te Whare Tapa Wha¯ defines well-being across 4 interconnected dimensions: physical health (taha tinana), spiritual health (taha wairua), mental/emotional health (taha hinengaro), and family/social health (taha whānau) [19]. These perspectives extend the concept of well-being beyond individual health to include social and community well-being, which are fundamental to Ma¯ori, who operate within a collective-based society [20]. This study applies a holistic interpretation of well-being that is consistent with Te Whare Tapa Wha¯ and New Zealand's bicultural health context.

Methods

Study Design

This qualitative exploratory study sought to examine the future well-being needs of older adults residing in a small town and its surrounding rural community, with the aim of informing planning for future service delivery.

Setting and Context

This study was conducted in a developing rural area in New Zealand's North Island, historically settled by retired farmers, and characterized by dispersed settlements, limited transport options, and variable internet connectivity. As of 2024, the region had a population of 33,700 people of whom 19.6% were aged ≥65 years [21]. Travel across the region can take approximately 90 minutes. These contextual features create both challenges and opportunities to inform future planning for well-being-related services for an aging population, making older adults a central consideration for this study during the design and analysis stages.

Participants and Eligibility

The eligibility criteria were community-dwelling older adults born between 1940 and 1960 and residing in the region at the time of data collection. This cohort requirement was set by the project funder.

Recruitment

Participants were recruited through purposive sampling [22] to ensure diverse perspectives by gender and ethnicity including: male and female participants, Māori, and other non—New Zealand European participants. Recruitment strategies included posters placed in community venues, notices disseminated via local organizations, posts on community Facebook pages, and the researchers' existing contact networks. These traditional methods of in-person recruiting and using paper-based marketing material were adapted during the recruitment process because the national COVID-19 pandemic lockdown settings prevented in-person contact at the time of data collection. Participation was voluntary. Participants could bring a support person, decline to answer questions, withdraw, and access translation services if required. All participants provided either written or verbal informed consent prior to participation. Verbal consent was an added option for participants due to the restrictions imposed by COVID lockdowns, and returning a scanned informed consent sheet was difficult for some. These recruitment strategies were designed to capture a diverse range of perspectives and ensure cultural inclusivity.

Data Collection

Data collection occurred between April 5 and May 11, 2022. The project was originally designed to include up to 6 in-person focus groups (a maximum of 40 participants) with older adults born between 1940 and 1960. National COVID-19 pandemic lockdown settings prevented in-person focus groups and necessitated a mixed approach, combining 2 semistructured online focus groups (n=18), three online interviews (n=3), and telephone interviews (n=13). This adaptation of the study's design also addressed some of the challenges experienced by

XSL•FO
RenderX

participants when using digital platforms (such as videoconferencing via Zoom), technical difficulties such as inexperience in using these digital platforms, rural internet connectivity challenges, and preferences for individual interviews. Scanning consent forms was a particular challenge and was addressed using recorded verbal consent.

The adaptive approach taken regarding the initial methodology is consistent with previous rural telehealth research, which shows that flexibility is often required when engaging older populations in digitally constrained contexts [23].

Participants self-rated their confidence in using digital technologies and provided demographic details on age, ethnicity, and gender. Semistructured questions [24] were provided in advance to encourage reflection, a strategy that has proven effective in earlier research [23]. The same questions were used across phone interviews and focus groups for standardization. Four questions, with prompts, structured the sessions (Table 1).

Table . Questions for focus groups and phone interviews.

Question number	Summary of questions covered
1	How do you see the well-being needs of your community evolving over the next 30 years? What types of community services will be required?
2	Should these services be delivered in- person, digitally, or in a hybrid form?
3	What concerns or barriers might you have in using digital technology to meet the community's well-being needs? What mitigating factors are required to address these?
4	What benefits could digital technology offer (eg, savings on time, travel, or costs)?

Data Analysis

An inductive thematic analysis was undertaken [25,26]. All focus groups and phone interviews were audio-recorded, transcribed verbatim, and anonymized, and the data were managed in NVivo (Release 1.6.1; Lumivero). Initial codes were generated, grouped into categories, and refined into overarching themes. Coding decisions and analytic notes were documented to ensure transparency, and themes were reviewed against the full dataset for accuracy. Two researchers coded the data independently and resolved any differences through discussion. The final analysis identified 4 key themes, summarized as the "4 Ss Framework": services, support, spaces, and social Connection.

Ethical Considerations

The project followed the Massey University Code of Ethical Conduct for Research, Teaching and Evaluations Involving Human Participants [27] and was judged by peer review as low risk, including suitability from a Māori research perspective. A low-risk notification was recorded with Massey University's Human Ethics Committee [28]. Māori research ethics considerations were reviewed to ensure cultural appropriateness and responsiveness to Te Tiriti o Waitangi, and the findings were reviewed from a Māori perspective to ensure appropriate interpretation. All participants gave informed consent, and participant involvement was entirely voluntary; privacy was preserved by anonymizing the data, and data were kept secure and confidential as per the university data management guidelines. Participants did not receive financial compensation.

Results

Participant Characteristics

A total of 31 older adults aged 61 to 82 years participated, and 45% (n=14) identified as male and 54% (n=17) as female. To allow for birthdays later in the year, the eligibility criteria allowed for 61-year-old participants on the date of data collection.

The majority identified as New Zealand European (n=26, 86%), Māori (n=4, 13%), and "Other" (n=1, 3%), based on the Statistics New Zealand ethnicity classification system [29]. Māori participants were slightly underrepresented when compared to local population data for both the region (18%) and the national population (17%) [30,31]. Findings indicated that 18 (58% (n=18) of participants reported that they were somewhat, or very confident using technology (Figure 1), including the oldest participants, and 63% (n=19) of Manawatū resident participants self-reported as very/ confident or somewhat confident using technology. Table 2 shows the demographic characteristics.

In the findings section, where a participant could be identified with a participant ID, this has been provided. Some quotes are from focus group participants, in which case the relevant focus group participant IDs are provided.

P31	Phone interview	Māori	Female	65	Somewhat confident

Thematic Findings: The 4 Ss Framework

Thematic analysis identified 4 interrelated domains of well-being—services, support, spaces, and social connection—which together form the 4 Ss Framework. Table 3 presents these overarching themes and their associated subthemes. These themes reflect priorities identified by participants when considering what older adults will need to age well over the next 30 years, as required by the project funder.

XSL•FO
RenderX

Table . Themes and subthemes (4 Ss Framework) identified by participants.

Theme	Subtheme
Services	Transport, housing, health care, and communication
Support	Digital technology, connectivity, safety and security, information
Spaces	Existing facilities, purpose-built social spaces, technology hubs, and hybrid (digital and physical spaces)
Social connection	In-person interactions and socializing, loneliness and isolation, feeling part of the community, Te Ao Māori, and connection

Theme 1: Services

Participants consistently emphasized the importance of services that sustain independence and well-being, particularly transport, health care, housing, and communication.

Transport

Transport emerged as the most pressing concern. Rural participants described high fuel costs, limited public transport, and mobility barriers to reaching bus stops. Some worried about dependence on family: "I can get lifts, but I don't want to be dependent on others" (P1). Alternatives suggested included subsidized taxis, shuttles, and mobility scooters. Participants considered autonomous (self-driving) cars as viable future transport options, where one said, "I'm looking forward to autonomous cars when I stop driving" (P6). Taxi services were considered better for social interaction and more personal than taking the bus.

The prospect of losing a driver's license generated considerable anxiety: "I am dreading what happens if I can't drive" (P2). Participants linked this to reduced social interaction and an increased risk of isolation and loneliness: "I hate the idea that we can't go out at night" (P3).

Housing

Housing affordability and limited options constrained the ability to relocate closer to services or family,: "Housing developments are currently targeted to those who are well off financially" (P21). Mixed developments that combine public, private, intergenerational, and sheltered housing were widely supported. "The actual village has young people and children and families and workers and retirees and unemployed, that is the sort of caring community I would like to see for the ageing population" (P3).

Smart home technology in housing was generally regarded positively. Different levels of familiarity with smart home technology were recognized by participants,; "some people in NZ already have semi-intelligent houses, already know how to use Alexa and technological gadgets" (P5), while another acknowledged that "people that haven't grown up with [it] are going to need the reassurance that they can use these things in the next 30 years" (P6).

Health Care

Health care was another key issue. Concerns were raised about limited local providers, long wait times, and travel distances for rural residents. These concerns ran the full gamut of health care, including emergency care, acute care, long-term care, disability support, including support for low vision and deaf communities, mobility, and dementia care. Changes discussed included walk-in clinics, different opening times, and reduced waiting times, with one participant likening the current health service to "a very slow train crash" (P3). Some participants recollected the district nurses' home visits and expressed concern about their decline. Cost was raised as a general issue, ("Living off the pension now is prohibitive, power, phone, insurance, …." ([P27]) and specifically around private health insurance ("By the time you need your health insurance, you can't afford it, it is too expensive" ([P3]).

Telehealth (Tthe interpretation of Telehealth applied here is "the use of digital technology to deliver health care when participants are separated by distance and/or time." [32]) was valued because it gives "the ability for medical practitioners to see into your life where you are more relaxed" (P7). However, downsides raised about telehealth included: confidence, digital skills, and access to technology or connectivity. Participants expressed a clear preference to have the option of in-person consultations and acknowledged that telehealth could not replace all aspects of health care. "You can see a dead cow out there on a drone, or a cow lying down, you don't know what's wrong with it until you go up and see it" (P30).

Delivery of medications by drone (P9, and P24) was of particular interest to rural participants because accessing the local pharmacist required lengthy road trips. Unlike other rural areas, where the local rural bus can deliver medications (and shopping), many rural residents in the study area have no option but to drive to the local pharmacy in town.

One participant with low vision commented: "For our mental health, one of the main things is we need someone who we can connect with, who understands us as an individual, and we feel is on our side, that we can say, 'this is what I am doing, how do I go about it'" (P29). Health and loneliness can be intertwined, and for example, "Isolated people feel pain more than those socially connected" (P3).

Communication Gaps

Communication gaps were seen as a significant issue, especially as both rural and urban populations increase,: "the bigger the place gets, the worse the communication gets" (P5). Many participants lacked timely information about services, events, or smaller community groups, constraining their ability to access services, which would improve their social connection. This was exacerbated for people who were isolated, new to the community, or did not have English as their first language. While community groups exist, "there is no overarching

XSL•FO
RenderX

facilitation of these groups spreading the word" (P7), illustrating the opportunity for community navigators to share information to improve social connection.

Digital tools provided opportunities to communicate, but barriers such as cost, skills, and access excluded some older adults: "A large proportion of the population can't communicate using tech, or don't want to" (P2), and one participant commented that "There was an online survey for the rural bus service, I got it when it was sent out, but couldn't save it on the computer–not like pinning it on the fridge with a magnet" (P1). On the other hand, digital technology assisted with communication,: "Technology allows people to be in contact with friends who live far away" and "translation devices help people connect despite the language barrier" (P22).

Theme 2: Support

Discussions about support centered on the importance of digital literacy, reliable connectivity, support for safety both online and personal safety, and the developing skills around information management.

Digital Technology

Participants recognized the increasing integration of technology in daily life (including as a tool for sharing information) and acknowledged its advantages, including online banking, virtual travel, and telehealth. However, participants also voiced strong concerns about being excluded due to limited access, affordability, or digital literacy, noting that "as time goes on people will have to accept technology" (P11-P20). The rapid rate at which digital technology is changing was considered a barrier,*:* "This is why some people give up, and then they become isolated" (P5).

Some participants reported using devices to connect with family overseas or for entertainment. Barriers to the uptake of digital technology by older adults included low confidence and digital skills,: "Older people are feeling cut out because they aren't technologically literate" (P11-P20), fear of scams, and associated costs with "trust is a huge barrier to people using technology" (P21).

Support groups are one way of addressing low confidence and digital skills: "with the Blind Low Vision [support group], we have been learning how to use Alexa and Siri, but once you get to people age 65 - 70, anything digital is hard work if you don't understand the workings" (P28) and "I also have hearing problems, which a lot of people probably have both problems with vision and deafness" (P29). P29 added that, "the Blind Low Vision person came over and showed me how to use Siri on my phone, I now ask the phone for location directions."

Connectivity bBarriers

Connectivity barriers included unreliable rural internet and phone coverage, unclear pricing, and restrictive data caps, which exacerbated digital exclusion for older adults. Several participants stressed that knowing about and using relevant apps was as important as the infrastructure itself,: "the online communication will only work if people know about the apps, have the apps, can use these and have access to the technology" (P9). Unreliable coverage was perceived as a barrier to engagement: "You can't give your mobile number out, because no one can contact you when you get home" (P8) (due to variable coverage).

Safety and Security Concern

Safety and security concerns were a broad topic, including housing security, especially when living alone, feeling safe when out and about or at home (not just from physical attacks but from falling or injuring themselves), trusting people who came to the house such as trades people, and so on. Participants suggested that pedestrian crossings require level access and "Cross Now" audio signals that are loud enough for people who are deaf or have hearing loss to improve their safety.

Some participants did not know how to improve their internet connectivity and often worried about whether they had completed their online banking or email transactions successfully. This led to frustration and an increased fear around using the internet for certain activities. Concerns heightened when phishing was discussed, because participants worried about online fraud and their ability to recognize it,: "I cancelled my card and started from scratch again, my children helped me with that. What was scary was that the person on the phone [from the bank] said, 'you would be surprised how often that happens.' I don't know what we can do about tightening up security on devices" (P23). In addition, there can be a level of discomfort seeking help with sensitive digital tasks such as banking,: "Older people may not want strangers to help with certain aspects of technology" (P22).

Information

Information, and in particular, digital literacy, emerged as a recurring theme. As more services move online, participants are concerned about their ability to search, verify, and store information effectively,: "if older adults are active in the community, they will get information but if [they are] at home they will be isolated and not get the information" (P27). Concern about managing the "social media afterlife" (P5) following death highlighted the need for better guidance. Practical, community-based training to improve digital skills was strongly supported.

Theme 3: Spaces

Spaces for social connection and well-being were considered essential, with a preference for adapting existing facilities over constructing new ones to enable in-person interactions.

Existing Facilities

Community venues, such as halls, cafés, and churches, were described as underused yet valuable resources: "We don't need new buildings, but we should utilisze what we have" (P10, P27).

Purpose-Built Social Spaces

On the other hand, building new social spaces designed to accommodate the needs of the community by being age-friendly and accessible was considered necessary–"We need more community buildings in place" (P4, P27). Barriers identified included cost, compliance requirements, and physical accessibility challenges. Participants expressed a preference for

XSL•FO
RenderX

casual, spontaneous use of spaces, particularly cafés as community hubs.

Technology hHubs

Technology hubs co-located in libraries or health care centers were recognized as preferred spaces for supporting informal learning and scheduled training. One participant identified that "The library could encourage people to come together–they tend to do this with other groups, but not necessarily older people" (P4). These shared spaces could also support tasks such as logging into patient portals by providing technological support.

Hybrid Spaces

Hybrid spaces that allow both in-person and online participation were considered particularly valuable for individuals with low vision, mobility, or transport challenges. It was proposed that delivering introductory in-person training (eg, teaching videoconferencing skills) would increase older adults' confidence and willingness to engage online. As one participant said, "We could have an in-person session initially to show us all how to use Zoom, so we would feel more comfortable" (P2).

Theme 4: Social Connection

Social connection (also known as social connectedness) was consistently identified as a cornerstone of well-being.

In-Person Interactions and Socializing

In-person interactions and socializing had the most impact on well-being in all the focus groups and interviews. Most conversations concluded with a discussion highlighting the importance of socializing in person. In-person connection was perceived as irreplaceable, with digital tools valued only as supplementary supports. As one participant explained, "We are lucky in that we all belong to each other, we are whakapapa, and we can talk to each other, but in other communities that is not the case where they are diverse" (P24).

Everyday connections through clubs, volunteering, and informal gatherings provided purpose and belonging, with some attending clubs "for the interaction" (P10) rather than for the activity itself. Intergenerational contact, whether with family or through community programs, was described as enriching and valuable for participants,: "Mixing with the local youth is a win" (P10).

While digital platforms supported social ties during the COVID-19 lockdowns, participants agreed that physical spaces and in-person connections were essential to their well-being. Participants were clear that virtual options should complement, not replace, in-person contact.

Loneliness and iIsolation

Loneliness and isolation were attributed to a lack of social connection in the community, limited inclusive spaces, or inadequate access to digital technology, and were further linked to limited mobility or a recent relocation to the region.

As one participant stated, "without a Tablet or Smart phone, older adults miss out on the connection, and struggle to get information" (P27). New residents, in particular, described difficulties integrating and, at times, feeling unwelcome in established communities. Participants were very keen to explore social prescribing and community well-being navigators, both strategies deployed in New Zealand and overseas to increase social contact and connection, "if there was a connector that would help" (P7).

Another participant commented, "For a lot of us, it is family, I have quite a few friends who are on their own, and it is hard. I see that digital can help, but there is nothing like a person who doesn't look like they are in a hurry to get to the next job – they have time" (P29).

Not Part of a Community

Participants were concerned that newcomers from urban areas often preferred to keep to themselves and often worked from home or commuted to larger urban centers, coming home to relax. They felt that these new residents did not always recognize the importance of social and community connection and were therefore less likely to engage in community activities.

Even existing residents can feel disconnected from the wider community, with their only contact being through social services: "I deliver meals on wheels, and it's obvious that a lot of people have no contact other than the person bringing their meal" (P23).

Te Ao Māori and Connection

Māori participants emphasized the value of cultural connection—"I would be more comfortable talking to you face to face, as opposed to this (Zoom)" (P30)—including the central role of marae (Māori meeting places), which operates as multifunctional hubs that provide cultural, social, and increasingly digital engagement. A number of marae now offer fast internet, enabling them to serve as hybrid spaces, as one participant noted: "*Y*es, there is Wi-Fi on the marae…but not in our houses" (P24). This can also provide support in using technology, with one participant observing, "Technology for our community, we have old people out here (The Valley), they don't even know how to operate a mobile phone" (P31).

Discussion

Principal Findings

The 4 Ss Framework (Table 3) provides a practical lens for understanding future well-being priorities in a regional older adult population by highlighting 4 priority areas for future planning for age-friendly, inclusive communities: services, support, spaces, and social connection. Notably, participants described well-being as relational and community-based, reflecting Māori perspectives that emphasize collective rather than solely individual determinants of health. Social and community well-being emerged not only as one of the 4 Ss but also as a determinant that influences access to services, digital engagement, and the use of physical spaces.

The approach proposed aligns with internationally recognized social determinants of health and well-being [2] and the WHO dimensions of active aging [3]. The thematic findings presented here also reflect the models of Van Hoof et al [5] and Pedell and Borda [17], which emphasize the interplay between environments (spaces), service access, and social participation

XSL•FO
RenderX

in shaping aging experiences. Despite reporting confidence with using digital technologies, participants' difficulties in participating online reflected limited skills and low trust in digital systems, illustrating a gap between perceived and actual digital literacy.

These findings confirm and extend prior research demonstrating links between social isolation and poorer health outcomes [33] that telehealth faces persistent equity barriers [34] and the need to co-design housing and transport to support aging in place [13]. Alignment with global and national policies on active and healthy aging, the WHO's Global Network for AFCC [35] and New Zealand's Healthy Aging Strategy [36], is also evident due to their emphasis on transport, housing, communication, and participation as the foundation of age-friendly environments. Similarly, New Zealand's Better Later Life–He Oranga Kaumātua 2019 to 2034 strategy [6] sets a vision to enable participation and value contributions as people age. The alignment of this study's findings within a wider policy context highlights their relevance for future planning.

Most participants commented that younger generations are more digitally literate than older generations, suggesting that communities are experiencing a transition phase, with any perceived lack of digital skills primarily affecting today's older adults and possibly the subsequent generation.

Services

Participants highlighted concerns related to financial insecurity, isolation and loneliness, safety and security, stress and anxiety, and limited access to social services. Challenges in accessing social services can disproportionately affect people who are deaf or have hearing loss, as well as those with low vision, especially those without standard forms of identification, such as a driving license. Looking to the future, essential foundations for aging well in place included the importance of reliable access to health care, housing, transport, and information.

Enabling access to reliable and safe transport supports social participation and inclusion because the older adults' ability to engage in- person is contingent on accessible mobility options, an essential principle in universal design and age-friendly environments [37,38]. Autonomous (self-driving) cars were considered viable and realistic future options, either as owner-user or taxi-based models, and the deployment of these technologies is already emerging internationally [39-41]. Shu and Woo [42] anticipate that autonomous mobility may help reduce older adults' social and geographic isolation by overcoming transportation barriers. These access challenges ultimately constrained opportunities for social participation and inclusion, demonstrating the importance of treating social well-being as a core service outcome.

Health care concerns focused on access, long waits, and rural service gaps. Participants viewed telehealth and wearable technologies as useful in supporting in-person care within a hybrid delivery model. However, they emphasized that telehealth could not replace all aspects of health care and that retaining the option for face-to-face consultations remains essential for many older adults [23]. This finding reflects global evidence that the effectiveness of telehealth depends on confidence, digital skills, technology availability, and reliable connectivity [34,43-45]. Social isolation, and its impact on health, emerged as a key concern for participants, reinforcing international findings that social isolation can exacerbate pain and reduce participation in daily activities [33].

While participants in this study did not raise cost as a specific barrier to health care, this may be due to the population sampled, as several reported holding private health insurance, although many found it too costly to maintain. Despite universal health coverage being the predominant funding model in New Zealand, around 33% of the population buy additional private health insurance at some point [46]. However, in New Zealand's *Better Later Life–He Oranga Kaumātua 2019 to 2034* strategy, cost was clearly identified by older adults as a barrier to health care and well-being, for example, in relation to visiting the doctor and dentist [6].

Housing affordability and diversity of types of housing were equally pressing needs, with participants supporting smart home technologies and universal design features to enable aging in place. Smart home sensors can support safety and daily activities, enabling more older adults to age in place, which is associated with better health outcomes than relocating to assisted living [13,14]. International evidence identifies that early integration of universal design reduces costs and supports disability-inclusive housing [13,14]. Jacques [47] has argued that any new house has a 60% probability of accommodating someone with a disability during the lifespan of that house. Transport and housing are interlinked, with the location and design of new developments requiring integration with accessible public and active transport options to avoid environments that limit older adults' mobility, social participation, and inclusion and thereby creatinge islands of isolation [48].

The transition from print to digital was seen as a significant communication challenge that risks excluding those lacking digital access or skills, thus increasing social isolation [49]. This reflects broader international concerns that digital transitions can exacerbate inequalities in information access, leading to digital exclusion for some communities [50,51]. Seifert et al [52] found that older adults often feel excluded when essential communication moves online without alternative nondigital alternatives. Vaca-Benavides et al [53] also caution that digital transitions in health and social care services can exclude older adults who struggle with digital confidence, access, connectivity, or support.

Support

Trust in digital technology, in the systems that support it, and in participants' own ability to use it emerged as a significant concern and presented issues with information access. Barriers identified included cost, the rapid pace of technological change, and limited training opportunities. One option to address this is to provide community well-being navigators (through local libraries) to support older adults with digital literacy and increase their confidence in the use of digital technologies [54]. Vercruyssen et al [55] observed that for older adults with minimal or no prior experience with digital technology,

XSL•FO
RenderX

acquiring even the most basic or entry-level digital literacy skills is difficult.

Internet and phone connectivity issues, experienced particularly by participants living in rural areas, compounded these barriers to equitable digital access. Even in areas with theoretical internet coverage, participants experienced unreliable connections, consistent with national and global studies highlighting the last mile of the digital divide [23,56].

The participants also raised safety and security concerns about the use of digital technologies, including online risks (eg, fraud and identity theft) and physical vulnerabilities. Technologies such as alarms and GPS trackers were predominantly welcomed, especially for dementia care; however, participants' low levels of trust presented barriers to digital engagement. Kebede et al [57] reported that safety and digital confidence issues represent key barriers to digital engagement, particularly in relation to web-based digital technologies. The ability to access digital information and community services was considered essential to well-being [43], because unreliable access increased the risk of social isolation.

Digital literacy is essential for civic participation and safety. Older adults are at risk of digital exclusion without targeted support [55]. Digital skills therefore support more than information access; they enable older adults' civic participation and social connection, which is critical to community well-being. Seifert et al [52] described a "double burden of exclusion" affecting older adults who face both digital and social exclusion. Other research illustrates that affordability, trust, and skills gaps continue to drive digital exclusion among older adults [58,59], mirroring the findings of this study.

Spaces

Accessible, inclusive, and multifunctional community spaces that support social and recreational activities were considered essential for well-being. One key finding was participants' clear preference for reusing existing facilities as social spaces, such as community halls, cafés, and churches, rather than building new ones, which is consistent with international research. Liddle et al [60] recognized the importance of making better use of existing spaces to improve social connections and considered how to repurpose them. Barriers identified to repurposing shared spaces included cost, compliance requirements, and accessibility challenges. Integrating age-friendly universal design into both housing and public infrastructure could reduce these barriers and promote independence, because urban design influences opportunities for social engagement and inclusion [61]. Physical places that enable social connection were regarded as essential infrastructure for community well-being, not merely a venue for activities. With older adults' strong preference for in-person interaction, it is essential that we retain and repurpose existing spaces to support their well-being. While digital technology can complement these physical spaces, it cannot substitute for them, particularly for those at risk of digital exclusion.

Social Connection

Social and community well-being emerged as a key determinant of healthy aging, influencing participation, belonging, and independence across all aspects of daily life. Social interaction, particularly in-person connection, was consistently described as essential to well-being, especially for those with low vision and hearing loss. A lack of social connection was perceived to contribute to loneliness and isolation, negatively impacting mental health. International research has similarly identified that increasing opportunities for in-person social contact can reduce loneliness and improve well-being in older adults, consistent with the findings of this study [61].

Participants emphasized the value of social prescribing [62] and community well-being navigators [54], both of which are emerging as strategies in New Zealand and internationally to increase social contact and reduce isolation. Māori participants emphasized the importance of marae as multifunctional hubs, reinforcing indigenous models of well-being where holistic dimensions are interconnected. The exploration of marae-based approaches, and similar collective spaces, is recommended to strengthen belonging and intergenerational ties to support social connection. Participants expressed a clear preference for approaches that combine digital access with ongoing in-person contact, such as hybrid models, reflecting findings internationally that found face-to-face interaction crucial for older adults' well-being [63-65].

In summary, these findings suggest that future age-friendly planning must prioritize social and community well-being outcomes, ensuring that investments in services, digital inclusion, and public spaces strengthen older adults' ability to connect with others and participate fully in community life.

Recommendations

The 4 Ss Framework is proposed as a planning framework for future age-friendly, inclusive communities: services, support, spaces, and social connection. It can be used to assess current opportunities, identify gaps in existing opportunities, and thus inform future planning. Using the framework, the authors propose a set of actionable recommendations to guide planning for age-friendly regional communities over the next 30 years. Table 4 summarizes these recommendations, offering actionable guidance for service providers, policymakers, and community organizations. This is also an example of how a community could use the framework for its future age-friendly planning.

These recommendations, drawing on the 4 Ss Framework, are designed to inform future planning for age-friendly regional communities over the next 30 years, as well as corresponding policy and practice implications. The findings highlight the importance of hybrid service models, digital inclusion, universal design, and social connection and emphasize the importance of embedding aging perspectives in policy and planning. Finally, most participants commented that younger generations are more digitally literate than they are, suggesting that communities are experiencing a transition phase , with any perceived lack of digital skills primarily affecting today's older adults, and possibly, the subsequent generation.

The future offers many opportunities for supporting the well-being of individuals and communities, and the findings of this project are supported by existing models of wellness. Using the models and strategies in the literature, highlighted by this thematic analysis and the Te Whare Tapa Whā model, it is

XSL•FO
RenderX

possible to create a matrix to direct planning and evaluation of interventions and initiatives to improve wellness in age-friendly communities that meet Te Tiriti o Waitangi obligations and align with New Zealand healthy aging strategies. Table 5 shows an example of such a matrix, with potential initiatives available in New Zealand.

Table . Recommendations for supporting older adults' well-being in regional communities.

Theme (4 Ss Framework)	Recommendation	Rationale/evidence
Services	Prioritize hybrid service models that combine digital and in-person delivery	Digital tools are useful but cannot replace in-person interaction; hybrid models improve access and support well-being
Support	Reenvisage community spaces as multifunctional hubs for digital training, service access, and social connection	Lack of digital skills and trust creates exclusion, training in familiar settings, builds confidence and inclusion
Spaces	Apply universal design to housing, public infrastructure, and transport	Universal design ensures accessibility; improved transport access enables participation, independence, and aging well in place
Social connection	Establish well-being navigator roles to support older adults in accessing services	Limited trust in technology is a barrier; navigators build trust, reduce isolation, and strengthen community networks

Table . Proposed matrix for wellness interventions, with some examples.

Examples of wellness interventions	Services	Skills	Spaces	Social connectedness
Physical health/te taha tinana	Meals on wheels	Fitbits, waka ama	Gyms, safe pavements	Social prescribing
Spiritual health/te taha wairua (sense of meaning and purpose)	Older adults working with youth	Virtual reality journeys	Marae, museum	Kai Hub, Kapa haka
Mental or emotional health/te taha hinengaro	Well-being navigators	Mobile banking	Safe public gardens	Repair cafes and Menzshed
Family/te taha whānau (social well-being)	Free hearing aids	SeniorNet	Library	Skinny Jump, social media

Limitations

This study was based on a small regional population in New Zealand and relied on self-reported experiences, both of which are common limitations in focus group studies. The COVID-19 public health restrictions and national lockdowns at the time shaped recruitment and influenced preferences for individual interviews over group discussions, as well as limitations to completing documentation such as consent forms. As the number of individual interviews grew, fewer new ideas emerged; however, determining data saturation remains contentious, with varying definitions across qualitative research. Therefore, caution is required when applying the findings beyond the study location.

Future Research

Opportunities for further studies include testing the 4 Ss Framework in other settings, for example, with older adults with low vision examining postpandemic digital adoption and evaluating the effectiveness of social prescribing and well-being navigator roles in facilitating digital engagement. The authors are not qualified to speak on Te Ao Māori but suggest a closer exploration of how marae support, and can be supported, to enhance the well-being of Māori, and indeed other Indigenous peoples, recognizing not only the importance of maintaining tradition and belonging, but also as to how it can be applied to non-Māori and other non-Indigenous populations.

Conclusions

The future presents significant opportunities to enhance the well-being of older adults and communities through targeted, inclusive, and innovative approaches. Building on the thematic analysis and existing strategies, this study proposes a practical framework (the 4 Ss Framework) to guide future planning for age-friendly communities. As a methodology, the 4 Ss Framework provides a structured approach to anticipating the future well-being needs of older adults to support them to age well and age in place. By translating the lived experiences of older adults into an actionable framework, this study contributes to local and international efforts to create inclusive, resilient, and age-friendly communities. The 4 Ss Framework reflects the priorities of the WHO Global Network for AFCC, the UN Decade of Healthy Ageing, and OECD (Organisation for Economic Co-operation and Development) well-being agendas, offering a transferable approach designed as a tool to support and strengthen the future well-being of communities.

Abstract

Background: Older adults in affordable housing face heightened risks of social isolation and loneliness due to limited social networks, transportation barriers, chronic conditions, and inadequate technology access. Smart speakers offer potential for enhancing social connectedness in this underserved population, yet technology interventions are rarely designed with meaningful input from older adults themselves. User-centered design (UCD) approaches can address this gap by engaging end users throughout the development process to ensure technology solutions align with their needs and living contexts.

Objective: This study aimed to engage older adults in affordable housing in an iterative UCD process to develop prototype scenarios for smart speaker–based applications that promote social connectedness while addressing safety, community-building, and wellness needs.

Methods: We conducted a 3-stage UCD study with 29 older adults (mean age 70, SD 6.8 years; 23/29, 79% African American; 20/29, 69% high school education or less) living alone in affordable housing between April 2021 and April 2022. Stage 1 included 5 focus groups (n=25) combining needs assessment discussions with rapid brainstorming activities. Stage 2 involved research team synthesis of focus group transcripts and brainstorming data to create a Design Strategies Map, development of initial prototype scenarios, 5 evaluation focus groups (n=18) to gather feedback, and iterative scenario refinement. Stage 3 comprised 4 validation focus groups (n=17) to assess refined scenarios and identify implementation recommendations. Participants included both smart speaker users (n=13) and nonusers (n=16). Data were analyzed using thematic analysis for needs assessment, content analysis for brainstorming ideas and feedback, and matrix analysis for systematic comparison across scenarios.

Results: Participants generated 153 ideas for smart speaker use, with Health and Safety and Daily Assistance being the most frequent categories. Analysis revealed that social connection needs were inseparable from safety concerns related to living alone. Through iterative co-design, we developed 7 prototype scenarios across 4 functional categories: Checking-In (peer and management safety verification with privacy controls), Social Companion (conversational artificial intelligence–based companionship and emotional support), Community Involvement (virtual bulletin boards and activity coordination), and Wellness Check (system-initiated monitoring of activity and behavioral patterns as health indicators with user-controlled interventions). Participants emphasized requirements for personalization, opt-in/opt-out controls, “Do-Not-Disturb” functionality, and safeguards preventing replacement of human connection.

Conclusions: Older adults in affordable housing engaged in technology design and provided valuable insights that challenge assumptions about their needs and preferences. The prototype scenarios addressed the dual imperatives of social connection and safety while living alone, offering a foundation for developing technology-based applications tailored to underserved populations. Implementation should prioritize user control, privacy protection, and human-in-the-loop design ensuring that technology facilitates rather than replaces human connection and community programming, alongside consideration of user characteristics to build trust and ensure effective, sustained use of the intended technology platform.

Introduction

Background

Research has repeatedly demonstrated the critical importance of social connectedness in older age. Social isolation and loneliness, the main constructs of social disconnectedness, are prevalent in Americans aged 65 years and older, with prevalence rates approaching nearly 25% for the former [1] and ranging from 17% to 57% for the latter [2-4]. Social isolation is objectively defined as the lack of social contact, communications, and relationships [1,5], while loneliness refers to a subjective feeling resulting from a perceived deficit in the quantity or quality of meaningful social relationships [6]. Older adults who are socially isolated or feel lonely exhibit a wide range of negative health outcomes, including depression, cardiovascular diseases, poor cognitive function, reduced quality of life, and increased mortality [2,5,7,8].

Social isolation and loneliness are pressing concerns for older adults living in affordable housing (hereafter referred to as "residents") because they have limited social networks, transportation options, and access to information and communication technology (ICT) [9]. Chronic health conditions and disabilities are also common in this population [10,11], which affect their ability to establish and maintain meaningful social interactions. Also, affordable housing, particularly in high-rise structures, may lack communal areas [12] or discourage residents from inviting others over due to suboptimal building conditions [13]. The complex interplay of health, housing conditions, and social and financial factors may contribute to elevated levels of social isolation and loneliness among residents [14]. Innovative approaches are necessary to increase meaningful social connections and reduce loneliness in this population. It is recognized that there is no "one-size-fits-all" approach to address this issue and there is a need to design interventions customized to meet specific groups or the varying levels of social isolation and loneliness they may experience [15].

A notable gap exists in technology-based interventions tailored to enhance social connectedness among residents. While face-to-face programs and services for improving social connections are available for older adults (eg, community senior centers and senior cafés), these may be inaccessible to older adults residing alone in affordable housing for multiple reasons mentioned previously. The growing interest in voice-operated smart speakers (eg, Amazon Echo and Google Home) has increased an exploration into how this technology can enhance social connectedness in community-dwelling older adults [16-18]. The hands-free voice control may improve accessibility and usability for people with vision impairment, mobility limitation, or poor dexterity. Artificial intelligence (AI)–based voice agents (eg, Amazon Alexa) on smart speakers have the potential to help older adults in limited-resource settings feel less lonely and engage more in social activities, for example, by providing easy access to communicate with others. Studies provide preliminary evidence that older adults enjoy social health benefits from interactions with an AI voice agent, such as a source of companionship reducing loneliness and improving mental health [18,19].

Despite the potential benefits of smart speakers, unique challenges to their adoption and use may arise, particularly when the needs of target end users are overlooked or inadequately addressed. Moreover, historically marginalized communities, including low-income older adults and racial or ethnic minority groups, still face inequity in ICT access as well as challenges in its adoption and use [20-22]. Low ICT adoption and utilization are attributed to various barriers, including technology costs, internet accessibility, functional impairments, low literacy, lack of self-efficacy, privacy concerns, and mistrust of the technology [23-28]. Recognizing the unique needs of users and the factors influencing acceptance and usability within the user's living context is critical for implementing technology-based interventions. This can be accomplished through user-centered design (UCD), which involves exploring user needs, preferences, and technology requirements; engaging users throughout the design process; and iteratively developing technology prototypes [29].

Aims

The purpose of the study was to engage older adult residents living alone in affordable housing in an iterative UCD process to develop prototype ideas of innovative solutions leveraging smart speaker technology for social connectedness. Through a 3-stage co-design process, we sought to (1) understand the social connection needs and technology preferences of residents, (2) collaboratively develop and refine prototype scenarios that address these needs, and (3) identify design requirements and implementation considerations for future deployment. Our work focused on *early* prototyping to develop technology solutions and build a shared understanding of the social connection needs in this population. Our long-term goal is to develop smart speaker–based applications called *Voice2Connect* for deployment in affordable housing to enhance social connectedness among their residents.

Methods

Study Design

We conducted a UCD study to engage residents in developing smart speaker–based applications for social connectedness. Our process consisted of three major stages conducted between April 2021 and April 2022: (1) needs assessment and idea generation, (2) iterative prototype development, and (3) validation and implementation planning (Table 1).

XSL•FO
RenderX

Table . Study design overview.

Stage and phases	Activities	Participants	Key outcomes
Stage 1: Needs assessment			
Phase 1	• Focus group discussions • Video introduction to smart speakers • 6-8-5 brainstorming exercise • Pictorial sheet ideation	25 older adults (5 groups; 12 users and 13 nonusers)	• Social connection needs • 153 design ideas • User requirements
Stage 2: Iterative development			
Phase 2	• Team synthesis of phase 1 data • Design Strategies Map creation • Initial scenario development	Research team	• 4 functional categories • 7 initial scenarios
Phase 3	• Scenario presentations via role-play • Feedback focus groups	18 older adults (5 focus groups; 8 users and 10 nonusers)	• Design preferences • Concerns identified • Improvement suggestions
Phase 4	• Matrix analysis of feedback • Scenario refinement	Research team	• 7 refined scenarios
Stage 3: Validation			
Phase 5	• Refined scenario presentations • Validation focus groups • Implementation planning	17 older adults (4 groups; 5 users and 12 nonusers)	• Validated prototypes • Deployment recommendations

Setting and Participants

We recruited participants from 3 housing buildings in Richmond, Virginia, United States (referred to as housing A, B, and C) that serve older adults with limited income and individuals with disabilities. Our research team had established relationships with these communities through prior collaborative research and wellness programs. Eligible participants were older than 55 years, lived alone, could speak and understand English, and were able to participate in all study activities. We excluded individuals with severe sensory impairments preventing engagement with audiovisual materials, terminal illness, or a score ≤8 on a short version of the Montreal Cognitive Assessment indicating moderate to severe cognitive impairment. Participants were divided into 2 groups based on smart speaker experience: users (n=13) who had been using Amazon Echo Dot devices deployed by housing A since January 2020, and nonusers (n=16) from all 3 housing sites.

We recruited participants through multiple channels including housing management referrals, community wellness program participant lists, on-site information sessions, and flyers. Due to pandemic-related visitor restrictions, eligibility screening was conducted by phone, during which we also collected demographic and technology experience information. Detailed descriptions of recruitment procedures can be found elsewhere [30].

Ethical Considerations

The Institutional Review Board of Virginia Commonwealth University determined that this project posed minimal risk and waived written informed consent (HM20020008).

Procedures

We conducted focus groups with older adults in phases 1, 3, and 5 to perform an iterative co-design process and gather data. The groups were stratified by housing building and current smart speaker use (Table 2).

[a]One nonuser resident from building A attended this meeting.

Stage 1: Needs Assessment and Idea Generation (Phase 1)

We conducted 5 focus groups (n=25) between April and July 2021. Due to pandemic restrictions, we held the first 3 meetings in a campus lecture room, providing van transportation since most participants lacked reliable transportation. Safety protocols included temperature checks and mask requirements.

Each 1 - to 1.5-hour session consisted of 2 parts. First, we explored participants' needs for establishing and maintaining meaningful social contacts and their desired outcomes from smart speakers. To help nonusers understand the technology, we presented a 5-minute video demonstrating basic smart speaker tasks (weather checking, drop-in calls, and dictionary functions). Second, we facilitated rapid brainstorming using the 6-8-5 design method [31], where participants generated 6 - 8 ideas in 5 minutes. Participants worked in mini groups of 2 - 3 with a facilitator, sharing ideas and asking clarifying questions. We used pictorial sheets (Multimedia Appendix 1) where participants articulated specific social connectedness tasks they wanted to accomplish using smart speakers. After 2 brainstorming rounds, mini groups presented key ideas to the larger group. Audio-recorded sessions were transcribed verbatim and analyzed as described in the Data Analysis section.

Stage 2: Iterative Prototype Development (Phases 2-4)

Phase 2: Initial Scenario Development

The research team synthesized phase 1 data through multiple team meetings, creating a Design Strategies Map that linked user needs with potential smart speaker–based solutions. Through triangulation of focus group data and pictorial sheet ideas, we identified 4 main functional categories: checking-in, social companion, community involvement, and wellness check. We developed 1 - 2 scenarios within each category—short stories depicting user characteristics, context of use, and specific technology-based tasks to achieve goals [32,33]. Scenarios incorporated voice interactions with "Alexa" and were written at a third-grade reading level to ensure readability and accessibility.

Phase 3: Evaluation Focus Groups

We conducted 5 focus groups (n=18) in October 2021, presenting initial scenarios through role-play demonstrations by 2 team members. After each scenario, we solicited feedback on design perceptions, willingness to use, improvement suggestions, and concerns.

Phase 4: Scenario Refinement

Phase 3 focus group recordings were transcribed verbatim and analyzed as described in the Data Analysis section. We identified key suggestions for each scenario and revised prototypes accordingly.

Stage 3: Validation and Implementation Planning (Phase 5)

We conducted 4 focus groups (n=17) in April 2022 to validate refined scenarios. Team members again used role-play to present scenarios, explicitly noting incorporation of previous feedback. We solicited perceptions, desired additional features, and implementation recommendations. Sessions were transcribed verbatim and analyzed as described in the Data Analysis section. Throughout the study, participants received US $20 gift cards at each session. Focus groups were limited to 6 participants to

XSL•FO
RenderX

encourage initiated conversations while minimizing groupthink [34].

Measures

Before phase 1, we conducted a phone-based survey to collect data on demographics, technology experience, social well-being (social isolation, loneliness, and satisfaction with current social interaction levels; Multimedia Appendix 2), and other aspects of health such as functional status, depression, sleep, and physical activity. This manuscript reports only on demographics, technology experience, and social well-being.

Data Analysis

We used a combination of inductive and deductive qualitative approaches across the 3 stages of the UCD process, selected to match the analytic goals of each phase (Table 3).

Table . Focus group data analytic approach.

Stage	Phase	Analytic approach
Stage 1	Phase 1	Inductive thematic analysis; content analysis of pictorial sheets
Stage 2	Phases 3 - 4	Deductive content analysis; matrix display
Stage 3	Phase 5	Deductive content analysis

Phase 1 (Needs Assessment)

Three team members conducted inductive thematic analysis [35] of focus group transcripts to explore participants' social connection needs and identify user preferences for low-fidelity prototype development. Transcripts were imported into Atlas.ti (Lumivero, LLC) software for coding. They independently reviewed transcripts multiple times and met to discuss how participants wanted to use smart speakers for social connectedness and general well-being. These preliminary ideas became codes (eg, how to stay in contact, feeling lonely or isolated, and user needs and preferences), forming the basis for an initial codebook that included code definitions. The team had regular meetings to discuss coding and listed all design ideas mentioned by participants and relevant quotes. We used Miro for affinity mapping to cluster ideas into emergent categories. Rigor strategies included collaborative coding with consensus discussion, peer debriefing with external stakeholders, an audit trail of analytic decisions, and rich description with illustrative quotes. Detailed user challenges with voice user interface on smart speakers and social isolation and loneliness experiences among these participants are published elsewhere [36].

We conducted a content analysis [37,38] of pictorial sheet data using a deductively developed coding framework of 8 categories: daily assistance, health and safety, socializing with others, learning, companionship with a voice agent, entertainment, religion, and miscellaneous. One researcher (NM) assigned category labels to all ideas, which were subsequently reviewed and validated by another researcher (JC). They reconciled any discrepancies through a team discussion, after which the total number of smart speaker–based tasks for each category was calculated.

Phases 3 - 4 (Prototype Evaluation and Refinement)

Two researchers (JC and NM) independently conducted deductive content analysis [37] of phase 3 focus group transcripts using the 4 functional categories established in phase 2 as an organizing framework. A matrix display approach [39] was used to systematically arrange findings by domain, enabling efficient comparison of design preferences and recommendations across focus groups [40]. They (JC and NM) read transcripts multiple times and made notes independently in a pre-agreed template. Then they compared their coding results and reconciled any discrepancies. Based on this discussion, they identified key suggestions for each scenario, presented these to the whole team to get feedback, and then made refinements to the prototype scenarios.

Phase 5 (Validation)

Two team members analyzed transcripts following the phase 4 approach, using deductive content analysis to identify themes relevant to system deployment and implementation planning.

Results

Participant Characteristics

Twenty-nine older adults participated in 1 or more focus group sessions (Table 4). The sample was predominantly African American (n=23, 79%), with 55% (n=16) male. Out of 29 participants, 20 (69%) participants had completed high school education or less. While 21 (72%) participants owned smartphones, only 15 (52%) participants had computer or laptop access, and 12 (41%) participants had never used the internet. Thirteen (45%) participants were smart speaker users at study inception, 11 (85%) of whom reported prior internet use and 2 (15.4%) did not. Among the 11 participants with prior internet use, the majority (n=8, 73%) were daily internet users.

Somewhat dissatisfied	3 (10.3)
Satisfied	16 (55.2)

[a]LSNS-6: Lubben Social Network Scale-6 items.

[b]UCLA: University of California, Los Angeles.

At baseline, participants had a mean Lubben Social Network Scale-6 score of 15 (SD 6.7), with 8 (28%) out of 29 participants meeting the threshold for social isolation (Lubben Social Network Scale-6 score of <12). Mean University of California, Los Angeles (UCLA) Loneliness Scale-Short Form score was 4.6 (SD 1.9), with 9 (31%) out of 29 participants meeting the threshold for loneliness (UCLA Loneliness Scale-3 ≥6). While just over half of the participants (16/29, 55%) reported being satisfied with their current social relationships, 34% (10/29) reported being very dissatisfied and 10% (3/29) somewhat

XSL•FO
RenderX

dissatisfied, and fewer than half (12/29, 41%) reported participating in any organizations, religious groups, or committees.

Stage 1: Understanding Social Connection Needs and Generating Ideas

Social Connection Context and Needs

Focus group discussions revealed multiple factors driving the need for enhanced social connections among residents. Participants described how the pandemic disrupted existing social ties, leaving many feeling isolated. They expressed willingness to help fellow residents experiencing isolation but lacked mechanisms to do so. Many had restricted social networks in general due to limited transportation, mobility constraints, and inadequate access to information about community activities. A critical finding was that participants' social connection needs were inseparable from safety and survival concerns related to living alone. As one participant explained:

> *That would be the best thing we need for Alexa to do. To let everybody—where everybody can say I'm okay, or they check in. Somebody from the office or somebody calls and checks on everybody.* [Group 1, smart speaker user]

Participants emphasized that unexpected health events were a constant worry, creating a need for check-in systems that went beyond traditional socialization support.

Brainstormed Design Ideas

Twenty-four participants generated 153 ideas on pictorial sheets (Multimedia Appendices 3 and 4), with individual contributions ranging from 1 to 16 ideas. The mean number of ideas developed by smart speaker users and nonusers was similar (users: mean 6.6, SD 3.8; nonusers: mean 6.2, SD 5.2). The most frequent categories were Daily Assistance (n=41, 26.8%) and Health and Safety (n=34, 22.2%). Social connectedness generated 35 total ideas across 2 categories: Socializing With Others (n=26, 17.0%) and Companionship With Virtual Agent Alexa (n=9, 5.9%). Additional categories included Learning (n=28, 18.3%), Entertainment (n=7, 4.6%), Religion (n=3, 2.0%), and Miscellaneous (n=5, 3.3%) purposes. Examples of social connection ideas included: "Talk to other residents" and "Call my daughter," "Alexa could call my friends and tell my friends I said hi, and tell them to call me," "Help me check on my health...If I'm feeling a certain way, tell me what you think is wrong," and "What if there was a way to send out a message saying, 'I'm going to go walk. Anyone want to go walk with me?'"

Stage 2: Co-Designing Smart Speaker–Based Applications for Social Connectedness

From User Needs to Design Principles

Through synthesis of focus group transcripts and pictorial sheet data, we developed a Design Strategies Map (Table 5). This analysis revealed overarching design principles: (1) the system should support both social connections and safety while living independently, (2) the system should help build stronger community cohesion, and (3) the design should recognize differing needs across individuals and housing contexts. These principles guided development of 4 functional categories with specific use cases designed to address the social-living context of affordable housing residents aging alone (Multimedia Appendix 5).

XSL•FO
RenderX

Table . Design Strategies Map linking older adults' needs to smart speaker–based application[a].

User need theme	Illustrative quotes	Design response
Safety and Emergency Support While Living Alone	• "That would be the best thing we need for Alexa to do...where everybody can say I'm okay, or they check in. Somebody from the office or somebody calls and checks on everybody." [User, Group 1] • "If we had Alexa, (we could say) 'Alexa, I feel like I'm gonna fall out. Send 911.' A lot of people here have nobody they can talk to." [Nonuser, Group 5]	Checking-in function • Peer-to-peer wellness checks • Management check-in programs • Emergency contact system • Reminders to connect with others
Companionship and Emotional Support	• "It'd be nice if I could have something to talk back to me." [User, Group 2] • "Sometimes I felt down, and I talked to Alexa, and she gave me some good answers... when I'm lonely, that's for sure." (Nonuser, Group 3) • "It could help you—if you're a person with depression and anxiety, you could talk to Alexa to have some company. That would help you have company—have somebody to talk to. Especially if you don't come out and get no fresh air or walk nowhere, where you take walks and see people and speak to them." [Nonuser, Group 4) • "You would need somebody to talk to. Can Alexa read books?" [Nonuser, Group 5]	Social companion function • Conversational AI[b] for daily interaction • Positive affirmations and greetings • Conversational AI reading books aloud to user and encouraging discussions • Recall of past conversations
Community Connection and Social Participation	• "What if there was a way to send out a message saying, 'I'm going to go walk. Anyone want to go walk with me?...You might decide to go, right?" [User, Group 1] • "Alexa could call my friends and tell my friends I said hi, and tell them to call me." [Nonuser, Group 4] • "Keeps me in touch with my daughter." [Nonuser, Group 5] • "That would be helpful to me if it will remind me to call my mom." [Nonuser, Group 5] • "I don't want to just think this [building] is where I'm gonna die at...[We] want something lively." [Nonuser, Group 5]	Community involvement function • Virtual bulletin board for events • Coordination of group activities • Information about local resources • Facilitation of meetups and outings
Health Monitoring and Wellness Support	• "Help me check on my health, such as my temperature, blood pressure....If I'm feeling a certain way, tell me what you think is wrong." [Nonuser, Group 3]	Wellness check function • Integration with wearables • Activity pattern monitoring • Mood and loneliness detection • Prompts for intervention

[a]These ideas were identified through phase 1 focus groups and brainstorming activities. Design responses represent the 4 functional categories developed for prototype scenarios.

[b]AI: artificial intelligence.

Four Functional Categories of Smart Speaker–Based Applications

Category 1: Checking-In (2 Scenarios)

Participants identified checking-in as the most important feature. This included both peer-to-peer and management-to-resident check-ins to address living-alone concerns and emergency support needs, focusing on confirming that a resident is present and safe. As one participant noted: "A lot of people here have nobody they can talk to" [Group 5, nonuser]. The scenarios enabled residents to connect with neighbors through voice commands and established opt-in check-in programs with housing management.

Category 2: Social Companion (2 Scenarios)

Conversational AI could offer companionship, emotional support, and continuity by recalling past interactions. Participants recognized that this could help residents feel less lonely: "Sometimes I felt down, and I talked to Alexa, and she gave me some good answers...when I'm lonely, that's for sure"

XSL•FO
RenderX

[Group 3, nonuser]. Scenarios depicted personalized interactions where Alexa engaged in book discussions and daily conversations with residents.

Category 3: Community Involvement (2 Scenarios)

The technology could facilitate participation by sharing local information (eg, bus routes and community events), enabling virtual gatherings, or arranging meetups. Participants wanted to build "something lively" rather than viewing their housing as purely a place to age in isolation. Scenarios included virtual bulletin boards for community activities and coordinated group trips to essential destinations. Housing providers' role was assumed to coordinate and manage these programs while Alexa's role was access facilitation.

Category 4: Wellness Check (1 Scenario)

Integration with activity tracking devices such as fitness bands capable of monitoring movement, sleep, and inactivity could enable system-initiated health monitoring that detects changes in activity levels as potential signals of physical and emotional health status, prompting the user toward individual action or connection with others (eg, health care providers and significant others). This scenario assumed that participants would have access to such devices, which would communicate activity data to the smart speaker. We developed 7 initial scenarios across these categories based on iterative refinements based on team review (Multimedia Appendix 6), written at accessible reading levels and featuring familiar names to enhance relatability.

Refining Prototypes Through User Feedback

Phase 3 evaluation revealed both enthusiasm and concerns. Participants appreciated applications that could foster connection and help them stay informed about housing events. They strongly preferred technology facilitating human connection over purely automated interactions. The social companion features were seen as useful for those experiencing loneliness, although some worried about replacing rather than supplementing human contact.

Privacy and obtrusiveness emerged as primary concerns. Participants worried about other residents or management checking-in at any time, unintentional sharing of location and activity information, and technology exerting excessive control (described as "too Orwellian" by one group). Responses to the wellness check scenario indicated that participants were receptive to the use of wearable-based data for monitoring physical inactivity and detecting potential falls. However, they expressed a clear preference for systems that prompt rather than diagnose, flagging activity changes and facilitating human connection, rather than inferring emotional states from sensor data.

Participants provided concrete improvement suggestions for each scenario (Multimedia Appendix 7). In summary, these include (1) user control—add "do-not-disturb" features and allow selection of check-in frequencies, (2) privacy protection—create close contact lists rather than building-wide access and ensure that health information is not shared during check-ins, (3) natural interaction—make voice interfaces sound conversational rather than mechanical, (4) minimal management oversight—limit housing management role to essential check-ins only, and (5) personalization options—allow users to set speaking times, choose conversation perspectives, and toggle features on/off.

The depth and quality of participant contributions did not differ by prior smart speaker experience. Analysis of focus group interviews across all 7 design scenarios revealed comparable levels of engagement between smart speaker users and nonusers. Per focus group, both groups generated similar numbers of positive themes (users: 11; nonusers: 11) and design recommendations (users: 14; nonusers: 11.3). The major design themes, including privacy and user control, perceived usefulness for socially isolated residents, trusted contact network preferences, and voice-based security, emerged consistently across both groups. While users occasionally drew on their lived device experience, nonusers contributed equally substantive and actionable recommendations, including novel suggestions such as video interfaces for hearing-impaired residents, information integration, and peer activity coordination via Alexa.

Based on this feedback, we revised all 7 scenarios (Textbox 1). Key changes included adding opt-in or opt-out capabilities, do-not-disturb functions, contact list controls, and explicit privacy protections. For example, in the management check-in scenario, we specified that Alexa would confirm resident status without sharing additional details the resident mentioned (eg, having a cold). Figure 1 shows a graphic representation of a scenario in the checking-in category.

XSL•FO
RenderX

Textbox 1. Refined scenarios of use for the Voice2Connect system prototypes. Italicized text shows the changes made based on the feedback from phase 3 focus groups.

Category 1: Checking-in

Scenario 1: Using Alexa to talk to your neighbor or friend

Tom, 78-year-old man, uses the smart speaker to check in on others in the building. Tom has not heard from or seen his neighbor Jeanne in 2 weeks, but he knows that Jeanne also has an Alexa Dot, and *he and Jeanne have added one another to their contact lists*. So he speaks to Alexa to see whether Jeanne is doing well: "Alexa, connect me to Jeanne" and then he is connected to Jeanne. Tom asks Jeanne, "Hey, how are you doing? I just want to make sure you are well." Tom and Jeanne chat briefly through the speaker to share what is going on with them. Two days later, Tom is watching TV and *he doesn't want to get bothered, so he turns on the Do Not Disturb Feature. When Jeanne tries to contact him, there is an auto-message from Alexa:* "Tom has turned on 'Do Not Disturb.'"

Scenario 2: Check-ins from the management

The building management started a resident check-in program through Alexa. Cathy opted into the wellness check-in service, and she chose management daily check-ins. Tom also opted into the check-in service and he chose weekly check-ins. The office manager put an announcement on the Alexa of check-in program participants in the building: "Hi Cathy, how are you? This is management. Please tell Alexa if you are ok. If we do not hear from you in 24 hours, we will come to your apartment to check on you." Cathy said, "Alexa, tell management I am ok. I have had a bad cold recently." Alexa informs the management that Cathy is okay and *doesn't say anything about Cathy's bad cold*.

Category 2: Social companion

Scenario 1: Being a friend with Alexa

George is a widowed 85-year-old man and lives alone. *He wants to have an individualized interaction with Alexa, so he chooses the highest level of personalization*. George's children come and visit him on the weekends, but during the week he has little social interaction and often feels lonely. Alexa detects when George gets out of bed and greets him by saying "Good Morning, George, how did you sleep?" George replies saying, "I slept well. Alexa, can you read me the next chapter of my Steven King book at 10 am?" At 10 AM, Alexa says, "Here is where we left off reading yesterday" and continues to read the book aloud to George. After some time, George says, "Alexa, stop reading. This book is getting very good." Alexa replies, "It is. What do you think is going to happen next?" George replies, and Alexa says, "That is possible, we should read again tomorrow."

Scenario 2: Conversation between you and Alexa

John has arthritis in his knees and hips, making walking and standing for long amounts of time painful for him, so he likes to stay at home most of the time. Getting out in the community and connecting with other people has been difficult because of John's limited mobility. John likes to talk to Alexa. In the mornings he will say "Good morning, Alexa," and Alexa will reply, "Good morning, John. Today is going to be a blessed day." John is able to reply, "Every day is a blessed day."

John likes to talk out loud about what is happening in his favorite television show and movies. Alexa remembers what John says is happening in the movie and is able to talk with him about it. "John, that is a popular movie. Online it has hundreds of 5-star reviews. One person left a review and said 'this is one of my favorite movies. I was not a big fan of the ending, but overall the plot was good,'" "Alexa, I agree, but it was still a good movie."

Category 3: Social participation

Scenario 1: Getting involved in the community

Alice, a 75-year-old woman, recently moved into a new apartment building to be closer to her children. *Alice wants to make new friends in the building, so she has opted into the community events bulletin board. When Alice comes home from the grocery store, she sees a light on her Alexa, telling her there is an announcement. Alice asks Alexa,* "Alexa, what is the announcement?" *Alexa says,* "There is a Spanish class today at 3 pm. Would you like to hear other activities happening today?*" Alice says,* "yes, please," *and Alexa reads Alice the list of community activities. Alice says,* "Alexa I think I want to try that Spanish class. Remind me when it is time." *Later at 2:50 PM, Alexa says,* "Don't forget, Spanish class starts in 10 minutes." On Sunday, Alexa says to Alice "Good morning Alice, there is the weekly church service going on in the community room downstairs. Everyone in the building is invited."

Scenario 2: Meetups

David is a new resident of affordable senior housing and recently got an Alexa. After settling into his new apartment, *he opted in to a virtual bulletin board to see what events are happening in the building. David asks Alexa,* "Is there any activity going on today?*"* Alexa says, "John and Martha will walk to a park at 3 pm today for exercise. Do you want to join?" David says, "Yes, put me on the list." *Alexa reminds David 30 minutes before,* "David, you will need to meet them at the entrance at 3 pm."

A couple of days later, David made a list of grocery items he needed. Being new to Richmond, David did not feel comfortable going alone. He said, "Alexa, can you ask if anyone needs to go to Kroger today? We can all take the bus together. *Also, add this to the virtual bulletin board so other people know about this*." Alexa replies, "Martha will go to Kroger with you today at 2 pm. You can take the #3 bus at 1:30. It will pick you up in front of the building."

Category 4: Wellness check and mood detection

Scenario 1: Mood detection

XSL•FO
RenderX

Paula, a 69-year-old woman, has been living in her apartment building for 4 years. She would describe herself as fairly active and social with a few good friends living in the same apartment building. Recently, her only child and grandchildren moved further away from Paula, making it more difficult to see each other. *Paula is worried about becoming lonely, so she opts into the loneliness detection feature*. A few weeks later, Paula is seeing her friends less frequently, sleeping in later, taking naps, and is spending more time watching TV. Alexa says "Paula, the data from the Fitbit tell that you have not been as active as you normally are. How are you doing? Would you like me to connect you with one of your friends or your doctor?" *Paula says*, "Well, Alexa, I don't think I need the doctor, but I haven't been very active recently and am feeling a little lonely." Three days later, Paula still has not left her apartment. *Alexa says*, "Paula, you still seem to be less active than usual. Would you like me to connect to your friend or read the list of activities on the bulletin board?" *Paula agrees, and Alexa connects Paula to her friend to make plans for a walk*.

Figure 1. A graphic representation of a Voice2Connect prototype in the checking-in category. This figure shows verbal interactions between user and voice agent.

Stage 3: Validating Final Prototypes and Planning Implementation

Overview

Participants expressed varied but generally positive opinions about refined scenarios. Overall, they appreciated the vision of using smart speakers to foster a more connected and livable community, although enthusiasm varied by scenario. Features requiring movement or mood detection to identify emotional health risks were viewed most skeptically, with concerns about excessive technological control over daily life.

XSL•FO
RenderX

Crosscutting Themes From Validation Sessions

Personalization as Essential

Participants emphasized the importance of controlling features rather than having a one-size-fits-all system. Suggestions included setting specific times for Alexa to speak, choosing conversation styles or perspectives (eg, "Christian perspective"), and selecting which physiological metrics to monitor.

Safety Remains Paramount

Across nearly all scenarios, participants referenced potential health emergencies, particularly for residents in poorer health or facing adverse outcomes. The checking-in and wellness check functions were especially valued. As one participant noted, "That's better than somebody knocking on your door to see if you're okay" [Group 4].

Preventing Replacement of Human Connection

Participants stressed the need for safeguards against AI technology replacing human interaction or enabling abusive behaviors. They wanted technology that facilitated human connection rather than substituted for it.

Discussion

Principal Findings

This study used an iterative UCD process to engage older adult residents in affordable housing in designing prototype scenarios for smart speaker–based applications to promote social connectedness. Throughout 3 stages of co-design, we developed 7 scenarios across four functional categories: (1) checking-in for safety verification, (2) conversational AI as social companions, (3) community involvement, and (4) wellness monitoring. These scenarios provide a foundation for developing a technology platform tailored to address the specific social isolation and loneliness experienced by underserved older adult populations, who often face distinct challenges in locating and accessing the social and financial resources necessary for aging in place. Baseline social well-being data underscore this need. While more than half reported satisfaction with their current social relationships, a meaningful subgroup was experiencing clinically significant loneliness and social isolation, lending ecological validity to their strong interest in features supporting social connectedness in their living communities.

The findings of this study can be interpreted through the lens of Self-Determination Theory [41], which posits that human motivation and well-being are grounded in 3 psychological needs: autonomy, competence, and relatedness. Self-Determination Theory maps meaningfully onto the design preferences and concerns expressed by participants across all phases. The demand for customization, opt-in controls, do-not-disturb features, and close contact lists reflects a fundamental need for *autonomy*, the desire to maintain personal agency over one's social environment and information sharing. Participants' requests for interfaces that are simple, conversational, and responsive to their voice reflect the need for *competence*, the ability to engage effectively with technology without feeling overwhelmed or excluded. Finally, participants' desire for building a livable community for themselves and peers and for preserving human relationships in the loop reflects the need for *relatedness*, belongingness, and meaningful connection with others. Designing smart speaker–based applications that satisfy these needs may be essential not only for usability but for sustaining intrinsic motivation for continued technology engagement and well-being outcomes in this population.

Social Connectedness Inseparable From Safety and Survival

Throughout the design process, it became clear that the study's focus on social connectedness strongly resonated with participants due in part to the isolation they experienced during the COVID-19 pandemic, a period during which residents faced significant restrictions on in-person social interaction. The strong participant interest in peer check-ins and community engagement features may partly reflect this context, and it is plausible that the relative prioritization of these features could differ in a postpandemic sample. Importantly, however, a critical insight emerged: for affordable housing residents living alone, social connection needs cannot be separated from safety and survival concerns. Participants emphasized that any technology system must address both relationship-building and emergency support, reflecting the reality that all residents live alone and some face immediate safety vulnerabilities, including declining health and fall risk, that may arise at times when human assistance is not immediately available.

This dual emphasis shaped our design approach fundamentally. Rather than creating purely social applications, we prioritized checking-in functionality that serves both social and safety purposes. This finding aligns with research suggesting that older adults' technology adoption is strongly influenced by whether innovations address their most pressing daily concerns [42]. This study shows that for affordable housing residents with limited support networks, safety vulnerabilities are not abstract future concerns but immediate realities shaping their daily experiences of living alone [43].

Building Social Infrastructure in Affordable Housing

Our findings indicate that residents were genuinely interested in making a livable community within their housing by building social infrastructure [44], not just to address social needs but also to promote safe, independent living. Participants suggested various ideas, including virtually connecting with individuals in need, conducting remote safety check-ins, advertising community events, and facilitating coordinated trips to essential destinations (eg, grocery stores). Participants were interested in expanding and enhancing social networks within and beyond their housing community. Research suggests that digital tools connecting older adults to existing social networks may not significantly increase social activity for individuals lacking networks and at risk of social isolation [45]. However, tools designed to facilitate new social connections or broaden access to community resources can play a critical role in addressing these gaps [46]. Our scenarios address this through community-building features (eg, virtual bulletin boards, coordinated meetups, and shared activity planning) that help residents discover and connect with neighbors who share similar needs and interests.

XSL•FO
RenderX

The emphasis on community involvement also reflects participants' recognition that their housing buildings could become more than just places to live in isolation. They wanted technology that would help them build "something lively," a community with regular interaction, mutual support, and shared activities. This vision extends beyond typical conceptualizations of smart speakers as individual assistive devices and positions them as one component of a broader, community support ecosystem that can facilitate communication about opportunities and access to them, while the core work of building and sustaining community remains a fundamentally human endeavor. Importantly, technology alone is insufficient to establish such infrastructure. The foundation must be built through human-centered programming, dedicated staffing, and sustained relational investment. Smart speaker–based applications, therefore, should be understood not as substitutes for this work but as complementary tools that facilitate awareness of and access to existing and emerging community resources, functioning as bridges to human connection.

Engaging Underserved Communities in Technology Design

To our knowledge, this is one of few studies using UCD with older adults of lower socioeconomic status. Such populations are often excluded from design and testing processes for new technologies conceptualized to improve quality of life and health [47], probably due to concerns about their ability to engage meaningfully and provide valuable input. Limited access to ICT and low digital literacy also may have contributed to the underrepresentation of these communities in technology research and design initiatives. The limited participation of marginalized communities perpetuates the exclusion of their perspectives [48] and contributes to disparities in digital health access and outcomes. Given that widespread digital technology access has created new opportunities for self-management, quality of life, and social well-being in older adults [49-51], recognizing the importance of engaging community members of underrepresented populations in a technology development and testing process is essential.

Our study demonstrates that older adults in underserved communities, including those with limited prior technology experience, can actively participate in and meaningfully contribute to technology design processes. Our participants across age groups, technology experience levels, and housing communities demonstrated enthusiasm and active engagement and expressed a sense of ownership in the design sessions, contributing valuable insights that shaped prototype development. The 153 ideas generated during brainstorming activities, the nuanced feedback on privacy and control features, and the concrete implementation recommendations all demonstrate that concerns about this population's ability to engage in design work are unfounded.

Methodological Contributions: Adapting UCD for Underserved Communities

Our research has methodological implications for UCD research with and for underserved communities. The 3-stage iterative approach we used successfully balanced rigorous design principles with the unique contexts and abilities of participants. Our inclusive methods included rapid brainstorming sessions, facilitated mini-group discussions to ensure that everyone had a voice and that discussions remained focused and productive, audiovisual materials to enhance nonusers' understanding of the target technology and stimulate idea generation, scenario creation and role-play demonstrations to reduce uncertainty about the technology and facilitate discussions around privacy and security, and iterative design revision informed by continuous feedback.

These methods were thoughtfully chosen based on the literature [31-33] and the team's extensive experience working with affordable housing communities. Beyond specific UCD techniques, the team prioritized creating a comfortable, nonjudgmental environment where participants, especially those not familiar with smart speakers, could freely propose ideas, suggest changes to scenarios, and identify concerning features. We found that using pictorial sheets allowed participants with varying literacy levels to express ideas, while mini-group formats prevented more vocal participants from dominating discussions.

This study also demonstrates the need for flexibility in balancing rigorous design principles with the unique contexts and abilities of participants, as previous research demonstrated [32]. For example, during phase 1, we opted not to conduct mini-group sessions with focus group 5 (nonusers) after observing their difficulty engaging in technology-related discussions. Instead, we adapted our approach to facilitate a large group discussion focused on preferred functionalities for social connectedness, emphasizing their role as co-designers. This adaptive method adds important considerations specific to a UCD process with underserved populations, suggesting that methodological fidelity should sometimes yield to participant comfort and authentic engagement.

The established trust relationships our research team had developed through prior community-engaged work [52] proved essential to recruitment and retention. This suggests that successful UCD with marginalized communities requires sustained institutional commitment beyond individual research projects, and researchers cannot parachute in for design sessions without prior relationship-building and expect meaningful engagement.

Privacy, Control, and Trust as Essential Design Requirements

Participants' privacy concerns emerged consistently across all 3 stages and shaped significant design revisions. Their worries about unintentional information sharing, management surveillance, and loss of autonomy led to specific requirements: opt-in or opt-out controls, do-not-disturb features, close contact lists rather than building-wide access, and explicit privacy protections ensuring that sensitive information would not be shared with management or other residents. These concerns reflect broader issues of power, trust, and control that are particularly salient for minority, low-income older adults who may have experienced systemic marginalization and surveillance [53]. The description of mood detection features as "too Orwellian" signals deep discomfort with technologies that could exert control over their lives without consent. Our design

XSL•FO
RenderX

iterations directly addressed these concerns by centering user control and transparency.

Importantly, participants distinguished between features they found helpful (checking-in on neighbors and being reminded to connect with others) and those they found intrusive (automatic mood detection and unrestricted management access). This nuanced feedback demonstrates why participatory design is essential because researchers and technologists might assume that more automated, comprehensive monitoring would be beneficial, while users clearly articulated the need for boundaries and personal agency.

Balancing Human Connection and Technological Companionship

Participants expressed interest in voice agent companionship while simultaneously voicing concerns about replacing human interaction. This tension reflects broader societal questions about the role of AI in addressing loneliness and social isolation. Participants recognized that for those experiencing severe isolation, having "somebody to talk to" through Alexa might be "better than nothing," while also insisting on the primacy of human relationships.

Our scenarios attempted to navigate this tension by positioning voice agents as facilitators of human connection rather than replacements for it. For example, the social companion scenarios included Alexa suggesting the user connect with friends for walks rather than only offering its own companionship. The wellness check scenario prompted connection to friends or health care providers rather than only providing automated support. This design approach aligns with emerging ethical frameworks for AI companionship that emphasize augmentation rather than substitution [18]. However, participants' concerns suggest that implementation will require careful monitoring to prevent vulnerable, isolated individuals from becoming overly reliant on AI interaction at the expense of human relationships. Future development should include safeguards that encourage and facilitate human connection rather than allowing AI to become the primary or sole social contact.

Implementation Considerations and Future Directions

The varying levels of enthusiasm across scenarios suggest that a modular, customizable system would be most appropriate. Rather than implementing all 7 scenarios uniformly, housing communities should be able to select and configure features based on resident preferences, building infrastructure, and management capacity. This aligns with participants' emphasis on personalization and control. Moreover, given participants' limited experience with ICT and struggles with voice user interface interactions shared in phase 1 focus groups [11], resident training sessions and ongoing technical support are required for successful implementation. These supports are inherently service-oriented, requiring dedicated staff, sustained resourcing, and the cultivation of trust with residents, and should be considered alongside, rather than assumed to be fully addressed by the technology itself.

In the future, research should examine how smart speaker–based social connection tools interact with other community resources and interventions. Our participants identified transportation barriers, lack of information about community activities, and limited social networks as interconnected challenges. Technology solutions are most likely to succeed when integrated into broader community-based approaches that address structural barriers to social connection.

Learning emerged as a prominent brainstorming category in phase 1, comparable in volume to Socializing With Others. Participants—all nonusers—generated ideas spanning news and current events, language acquisition, practical skills, and digital literacy. Although this domain falls outside the social connectedness focus of this study, these observations point to an interest in intellectual engagement within this population, consistent with a growing literature on lifelong learning in older adults [54,55]. Future work might more explicitly examine learning-oriented smart speaker–based applications as a complementary pathway for supporting cognitive engagement and quality of life.

Limitations

There are several limitations of this study. First, due to the COVID-19 pandemic, we were unfortunately unable to follow up with some participants throughout the process, resulting in their loss from the study. The pandemic also necessitated off-site meetings with transportation provision, which may have excluded some potential participants with mobility limitations or discomfort with van travel. Second, established trust relationships that facilitated recruitment may have introduced response bias, as participants with prior positive experiences with the research team may have been more inclined to provide favorable feedback. Given that real-world implementation will inevitably encounter residents who are skeptical, mistrustful of institutional technology, or uninterested in smart speaker–based applications, purposive recruitment of such individuals would elicit insights that a self-selected, engaged sample cannot provide. Third, incorporating diverse and sometimes contrasting ideas into the design was challenging. While we used multiple data synthesis methods, a more systematic approach to identifying and prioritizing user demands (eg, conjoint analysis or formal prioritization exercises) would have been beneficial for making design trade-off decisions explicit. Fourth, hearing-related concerns, such as hearing loss that hinders meaningful engagement with smart speakers, did not emerge spontaneously in focus group discussions. This absence may reflect sample characteristics or participants' limited awareness of the relationship between hearing ability and voice interface usability. Although smart speaker designs incorporate features such as adjustable volume and visual display companions that may support more equitable access, their adequacy in practice remains unclear. Future work should more explicitly examine how hearing loss shapes engagement with smart speakers. Fifth, while we adapted facilitation approaches to encourage broad participation, differential comfort with technology discussions likely shaped whose voices were most prominent in certain design decisions. Furthermore, differences in age, education, technology access and usage, and prior smart speaker experience among participants may have influenced the outcomes at each phase of the study. Finally, this study focused on early-stage prototyping and scenario development. The scenarios represent

XSL•FO
RenderX

participant aspirations and preferences but have not been validated through implementation.

Conclusions

Our study identified the needs for meaningful connections and safe, independent living among older adults living alone in affordable housing and showed the potential of smart speakers and their voice agents to address social isolation and reduce loneliness. Through a 3-stage iterative UCD process, we successfully engaged residents, including those with limited technology experience, in co-designing 7 prototype scenarios across 4 functional domains. The UCD methods used in this study effectively incorporated end user feedback to develop a technology platform for reducing social isolation and loneliness in this population [42]. Findings emphasize the importance of accessible, thoughtfully designed technology tools for social connectedness and more broadly for health and well-being tailored to older adults with limited resources and digital literacy. Further research is needed to fully develop these prototypes into functional applications, pilot-test them in real-world settings, and evaluate their effectiveness in addressing the unique social health needs of underserved older adults. Future evaluation should also extend beyond self-selected participants to deliberately engage skeptical residents, individuals with institutional mistrust, and those for whom this technology is not an intuitive fit. Rather than assuming universal applicability, research should iteratively test and refine these prototypes across diverse residential contexts, trust environments, and user dispositions to generate a more grounded and transparent evidence base to implementation in affordable housing communities.

Acknowledgments

The authors thank all the participants in the study who made outdoor trips during the pandemic to participate in focus group sessions. The authors express their gratitude to Greg Ford, Director of Program Development and Implementation at Beacon Communities; Normal Dorsett, Senior Community Coordinator at a Winn Residential Managed Community; and Kate Noon, Director of Senior Services at Better Housing Coalition at the time of participant recruitment and data collection. The authors are also grateful to Katherine Falls, Director of Clinical Operations at Mobile Health and Wellness Program at Virginia Commonwealth University. Also, this work is dedicated to the memory of Dr Pamela Parsons, Associate Dean for Practice and Community Engagement at Virginia Commonwealth University School of Nursing, at the time of study design and execution. Without their support, this research would not have been possible. During the preparation of this manuscript, generative artificial intelligence tools were used solely as an editorial assistance tool to improve clarity, conciseness, organization, and grammar of draft responses. The authors have thoroughly reviewed and edited the content and remain fully responsible for the accuracy, originality, and integrity of the final manuscript.

Funding

This work was supported by the National Institutes of Health (R03AG069816 to JC).

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JC conceptualized the project, secured funding, administered and coordinated the project, secured recruitment sites and resources, led data collection and analysis, and led the process of manuscript writing and revision. NM and REW assisted the team in recruiting participants, collecting data, and analyzing data. TG participated in data analysis. GD assisted JC in study conceptualization and data interpretation. All authors participated in manuscript writing, revised the manuscript, and reviewed the final manuscript.

Abstract

Background: Intergenerational communication has been recognized as a key factor in enhancing social connections among older adults by improving the quality of interactions, which is a crucial component of healthy aging. However, effective interventions to foster intergenerational communication and engagement remain scarce at this stage.

Objective: This study examined the effects of a gamification intervention for intergenerational dialogue on intergenerational communication and health-related capacity across 3 age cohorts and further analyzed the differential impacts of intervention characteristics on the game experience, in terms of satisfaction and engagement.

Methods: A 2-stage exploratory method was adopted with a cocreation approach to develop a theoretical framework of intergenerational dialogue for the gamification-based intervention, the Healthy Aging in Dialogue Tabletop Game, followed by a mixed methods study involving pre- and postintervention surveys and qualitative interviews to evaluate the effectiveness of the intervention in the young (aged 18 - 39 years), middle-aged (aged 40 - 64 years), and older adult (aged ≥65 years) groups. Intergenerational communication was assessed using tools measuring satisfaction and competence, whereas health-related capacity was evaluated using health literacy and patient enablement tools.

Results: A total of 68 respondents completed the intervention and evaluation, with 23, 14, and 31 respondents in the young, middle-aged, and older adult groups, respectively. This intergenerational intervention yielded notable benefits in intergenerational communication satisfaction (Cohen *d*=0.745), communication competence (Cohen *d*=0.377), and health literacy (Cohen *d*=0.409), especially among older adults. Patient enablement was significantly higher in older adults (mean score 6.10, SD 2.18) than in young adults (mean score 4.22) (*P*=.04). In addition, this study highlighted the importance of leveraging gamification to enhance intergenerational communication and engagement, ultimately combating social isolation among older adults.

Conclusions: The intergenerational dialogue tabletop game provided an enjoyable platform for cross-generational dialogue and enhanced each age group's communication competence, allowing participants to contribute and learn from one another. The findings provide additional evidence for aging research and shed light on approaches to foster social interaction and connection, thereby promoting health and active aging.

KEYWORDS

intergenerational communication; health; gamification intervention; social isolation; social connection; aging

Introduction

Rapid technological advancement, urbanization, and aging have significantly reshaped social dynamics, family structures, and community engagement, leading to fewer face-to-face interactions. Evidence shows that digital communication increasingly replaces face-to-face interactions [1], with individuals often withdrawing from in-person contact due to technology use and fast-paced lifestyles [2]. These societal shifts, combined with changing family structures linked to population aging, contribute to reduced intergenerational engagement and weakened community ties [3]. Among these

XSL•FO
RenderX

transformations, social isolation has emerged as a critical concern since the 1990 s due to its profound implications across levels of society, including individuals, families, workplaces, disease groups, and broader society [4,5]. Social isolation is defined as the objective absence or insufficiency of meaningful and sustained communication [6], reflected in having too few interactions with others. It has become a priority global health issue recognized by the World Health Organization (WHO) and the United Nations, with an estimated 25% of older people and 15% of adolescents experiencing social isolation [7] because it has been linked to numerous adverse outcomes documented by a growing body of evidence, such as mental health decline, depression, dementia, cardiovascular disease, stroke, falls, reduced quality of life, hindered active aging, and increased mortality rates [8,9]. Our preliminary work shows that prevailing circumstances, such as pandemics, climate change, policies, family crises, and health deterioration, further intensify social isolation [10,11]. Loneliness, by contrast, represents a distressing feeling arising from a perceived and experienced lack of interaction [6]. Although social isolation is an objective form of social disconnection, whereas loneliness is a subjective form, they are strongly related [12], and both forms of disconnection carry significant health risks [7,13].

Many intergenerational programs have been shown to mitigate social isolation and loneliness by strengthening cross-age communication and expanding older adults' social networks [14-16]. Intergenerational communication, defined as the exchange of ideas, values, and experiences between different age groups [17], has been recognized as a key factor in addressing social isolation by fostering mutual understanding and improving the quality of intergenerational interactions within an intergenerational program [15]. Existing intergenerational programs mainly focus on structured connections and individual-based interactions (eg, one-way storytelling, companionship for social and health support), and community-based activities (eg, group-based activities related to arts, gardening, physical activity, cooking, digital games, volunteering, and neighborhood support) [14-16]. The conversation-based program remains limited, despite being the central component of social connection. Without engaging in dialogue topics or accommodating communication practices, social isolation can be perpetuated. Key components of communication include listening, observing verbal and nonverbal cues, and expressing thoughts and emotions through both verbal and nonverbal channels [18], all of which are essential for achieving mutual understanding, building a trusting relationship, and fostering an empathetic and caring environment [19]. When individuals lack adequate communication skills or have limited exposure to diverse conversational partners, they may struggle to accurately interpret others' cues or express themselves effectively. This is particularly evident in intergenerational contexts. Giles and Gasiorek [20] found that younger adults often overaccommodate older individuals through overprotection, whereas older adults tend to underaccommodate younger individuals by voicing harsh criticisms of their generation. A lack of intergenerational understanding may deepen generational divides, leading to age stereotypes that may contribute to nonaccommodation [21]. Without engaging in dialogue topics or practicing accommodating communication strategies, social isolation can be reinforced. Furthermore, most programs are time-limited, and older adults often lose access to the platforms and opportunities that enable ongoing interaction with younger people, leading to a decline in sustained engagement.

Given that the intervention was explicitly designed to structure and enhance intergenerational dialogue, this study focuses on proximal communication outcomes, specifically communication competence and communication satisfaction, as direct indicators of interaction quality. Although social isolation and loneliness motivate this work as broader public health concerns, these outcomes are conceptualized as distal and likely to emerge through sustained improvements in the communication process over time. Accordingly, this study evaluates the effects of the intervention on communication-related outcomes, providing a necessary foundation for future research to examine downstream impacts on social isolation and loneliness. This paper addresses this gap by developing a structured intergenerational tabletop game as a repeatable, low-cost platform that provides guided conversation topics and supports the four key communication components as intervention mechanisms that facilitate meaningful interaction beyond formal programs: guided conversational exchange; shared problem-solving through cooperative tasks; perspective-taking and mutual learning across generations; and opportunities to practice and build confidence in communication competence. Additionally, the intervention embedded health content to enhance health literacy and enablement, supporting participants' capacity to sustain and apply communication gains, as poor health literacy has been recognized by the WHO as a key driver of social isolation and a diminished capacity for social participation [3].

Methods

Overview

A 2-stage exploratory method was used to develop intergenerational dialogue prototypes for the gamification-based intervention and to evaluate its effectiveness on the communication process. Gamification was adopted to incorporate game-based intervention elements such as points, leaderboards, and badges into a nongame context to enhance the engagement experience [22]. This study investigated the effectiveness of the "Healthy Aging in Dialogue Card Game" on intergenerational communication, health, and game experience in three age cohorts: 18 - 39 years, 40 - 64 years, and ≥65 years. The objectives were to evaluate communication skills (communication competence and satisfaction), health literacy, self-efficacy, and engagement in the game (fun, encouragement to communicate, health knowledge building, and satisfaction) across age groups in the pre- and postsurveys.

Study Population

Overview

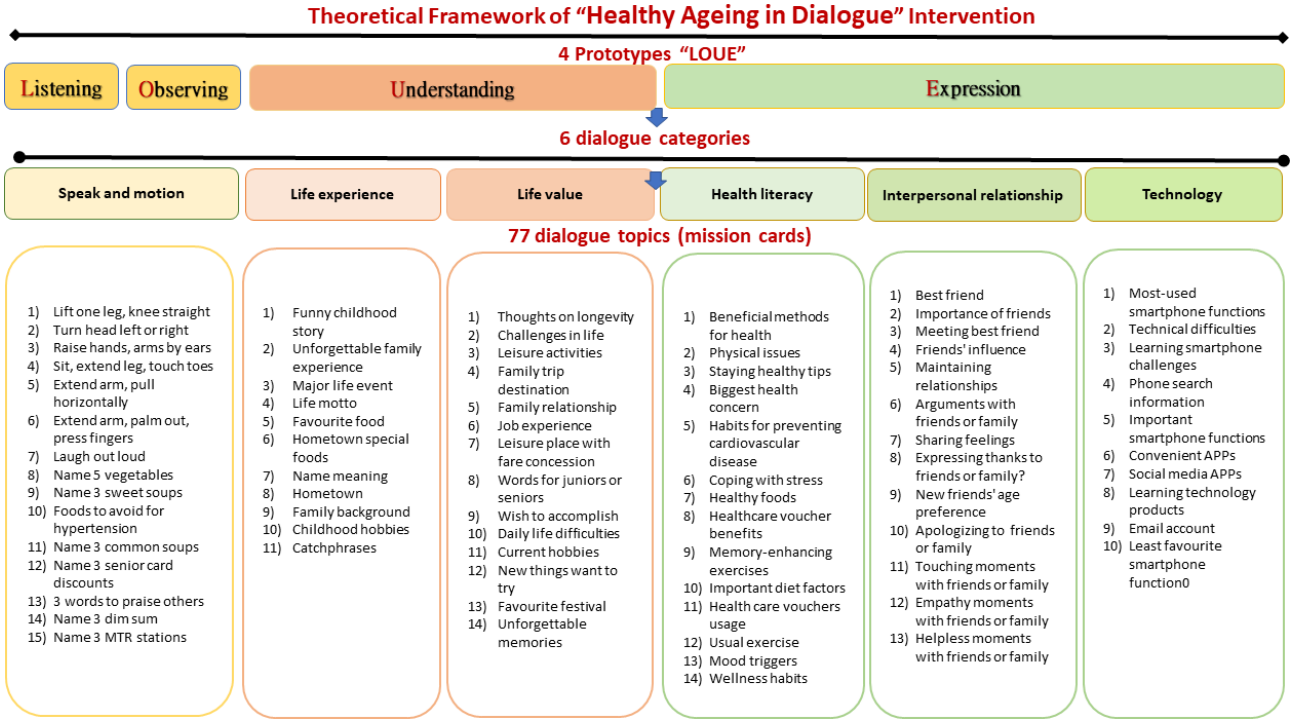
Participants who were Hong Kong residents and spoke Cantonese as their native language were eligible for the study, while those without the cognitive capacity to provide consent were excluded. Recruitment of young adults aged 18 - 39 years and middle-aged adults aged 40 - 64 years was conducted via

XSL•FO
RenderX

mass mailings at universities and social media, including Facebook (Meta Platforms, Inc) and Instagram (Meta Platforms, Inc). Older adults aged 65 years or older were recruited by nongovernmental organizations via flyers and a multicommunity-center approach.

Stage 1: Cocreation and Prototype Development for Intergenerational Dialogue

The development of the intergenerational dialogue intervention followed the revised Medical Research Council guidance for complex interventions [23], with an emphasis on theory-driven design, stakeholder input, and iterative refinement. A 4-member cocreation team, comprising an academic with training in nursing and public health (ELYW), a social worker, a public health practitioner (CKPW), and 1 potential end user (SSKL), led the multistage development process.



Theoretical Framework: Listening, Observing, Understanding, and Expression

The intervention was theoretically informed by the Listening, Observing, Understanding, and Expression (LOUE) framework, which integrates core verbal, nonverbal, and emotional communication processes [18]. LOUE was selected because it aligns closely with the goals of intergenerational dialogue, where effective communication depends not only on verbal exchange but also on emotional attunement, reciprocal self-disclosure, and perspective-taking. Specifically, active listening and empathic engagement are fundamental to building understanding and trust in interpersonal communication [24], while emotional attunement enables individuals to perceive and respond sensitively to others' affective states [25]. Perspective-taking further supports interpersonal connection by allowing individuals to understand others' thoughts and viewpoints, and reciprocal self-disclosure fosters relational closeness and social bonding [26]. In this study, LOUE served as a design framework to guide the generation, classification, and structuring of dialogue prompts, ensuring that gameplay systematically exercises these 4 communication skills.

Identification of Dialogue Categories and Topic Generation

At the identification stage, the cocreation team reviewed evidence from intergenerational communication and health promotion programs [27,28] and collaboratively identified recurring thematic domains relevant to everyday intergenerational interactions. Through iterative discussion and clustering of draft prompts, six dialogue categories, defined as thematic groupings of communication prompts, were agreed upon: (1) Speak and Motion, (2) Life Experience, (3) Life Values, (4) Health Literacy, (5) Interpersonal Relationship, and (6) Digital Literacy (Figure 1). Building on these categories, the team generated an initial pool of conversation prompts and refined them based on relevance, clarity, and suitability for group dialogue. This process resulted in 77 dialogue topics, which were further refined through a design review to ensure balanced representation across categories and suitability for delivery in a game-based format.

Figure 1. Theoretical framework of the Healthy Aging in Dialogue intervention. MTR: metro.

Operationalization as Mission Cards and Intervention Structure

The 77 dialogue topics were operationalized as mission cards, each containing a structured prompt designed to elicit turn-taking dialogue and reflection. Mission cards were evenly distributed across the 6 dialogue categories. Each card primarily targeted 1 LOUE dimension (eg, listening or expression), while still engaging all 4 communication skills through interaction and response. This structure ensured that each game turn focused on a specific topic while cumulatively strengthening intergenerational communication competencies.

XSL•FO
RenderX

Gamified Tabletop Intervention Design

These mission cards were embedded within a gamified tabletop board game titled the "Healthy Aging in Dialogue Tabletop Game." The intervention consists of players taking turns drawing mission cards, completing dialogue tasks, and accumulating points through participation rather than correct performance. Each player selects a chess piece at the start of the game to represent equal participation and balanced turn-taking, highlighting intergenerational communication as a reciprocal process.

Gamification elements were incorporated to enhance engagement, self-expression, and motivation [29]. A point-based system (1‐3 points, reflecting increasing depth of conversational engagement, ranging from factual exchanges to meaning-making and reflective discussion) was used. Evidence suggests that such gamification strategies can promote interaction, maintain autonomy, and sustain engagement [29,30]. Importantly, 58 of 77 (75%) mission cards require the active involvement of multiple players, such as inviting adjacent or all players to respond, thereby encouraging listening, observing others' perspectives, and shared reflection [31-33].

Game Format and Play Procedure

The intervention is designed for 3‐6 players aged 11 years or above, with each group comprising at least 1 young adult (18‐39 years), 1 middle-aged adult (40‐64 years), and 1 older adult (≥65 years). A typical game session lasts 20‐30 minutes, or until a preset endpoint is reached, to maintain attention and prevent conversational dominance. Players take turns clockwise, draw mission cards, and complete tasks within approximately 1‐2 minutes per turn. There are no correct answers, and judgmental feedback is discouraged to maintain a respectful and inclusive dialogue environment. Details of the game setup and rules are provided in Figure 2.

XSL•FO
RenderX

Figure 2. Healthy Aging in Dialogue Tabletop Game.

- This game helps players from different generations talk, listen, and learn from each other. By complementing mission cards and moving across the game board, players explore six areas of everyday life – actions, life experience, value, health, relationships, and technology – while strengthening communication skills and understanding across ages.
- Setup includes three parts: 1 Score Board, 77 Mission Cards, and 6 Chess. Recommend having 3-6 participants from different generational groups.

Game rule

1. Each player chooses one chess piece and places it at the starting point.
2. Shuffle the mission cards and place them facing down on the table.
3. Players' orders are decided by group consensus. For example, the youngest player starts, or the player with the latest birth month starts.
4. The first player flips over the top card from the shuffled deck, then answers the question or performs the task shown on the card. There are no right or wrong answers, only moments to connect, share, and enjoy others' company.
5. The card may invite different players to participate:

   i. All players participate.
   ii. You and the player on your left participate.
   iii. You and the player on your right participate.
   iv. You and the players on both your left and right participate.
   v. Only you participate.
6. After fulfilling the required task, the player(s) gain points and move their chess forward with the number of steps (ranging from 1 to 3) indicated on the mission card.
7. Players take turns in a clockwise manner by revealing the next top mission card.
8. Recommended play time is about 30 minutes; the first player to reach the end or the player with the highest score within the time limit wins the game.

Stage 2: Mixed Methods Evaluation of the Effectiveness of the Gamification-Based Intervention

A mixed methods study method consisting of a 2-phase longitudinal survey and follow-up qualitative sessions involving focus group or individual interviews was conducted on-site to evaluate the effectiveness of the gamification-based intervention—the Healthy Aging in Dialogue Tabletop Game. Before the intervention, all participants completed the baseline questionnaires independently or with assistance from a trained

XSL•FO
RenderX

research assistant. Immediately after the intervention, they completed the follow-up questionnaire. A minimum sample size of 63 was recommended to detect a medium effect size of 0.5 at a significance level of .05 and statistical power of 80%, with the assumed SD of 1 [34]. The questionnaire consisted of the following four sections: (1) intergenerational communication, (2) health-related capacity, (3) game experience (postintervention only), and (4) demographics (baseline only).

Primary Outcome Measure

Intergenerational communication was assessed in terms of communication satisfaction and communication competence. Communication satisfaction was assessed using four conceptually relevant items selected from Hecht Interpersonal Communication Satisfaction Inventory [35]. The item "I felt I could talk about topic with the other person" was modified from "anything" to "topic" to fit the structured dialogue context, while the remaining three items—"I am generally satisfied with the conversations," "I enjoy the conversations," and "These conversations flow smoothly"—were directly adopted. All items were rated on a 6-point Likert scale ranging from "1=extremely disagree" to "6=extremely agree." Communication competence was evaluated using 6 selected items from the Interpersonal Communication Competence Scale (ICCS) [36], reflecting perspective-taking, emotional awareness, conversational flow, topic management, and sensitivity to nonverbal cues: (1) I can put myself in others' shoes, (2) I do not know exactly what others are feeling, (3) other people think that I understand them, (4) my conversations are characterized by smooth shifts from one topic to the next, (5) I take charge of conversations I am in by negotiating what topics we talk about, and (6) in conversations, I perceive not only what others say but also what they do not say. Responses were rated on a 4-point Likert scale ranging from "1=extremely disagree" to "4=extremely agree."

Secondary Outcome Measures

Health-Related Capacity

Health-related capacity was evaluated using measures of health literacy and enablement. Health literacy was assessed with three items from the European Health Literacy Survey Questionnaire (HLS-EU-Q47) [37], including (1) finding information on treatments of illness that concern you, (2) finding information on how to manage mental health problems such as stress or depression, and (3) judging which everyday behavior (such as drinking and eating habits and exercise) is related to your health. Responses were rated on a 4-point Likert-scale ranging from "1=very difficult" to "4=very easy." A Chinese version of the HLS-EU-Q47 was previously validated to assess health literacy in Chinese populations [38]. Self-care competence was examined by adapting 6 items from the Patient Enablement Instrument (PEI) to the intervention context: (1) able to cope with life, (2) able to understand your health condition, (3) able to cope with your health condition, (4) able to keep yourself healthy, (5) confident about your health, and (6) able to help yourself. Responses were rated on a 3-point Likert scale: "much better," "better," and "same or less." The original PEI was previously translated and validated in the Chinese population [39].

Game Experience

Game experience was evaluated after the intervention using the following five questions about the board game: (1) fun to play, (2) encourage intergenerational communication, (3) enhancement of health knowledge, (4) satisfaction with the mission card design, and (5) overall satisfaction with the experience. Responses were rated on a 4-point Likert scale ranging from "extremely disagree" to "extremely agree." Participants were also asked about their perceived game engagement on a 10-point scale ranging from very disengaged (0) to very engaged (10).

Demographic data were collected before the intervention, including age, gender, living arrangement, education attained, marital status, religion, and self-reported noncommunicable diseases.

All participants were invited to focus group discussions immediately after the game intervention and post survey to collect immediate narrative feedback. The focus groups, consisting primarily of participants from the same age group, were conducted to explore the dialogue experience and views on the board game design. For participants who could not join the focus groups but wished to elaborate on their opinions of the board game, in-depth individual interviews were scheduled within 10 days of their board game experience to minimize recall bias. The focus group discussions and individual interviews lasted approximately 45 - 60 minutes, were audiotaped, and participants were invited to freely express relevant ideas on the discussion topics. The qualitative interviews were led by researchers experienced in qualitative data collection using a discussion guide to discuss [40] with three major components, including (1) attitudes toward intergenerational communication, (2) healthy aging, and (3) views on the design and application of the card game.

Data Analysis

A quantitative analysis of the survey responses was conducted using IBM SPSS (version 29.0). Sample characteristics were reported as descriptive statistics. Items related to intergenerational communication satisfaction, communication competence, health literacy, and the patient enablement index were summed to yield total scores, whereas paired *t* tests were performed to detect significant changes in target outcomes with 95% CIs. Subgroup analyses by age group were further conducted to examine the impact of the card game across different generations. Cohen *d* of the three target outcomes (intergenerational communication satisfaction, communication competence, and health literacy) was computed using the mean difference before and after the intervention to evaluate the effect sizes, and Hedges correction was applied for subgroups with n<20 [41]. Effect sizes were considered small, medium, and large with cutoffs of 0.2, 0.5, and 0.8, respectively [41,42]. Findings related to key game experience components, including "fun to play," "encourage intergenerational communication," "enhance health knowledge," and "satisfied with board game question and mission design," were first presented descriptively. To further examine the associations between the key game experience components and the likelihood of reporting higher levels of overall satisfaction and game engagement, multivariate

XSL•FO
RenderX

binary logistic regression models were conducted. For these analyses, the original Likert-scale or continuous scale outcome variables were dichotomized into "higher" vs "lower" satisfaction or engagement. A higher level of satisfaction was defined as a response of "strongly agree" on the 4-point Likert satisfaction scale, while a higher level of engagement was defined as a score of 9 - 10 on the 0 - 10 engagement scale. The reported odds ratios (ORs) and corresponding 95% CIs were adjusted for age group in the models. A *P* value of <.05 was considered statistically significant.

Audiotapes recorded during the qualitative sessions were transcribed verbatim, and the transcripts were managed with Microsoft Excel. Experiences related to the game in three aspects, including intergenerational communication, health-related capacity, and overall playing experience, were identified by thematic analysis. The themes and quotes were identified with reference to the discussion guide, and the transcripts were coded twice by 2 independent reviewers to develop the study codebook. With the emergent and recurrent themes identified from the transcripts, these codes were checked and discussed among the independent reviewers to enhance consistency throughout the analysis. Codes were discussed among the research team in case of disagreements. Excerpts were quoted to illustrate the findings uncovered from the qualitative phase.

Ethical Considerations

The tabletop game intervention is a component of a social isolation project approved by the Chinese University of Hong Kong Survey and Behavioral Research Ethics Committee (SBRE-21 - 0870). Before the game intervention, informed consent was obtained from participants for participation in the game, surveys, qualitative interviews, and audiotaping.

Results

Demographics

A total of 81 participants were enrolled in the tabletop game, and 68 completed the intervention and evaluations, yielding a response rate of 84%. A total of 19 game groups were arranged, each involving 3 - 5 participants with at least 1 participant from each of 3 age groups. Participants were distributed across the 3 age groups (Table 1). The majority of participants were female (82.4%), living with others (61.8%), had a tertiary education level or above (55.4%), were single (47.1%), and had no religious belief (52.9%). About half of the participants reported having a communicable disease (48.5%). After the intervention and post survey, 52 of 68 (76.5%) participants were interviewed in 8 focus groups and 3 individual interviews. Only 1 focus group was mixed-aged, and 3 individual interviews were arranged due to the unavailability to join the focus group. There was no difference in the direction or richness of sharing; therefore, all focus groups and individual interviews were combined for data analysis. Regarding the characteristics of the interviewees across the 3 age groups, a higher proportion with tertiary education, who were single, who had no religious belief, and who had no chronic disease was observed among the youth, while a higher proportion living alone and being widowed or divorced was observed in the middle-aged and older adult groups. The majority of participants were female (80.8%) across all 3 age groups.

Table . Demographic characteristics of respondents.

Demographic	Total (n=68), n (%)	Young (n=23), n (%)	Middle-aged (n=14), n (%)	Older adults (n=31), n (%)
Age range (years)	19 - 92	19 - 33	46 - 64	66 - 92
Sex				
Male	12 (17.6)	7 (30.4)	1 (7.1)	4 (12.9)
Female	56 (82.4)	16 (69.6)	13 (92.9)	27 (87.1)
Live status				
Living alone	26 (38.2)	1 (4.4)	4 (28.6)	21 (67.7)
Living with others	42 (61.8)	22 (95.6)	10 (71.4)	10 (32.3)
Education level				
Primary or below	7 (10.3)	0 (0.0)	0 (0.0)	7 (23.3)
Secondary	23 (33.8)	1 (4.3)	5 (35.7)	17 (56.7)
Tertiary or above	37 (54.4)	22 (95.7)	9 (64.3)	6 (20.0)
Relationship status				
Single	32 (47.1)	19 (82.6)	3 (21.4)	10 (32.3)
Married or stable relationship	18 (26.5)	3 (13.0)	7 (50.0)	8 (25.8)
Widowed or divorced	18 (26.5)	1 (4.3)	4 (28.6)	13 (41.9)
Religion				
No	36 (52.9)	17 (73.9)	3 (21.4)	16 (51.6)
Yes or traditional worship	32 (47.1)	6 (26.1)	11 (78.6)	15 (48.4)
Self-reported noncommunicable disease				
No	35 (51.5)	21 (91.3)	8 (57.1)	6 (19.4)
Yes	33 (48.5)	2 (8.7)	6 (42.9)	25 (81.6)

Intergenerational Communication

There was a significant improvement in the participants' self-ratings of communication satisfaction, with a mean difference of −2.76 (95% CI −3.66 to −1.87; Table 2). Participants across all 3 age groups showed significant improvement after the intervention, with mean differences of −2.52 in young adults, −3.93 in middle-aged adults, and −2.42 in older adults. The largest effect size was observed in the middle-aged group (Cohen *d*=1.13). For participants' ratings of communication competence, significant improvement was also observed after the intervention, with a mean difference of −1.04 (95% CI −1.71 to −0.37). Improvement was shown across all 3 age groups, but statistically significant improvement was observed only among older adults, with a mean difference of −1.32 (95% CI −2.52 to 0.12). Comparing the 2 communication dimensions, a larger effect size was observed for communication satisfaction (medium effect size of 0.75) than in communication competence (small effect size of 0.38) after the intervention.

Competence				
Intervention, mean (SD)	18.66 (2.33)	19.34 (2.21)	18.79 (2.36)	18.10 (2.34)
Baseline intervention, mean (95% CI)[a]	−1.04 (−1.71 to −0.37)[c]	−1.09 (−2.23 to 0.06)	−0.36 (−1.22 to 0.51)	−1.32 (−2.52 to −0.12)[c]
Cohen *d*[a]	0.377	0.411	0.224	0.404

[a]Cohen *d* was computed with the mean difference by Hedges correction for n<20.

[b]Paired *t* test.

[c]*P*<.05

Qualitative interviews supported these quantitative findings, showing that the intervention facilitated easier and more relaxed communication.

A young participant remarked:

> *Sometimes, when talking to middle-aged and older individuals, you may not always know what to say. Not everyone is skilled in discussing various topics with others. On the contrary, this approach raises topics for conversation on which everyone can share their opinions. It's not too tense, and it makes the conversation with them much easier.* [BG22 (E)]

A middle-aged participant further added:

> *… as players often raise different answers, the contrast between them may stimulate even the shy ones to stay engaged with the tasks and responses. This promotes communication, or even builds the trust for any physical assistance with the action tasks when necessary.* [CUBG35 (B)]

An older adult participant also shared:

> *The gamification provides a welcoming space to share personal matters (anonymously), which helps players to soothe and relax, especially on sensitive topics that might be difficult to bring up with friends, as you may be uncertain if the friend may spread the word unintentionally.* [BG26]

Health-Related Capacity

Health literacy significantly improved after the intervention (Table 3). Across the 3 age groups, significant improvements in health literacy with a significant result were observed in the middle-aged (mean difference −0.86, 95% CI −1.60 to −0.11) and older adult groups (mean difference −1.19, 95% CI −1.96 to −0.43) but not in the youth group (mean difference −0.13, 95% CI −0.88 to 0.62). Focusing on the patient enablement effect of the tabletop game intervention, PEI scores significantly increased (Table 3). A comparison of results across the 3 age groups showed that older adults' PEI (mean 6.10, SD 2.18) was significantly higher than that of the young adult group (mean 4.22, SD 2.59). However, no significant difference was observed in the other comparisons. Details of the comparisons are tabulated in Table 2.

[e]PEI: Patient Enablement Instrument.

[f]For the post hoc test (Bonferroni): 1=young, 2=middle aged, and 3=older adults.

Qualitative data corroborated these results, and a young participant indicated the benefits of the intervention in enhancing health literacy, particularly regarding mental health:

> *There were several cards that addressed topics like how to cope when you're under a lot of stress, or what might make you feel down emotionally. When discussing these topics, everyone can reflect more on their own experiences. It makes us think about times when we ourselves may have felt a lot of emotional pressure or faced emotional issues. Some of the cards also ask how you would cope with such situations, and everyone can share their experiences. This allows for the exchange of skills and strategies for dealing with various topics.* [BG22 (E)]

A middle-aged participant highlighted:

> *The youth and I (middle-aged) had no idea of the welfare offered by the healthcare voucher or the senior citizen card; we had to check online immediately to learn the benefits… it is like acquiring new knowledge. It is not that we don't care, but what we knew was limited, and only then did we realise there are things experienced by the older adults that we lack understanding.* [BG20 (5)]

An older adult participant shared the impact of health literacy:

> *… when you live to a hundred, you would need the help from a carer (social support), and you can't take good care of yourself. This feels powerless, and the other player agrees, sharing the same concern (about Health-related Quality of Life in ageing). We are worried that we become incapable of self-care, and this is not the ideal way (of community ageing).* [BG26]

In terms of patient enablement, a young participant noted:

> *The discussion on the HA Go (mobile application of the Hospital Authority) is important, as it provides information for carers like me, who monitored the health conditions of my family with the HA Go… it is still a means for us to manage health regardless of physical distance...* [CUBG13 (M)]

A middle-aged participant also mentioned:

> *The tabletop game may empower the participants to cope with their future, such as guiding them to think and plan ahead… the positive planning should be for everyone, and everyone should foster a positive mindset.* [BG18 (4)]

An older adult participant expressed:

> *Expressing my thoughts with the game play made me feel more at ease… and by drawing the tasks randomly, we may not dodge from the problem, but to face it directly. It feels like a therapy session, and it's therapeutic.* [BG15 (1)]

Game Experience

A strong positive experience with the tabletop game was revealed, with responses heavily inclined toward "agree" and "extremely agree" in all 4 aspects of game experience. The

XSL•FO
RenderX

highest proportion of participants found that the tabletop game could encourage intergenerational communication, with 51.5% strongly agreeing, followed by "fun to play" (44.1%), "satisfied with mission card design" (30.9%), and "enhanced our health knowledge" (26.5%). The 4 aspects of game experience are reported in Table 4. The association between game experience and engagement, and overall satisfaction is reported in Table 5. It was found that "encourage intergenerational communication" (OR 4.49, 95% CI 1.09 to 18.58) was significantly associated with participants' engagement in the tabletop game, whereas "encourage intergenerational communication" (OR 6.22, 95% CI 1.03 to 37.37) and "satisfied with mission card design" (OR 10.20, 95% CI 1.46 to 71.37) were significantly associated with the overall satisfaction of the tabletop game.

Table . Experience of the gamification-based intervention.

Gamification-based intervention component	Higher level of satisfaction, n (%)	Higher level of satisfaction[a], n (%)	*P* value[b]	Higher level of engagement[c], n (%)	*P* value[b]
Fun to play					
Agree and disagree	38 (55.9)	5 (13.2)	<.001	18 (47.4)	.001
Strongly agree	30 (44.1)	23 (46.7)	<.001	26 (86.7)	.001
Encourage intergenerational communication					
Agree and disagree	33 (48.5)	4 (12.1)	<.001	14 (42.4)	<.001
Strongly agree	35 (51.5)	24 (68.6)	<.001	30 (85.7)	<.001
Enhance health knowledge					
Agree and disagree	50 (73.5)	13 (26)	<.001	28 (56)	.020
Strongly agree	18 (26.5)	15 (83.3)	<.001	16 (88.9)	.026
Satisfaction with board game questions and mission design					
Agree and disagree	47 (69.1)	9 (19.2)	<.001	26 (55.3)	.026
Strongly agree	21 (30.9)	19 (90.5)	<.001	18 (64.7)	<.05

[a]A higher level of satisfaction is defined as "strongly agree" satisfaction.

[b]Chi-square and Fisher exact test were conducted.

[c]A higher level of engagement is defined as scoring 9 - 10 on the engagement question.

RenderX

Table . Relationship between gamification-based intervention components and board game experience.

Board game experience	Higher level of satisfaction[a], adjusted OR[b] (95% CI)	Higher level of game engagement[c], adjusted OR[b] (95% CI)
Intercept	0.07 (0.012 - 0.39)[d]	0.57 (0.19-1.75)
Fun to play		
Agree and disagree	Ref[e]	Ref
Strongly agree	4.63 (0.71 - 30.02)	2.73 (0.48-15.56)
Encourage intergenerational communication		
Agree and disagree	Ref	Ref
Strongly agree	6.22 (1.03 - 37.37)[d]	4.49 (1.09-18.58)[d]
Enhance health knowledge		
Agree and disagree	Ref	Ref
Strongly agree	3.67 (0.24 - 56.60)	1.47 (0.18-12.11)
Satisfied with mission card design		
Agree and disagree	Ref	Ref
Strongly agree	10.20 (1.46 - 71.37)[d]	1.07 (0.16-7.12)

[a]A higher level of satisfaction is defined as “strongly agree” satisfaction.

[b]Adjusted by 3 age groups: 18 - 39 years, 40 - 64 years, and >65 years.

[c]A higher level of engagement is defined as scoring 9 - 10 on the engagement question.

[d]$P<.05$.

[e]Ref: reference group.

Regarding the qualitative findings, participants emphasized the opportunities this game offered for intergenerational interaction. For example, one young participant mentioned:

> *The tabletop game provides a chance, or a platform, for each generation to interact and communicate. You know how busy the locals are, not to mention having meals together, but it was rare for different generations just to sit together. The card game would offer motivation for different generations to come together.* [BG27]

An older adult participant further added:

> *The card game encourages activities between the youth, middle-aged, and older adults. With these opportunities, we may interact and get to know each other in a friendly setting. It is nice that we can engage with real friends.* [CUBG30]

In addition, a young participant expressed enjoyment of the game:

> *I find the game enjoyable. The tasks are simple and easy to complete. As other students shared, there are tasks that are relatively exciting and playful, especially those with a time limit or an action-based format. These game play strategies are challenging yet fun...* [BG25 (C)]

A middle-aged participant also commented on the game’s enjoyable nature:

> *… the older adults seem to enjoy the action tasks, and it’s such a pleasant scene when everyone engages with the same actions on an intergenerational level.* [CUBG34 (H)]

An older adult participant reflected on the intergenerational engagement:

> *I think the card game experience is nice, and it’s my first attendance at such a game. The intergenerational engagement seems to be drawing everyone closer, and I feel involved as it includes topics related to my childhood.* [CUBG29]

The game’s design was recognized as a key factor in its success. A young participant mentioned:

> *I would say, first of all, what impressed me the most was that the rules of the game were very simple… I think the key is to make sure they understand the rules of the game so they are willing to engage. If the rules were too complicated, they would likely spend too much time figuring out what to do and what each element meant. So, I believe ensuring a smooth game operation is crucial for the success of the game experience.* [BG24 (D)]

A middle-aged participant also expressed satisfaction with the game design:

> *It’s obvious that the card game encourages expansion of social network by providing common topics and activities… By involving adjacent players, this is a great design as there will be no dominating players, but they will share the experience together.* [BG20]

An older adult participant also acknowledged the game design:

XSL•FO
RenderX

Introducing oneself through playing cards makes it more interesting for everyone listening. By using this relaxed atmosphere, it allows everyone to get to know each other better. [CUBG25]

Discussion

Principal Findings

This intergenerational intervention yielded notable benefits in intergenerational communication, health literacy, and patient empowerment, especially for older adults. While the majority of gamification interventions for older adults have focused on evaluating the impact on health outcomes [43], the current evaluation provides a comprehensive review of communication and health-related outcomes. In addition, this study highlighted the importance of leveraging gamification to enhance intergenerational communication and ultimately combat social isolation among older adults.

Across all age groups, participants reported significantly higher communication satisfaction post intervention, indicating that the game fostered enjoyable and fulfilling dialogue. While short-term increases in communication satisfaction following an engaging activity are, to some extent, expected and may partly reflect novelty or positive study participation effects, communication satisfaction reflects perceived interaction quality rather than transient mood alone. In this intervention, satisfaction was fostered through structured dialogue, guided turn-taking, and role rotation, which targeted communication processes that can plausibly generalize beyond the immediate gameplay context. Nevertheless, sustained effects cannot be inferred from the present design and require confirmation through longitudinal follow-up. Notably, only older adults showed a significant improvement in their communication competence scores, whereas younger and middle-aged adults did not. One explanation lies in baseline differences: older participants may have had fewer opportunities for rich social interaction before the study due to the prevalence of social isolation among Hong Kong's older population. Indeed, as of 2021, nearly 190,000 adults aged 65 years and older were living alone in Hong Kong, reflecting a 60% increase since 2011 [44]. Such isolation is linked to declines in communication skills and cognitive function [45]. By facilitating regular, meaningful conversations, the game likely helped older participants practice and regain communication competencies. This aligns with evidence that increasing social interaction can improve older adults' performance on verbal communication tasks [46]. In contrast, younger adults—who typically have more daily social communication—may have been closer to a ceiling in communication ability, limiting observable gains.

Differential effects on health literacy were also observed. Middle-aged and older participants showed significant improvements in health literacy after gameplay, whereas the youth group did not. Younger adults likely entered the study with higher baseline health literacy, given their greater exposure to education and digital information, and thus had less room for measurable improvement. Older adults, on the other hand, often start with lower health literacy and greater health knowledge gaps. The game's health literacy module provided an engaging, accessible means of learning health information, resulting in tangible knowledge gains for these groups. This finding is consistent with prior research showing that game-based interventions can substantially increase health-related knowledge [47]. Moreover, intergenerational learning theory suggests that structured dialogue between generations creates opportunities for mutual education and attitude change [48]. During the health literacy tasks, younger players might have shared digital health information or taught health concepts, benefiting their older counterparts. Reciprocally, older adults may have shared personal health experiences, which could enrich understanding for young and middle-aged adults. The middle-aged group, interestingly, also improved in health literacy, suggesting that those in midlife, often caring for both children and older adult parents, found the health knowledge and cross-generational communication practice directly relevant and empowering for their caregiving and self-care roles.

Importantly, the older group showed a significantly higher PEI score post intervention than the youth group, with no significant differences between the other groups. The high PEI score in older adults suggests that the game may have enhanced their confidence and sense of "enablement" in dealing with health issues. Several mechanisms could explain this. First, older participants likely felt a sense of accomplishment and agency by contributing actively to group tasks, such as sharing life experiences or completing challenges. Being listened to by younger peers may have bolstered their self-esteem and sense of purpose, which, according to Socioemotional Selectivity Theory, is highly valued in late life [49]. The theory posits that as people age and perceive a shorter future time horizon, they prioritize meaningful social interactions and emotional fulfillment. Importantly, this does not imply that brief interactions with unfamiliar partners function as strong-tie relationships; rather, the intervention may have uncovered interaction contexts characterized by emotional affirmation, mutual respect, and psychological safety, which align with the socioemotional qualities prioritized in later life. In our study, the older adults' disproportionate gains in communication ability and health literacy could be a good start toward confidence-building in intergenerational interaction and a strong sense of enablement. Moreover, the opportunity to impart wisdom and bond with younger people likely fulfilled older adults' socioemotional goals, thereby maximizing their engagement and leading to greater gains from the program. In contrast, younger participants generally have a more future-oriented outlook and myriad social connections; while they enjoyed the game, as evidenced by improved satisfaction, they may not have experienced the same degree of program gains or personal empowerment.

The outcome was a unanimous perception across all age groups that the game strengthened intergenerational communication and was well-designed, fun, and educational. These positive subjective evaluations are noteworthy given the challenge of designing content appealing to diverse ages. By using gamification—points, challenges, and playful interactions—the intervention kept participants intrinsically motivated. Gamification theory holds that introducing game elements into nongame contexts (such as health education) can enhance user

XSL•FO
RenderX

engagement and motivation [50]. Consistently, our findings show high engagement and satisfaction scores, indicating that the game format was indeed engaging. Prior studies in older adults have also found that appropriately designed card games can acutely boost mood and well-being during play [51]. Our intergenerational game seems to have capitalized on these effects, creating an enjoyable learning environment that felt less like a health workshop and more like a social gathering.

The association analyses provide further insight into what drove the intervention's success. We found that participants who felt the game "encouraged intergenerational communication" were significantly more likely to report higher engagement in the activities and greater overall satisfaction, reinforcing the importance of perceived interaction quality as a proximal outcome. In other words, when players perceived that the core purpose of the game, bridging generations, was being achieved, their involvement and satisfaction were maximized. This underscores the importance of making the intergenerational benefits salient—participants who recognized the value in connecting with other ages likely invested more effort and attention, potentially creating a virtuous cycle of engagement and positive experience. We also found that satisfaction with the game design was strongly correlated with overall satisfaction. This highlights the role of user-centered design, encompassing elements such as clear rules, culturally relevant content, and balanced difficulty across modules, which likely enhanced enjoyment. From a gamification perspective, well-designed game mechanics (eg, rotating tasks, creative challenges, and immediate feedback through group discussion) can fulfill psychological needs such as autonomy, competence, and relatedness, leading to higher satisfaction [52].

Limitations

First, although the inclusion criteria were broad, participants voluntarily enrolled in the intervention, and the majority were female, which may not be representative of all eligible individuals; selection bias may therefore limit generalizability. However, the qualitative interviews provided in-depth insights that may help inform the design of a larger-scale randomized controlled trial. Second, intergenerational communication outcomes were assessed using selected items from validated instruments rather than the complete scales. While this may limit psychometric completeness, the selected items were purposefully chosen to reflect communicative processes relevant to brief, structured intergenerational interactions within a gamified setting. Accordingly, findings should be interpreted with appropriate caution. Full-length scales include items less applicable to this context, and their use may compromise relevance and participant engagement. Third, some outcomes were dichotomized for analysis due to skewed response distributions, which may have reduced variability and statistical power and potentially obscured differences in participants' responses. Fourth, the sample size for the middle-aged group was comparatively smaller than that of the other 2 groups, although the minimum sample size requirement was met. This imbalance may have limited statistical power for 3-group comparisons. Finally, a 30-minute game duration was recommended, but this was not implemented strictly to sustain positive game dynamics. Variations in actual game time may influence comparisons across groups. However, these variations may also reflect natural engagement patterns in intergenerational communication settings.

In conclusion, the intergenerational card game intervention in Hong Kong demonstrated an effective approach to enhancing communication satisfaction, health literacy, and health enablement, particularly benefiting older adults in an aging, isolated population. By providing an enjoyable and structured platform for cross-generational dialogue, the game enabled meaningful engagement and mutual learning between age groups, fostering high levels of participant engagement. These findings underscore the potential of playful, socially embedded interventions to complement traditional health care services by addressing psychosocial determinants of health. Given its low cost, scalability, and high acceptability, this approach holds promise as a public health tool in aging societies worldwide. Future research should further examine the tool's psychometric properties and extend this work through randomized controlled trials or longitudinal studies to assess longer-term impacts on health behaviors, clinical outcomes, and broader dimensions of social connectedness.

Acknowledgments

The authors are grateful to the Tung Wah Group of Hospitals for their joint efforts in cocreating the card game, recruiting older adults, and arranging the intervention's logistics. Tad Chun-kwan Ho was a major contributor to the card game development as a social worker, while Leopard Chi-keung Lam and Danielle Man-yu Chan provided tremendous support in the tabletop game development. Last but not least, the authors thank all participants for joining the game and sharing their valuable views. No generative artificial intelligence tool was used.

Funding

We thank the Hong Kong Jockey Club Charities Trust for its funding support, which made this intervention possible.

Data Availability

The dataset used or analyzed is not publicly available due to confidentiality considerations and the ongoing project progress. A reasonable request may be made to the corresponding author for further consideration.

Authors' Contributions

Conceptualization and funding acquisition were undertaken by ELYW. Data curation was performed by CCWN, CKPW, and SSKL. Formal analysis was conducted by DYW, CCWN, and AWLC. An investigation was carried out by ELYW, CCWN, and DYW. Methodology, supervision, and validation were the responsibility of ELYW. Visualization was completed by CCWN and AWLC. The original draft of the paper was prepared by ELYW, CCWN, and DYW. Review and editing of the paper were undertaken by CKPW, SSKL, AWLC, and EKY.

Conflicts of Interest

None declared.

Abstract

Background: The World Health Organization framework for healthy aging emphasizes that the capacity to establish and sustain relationships is a vital component of functional ability. Social robots offer valuable support for this relational aspect, although their effectiveness is contingent upon the quality of the interactions. While it is established that facial expressions and inclusive behaviors can influence rapport building, the combined effects of these elements on older adults remain unexamined.

Objective: This study aimed to investigate the main and interaction effects of robot facial expression (happy vs unhappy) and interaction style (inclusive vs exclusive) on the development of rapport between social robots and older adults residing in the community.

Methods: A 2 × 2 mixed-factorial experimental design was used in this study, involving 53 community-dwelling older adults (mean age 70.57, SD 4.27 years; n=45, 84.9% female). Participants engaged in a gamified interaction known as Radish Squat featuring 2 humanoid robots that exhibited various combinations of facial expressions and interaction styles. The inclusive robot designated participants within the game 75% of the time, whereas the exclusive robot did so approximately 25% of the time. Dependent measures included robot acceptance, rapport, rapport expectation, and trust. Behavioral designation frequencies were recorded throughout the gameplay. A mixed-design repeated-measure ANOVA was conducted to examine both main and interaction effects.

Results: Facial expression exhibited significant main effects on acceptance ($F_{1,51}$=14.27; P<.001; η^2=0.22), rapport ($F_{1,51}$=6.69; P=.01; η^2=0.12), conversation partner expectations ($F_{1,51}$=11.34; P=.001; η^2=0.18), togetherness expectations ($F_{1,51}$=10.28; P=.002; η^2=0.17), and trust ($F_{1,51}$=4.36; P=.04; η^2=0.08). Interaction style significantly affected rapport ($F_{1,51}$=6.22; P=.02; η^2=0.11), as well as both rapport expectation subscales. Significant interaction effects were also observed for rapport ($F_{1,51}$=8.44; P=.005; η^2=0.14) and trust ($F_{1,51}$=16.62; P=.002; η^2=0.25) such that the positive effect of happy facial expressions was substantially larger under exclusive interaction conditions. Older adults designated the exclusive robot within the game more frequently than the inclusive robot (mean 6.42, SD 1.84 vs 5.32, SD 2.12; t_{52}=2.18; P=.03), and qualitative data pointed to the use of fairness-based turn-taking strategies.

Conclusions: Positive facial expressions and inclusive interaction behaviors significantly enhanced rapport and trust, with synergistic interaction effects primarily emerging under exclusive interaction conditions. The observed patterns, whereby older adults compensated for exclusive robot behavior, suggest that they perceive robots as social entities deserving of equitable treatment. Collectively, these findings offer evidence-based guidelines for designing social robots that foster the relational dimensions of healthy aging.

Introduction

Background

The aging global population necessitates a fundamental shift in our approach to supporting the well-being of older adults. By 2030, it is projected that 1 in 6 individuals worldwide will be aged 60 years or older, and this number is projected to reach 2.1 billion by 2050. In most high-income nations, the age of 65 years is widely accepted as the conventional threshold for retirement and is commonly adopted as a criterion for defining the older adult demographic [1-3]. Accordingly, the World Health Organization has defined healthy aging not simply as the absence of disease but as "the process of developing and maintaining the functional ability that enables well-being in older age" [4-6]. This functional ability, comprising what individuals value in terms of being and doing, emerges from the dynamic interplay between their intrinsic capacity and environmental factors [4,5]. Of the 5 essential domains of functional ability, the capacity to build and maintain relationships is particularly important as social connections profoundly impact stress regulation, cognitive function, and overall well-being [1,6]. However, aging often precipitates social network contraction due to factors such as spousal loss, family dispersion, and mobility limitations. Notably, social isolation has been identified as a mortality risk comparable to smoking [7]. This relational deficit underscores the urgent need for environmental interventions that offer accessible and consistent opportunities for positive social interaction.

Social robots represent a promising environmental resource for addressing this relational dimension of healthy aging. Meta-analytic evidence demonstrates that robot interventions can effectively reduce loneliness and improve psychological well-being among older adults [8,9]. However, the successful integration of social robots into older adults' lives depends critically on interaction quality rather than mere functional utility [10,11]. The computers are social actors (CASA) paradigm establishes that humans unconsciously apply social rules to technological agents, expecting adherence to norms of politeness, turn taking, and emotional congruence [12,13]. For older adults with deeply established social schemas, these expectations are particularly pronounced [11,14]. When robots fail to meet social expectations, the resulting dissonance undermines potential benefits. Therefore, social robots must be conceptualized not as passive tools but as active environmental components whose design features determine whether they enable or hinder the relational aspects of functional ability [14,15].

Rapport, a harmonious relationship characterized by mutual attentiveness, positivity, and coordination [16], emerges as the critical mechanism linking robot design to healthy aging outcomes. When rapport is established, older adults experience enhanced engagement, increased motivation for continued interaction, and greater trust in robot capabilities [17,18]. Research has identified nonverbal cues as primary drivers of rapport formation, with facial expressions serving as powerful signals of social intent [19,20]. Additionally, social inclusion behaviors constitute a fundamental dimension: studies adapting the Cyberball paradigm demonstrate that humans respond to robot-mediated inclusion and exclusion similarly to human interactions [21,22]. However, a critical gap remains. While recent research with university students revealed complex patterns when facial expressions and interaction styles were manipulated simultaneously [23], it remains uncertain how older adults process these potentially conflicting cues. An incongruent robot, one that displays positive expressions while behaving in an exclusive manner, may generate mistrust rather than rapport. Given the distinct generational experiences and varying intrinsic capabilities of older adults [24], understanding the combined effects of these rapport-related characteristics is essential for designing robots that genuinely support healthy aging.

Study Objectives

Driven by the previously mentioned challenges, this study examined the impact of robot facial expressions (happy vs unhappy) and interaction styles (inclusive vs exclusive) on rapport building with community-dwelling older adults (aged 65 years or older). Using a gamified interaction paradigm, we focused on (1) the main effects of facial expressions and interaction styles on acceptance, rapport, rapport expectations, and trust; (2) the interaction effects of these 2 characteristics; and (3) the behavioral patterns exhibited by older adults during gamified human-robot interaction (HRI). By analyzing how older adults respond to both congruent and incongruent combinations of robot social cues, this research offers evidence-based guidelines for designing social robots that effectively support healthy aging.

Methods

Study Design

This study used a mixed-factorial experimental design with a 2 (facial expression: happy vs unhappy) × 2 (interaction style: inclusive vs exclusive) structure. Experimental condition (congruent vs incongruent assignment) served as the between-subject factor, whereas facial expression and interaction style were manipulated within participants. During task 2, each participant interacted with both robots, thereby enabling direct within-subject comparisons. This design allowed for the examination of both main effects and interaction effects. Participants were randomly assigned to 1 of 2 experimental conditions.

In the congruent condition (group 1), robot 1 exhibited a happy facial expression and inclusive interaction behavior, whereas robot 2 exhibited an unhappy facial expression and exclusive interaction behavior. In the incongruent condition (group 2), robot 1 exhibited an unhappy facial expression with inclusive interaction behavior, whereas robot 2 exhibited a happy facial expression with exclusive interaction behavior.

Ethical Considerations

This study was reviewed and approved by the Research Ethics Committee of National Taiwan University (202305HS096). All participants provided informed consent before taking part. All collected data were deidentified and stored securely. Participants received NTD 200 (NTD $1=US $0.03 as of July 6, 2026) as compensation for their participation. Upon completion of all

XSL•FO
RenderX

measures and the postexperiment interview, participants received a full debriefing that explained the experimental manipulation and clarified that the exclusive robot's behavior was experimentally scripted rather than contingent on the participants.

Participants

Community-dwelling older adults were recruited through volunteer networks at the university and through snowball sampling. The following inclusion criteria were established for participants: (1) age of 65 years or above, (2) normal cognitive function and hearing ability, (3) fluency in Mandarin to facilitate verbal interactions with robots, (4) normal or corrected vision adequate for perceiving robot facial expressions at a conversational distance, and (5) sufficient upper-body mobility to engage in game actions.

The sample comprised 53 participants, whose characteristics and experiences with robot interaction are detailed in Table 1. The average age of the participants was 70.57 (SD 4.27; range 65-85) years. The substantial majority (n=45, 84.9% of the participants) identified as female. Educational attainment varied among the group, with the largest proportion holding university degrees (n=22, 41.5%). Furthermore, most participants reported limited experience with robots, interacting with them less than once in the previous 6 months (n=44, 83%). Independent-sample 2-tailed *t* tests and chi-square tests indicated no significant differences between group 1 and group 2 on any baseline characteristics ($P>.10$ in all cases), supporting the success of the randomization procedure.

[a]Congruent condition (expression matched behavior).

[b]Incongruent condition (expression was mismatched with behavior).

[c]TIPI: Ten-Item Personality Inventory.

[d]Robot acceptance measured as total score (range 8-40).

[e]NARS: Negative Attitudes Toward Robots Scale (range 14-78; higher scores indicate more negative attitudes).

[f]HRI: human-robot interaction.

[g]SE-HRI: Self-Efficacy in Human-Robot Interaction Scale (range 10-60; higher scores indicate greater self-efficacy).

Apparatus

The study used Kebbi humanoid robots produced by NUWA Robotics (Figure 1). Each Kebbi robot stands at approximately 35 cm tall and is equipped with a wheeled base for mobility, articulated arms and elbows, and a touch screen face capable of conveying a wide range of emotions. In total, 3 Kebbi robots were used: 1 served as the neutral expression model for practice (designated as R0), whereas the other 2 participated in the main experimental task (referred to as R1 and R2). The robots were strategically positioned on a tabletop to ensure they were at eye level with the seated participants. Their behaviors were manipulated through the Wizard of Oz technique combined with the Message Queuing Telemetry Transport protocol to enable semiautonomous communication between the human users and the 2 robots.

XSL•FO
RenderX

Figure 1. Kebbi robot used in this study.

Experimental Task: Radish Squat Game

The experimental task was an adapted version of the Radish Squat game, which closely resembles the Cyberball paradigm used in research on social exclusion [22,23]. In this game, players take turns executing specific actions while verbally stating their identity and designating the next player. Actions are categorized into 2 groups: basic actions (raising a hand, nodding, and shaking the head) and advanced actions (flapping wings, hugging, and drumming). This format facilitates natural, repeated interactions while systematically controlling the dynamics of inclusion and exclusion.

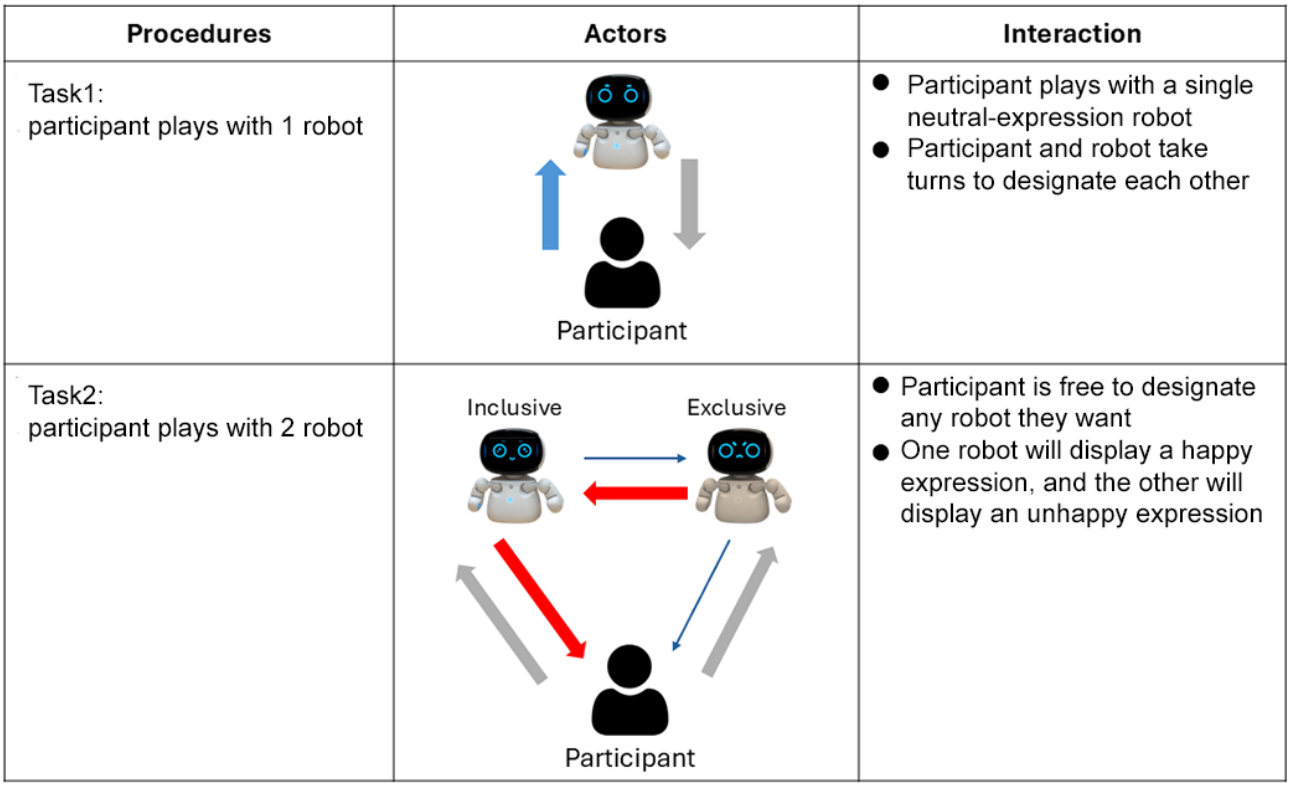
Manipulation of Independent Variables

Facial Expression

The robot's facial expressions were developed based on the elements associated with rapport as outlined by Wang and Gratch [20]. As depicted in Figure 2, the happy expression featured upturned corners of the mouth and a lifted chin, whereas the unhappy expression was characterized by furrowed brows, a wrinkled nose, and a raised upper lip. In the practice session, a neutral expression was used.

XSL•FO
RenderX

Figure 2. Robot facial expression designs.



Interaction Style

In accordance with established protocols [21,23], the inclusive robot designated participants 75% of the time while allocating 25% of the time to interaction with the other robot. Conversely, the exclusive robot designated participants only 25% of the time, dedicating the remaining 75% of the time to interaction with the other robot.

Procedure

The experiment consisted of 2 tasks (Figure 3). In task 1 (practice), participants engaged in the Radish Squat game with a single robot (R0) displaying a neutral facial expression for 12 turns to familiarize themselves with the task rules. In task 2 (main session), participants interacted simultaneously with 2 robots (R1 and R2), each exhibiting a distinct combination of facial expression and interaction style, over a total of 30 turns. The task 2 Radish Squat session lasted for an average of 12.4 (SD 2.1; range 9-17) minutes. Following task 2, participants completed postexperimental questionnaires and took part in brief semistructured interviews. The entire experimental session lasted approximately 45 minutes.

Figure 3. Experimental procedure flowchart.

Measures

Four dependent variables were assessed following interaction with each robot: robot acceptance, rapport, rapport expectation, and trust. Robot acceptance was measured using 8 items based on the technology acceptance model ([23,25]; item score range 1-5; higher scores indicate greater acceptance). Rapport was assessed using a 9-item rapport scale ([17]; Cronbach α=0.85; item score range 1-5; higher scores indicate greater rapport). Rapport expectation was measured using the 18-item Rapport-Expectation With a Robot Scale [26], comprising 2 subscales: expectation as a conversation partner (11 items; Cronbach α=0.85) and expectation for togetherness (7 items; Cronbach α=0.82; item score range 1-7; higher scores indicate greater expectation). Trust was assessed using the 15-item Trust Perception Scale–HRI ([27]; item score range 1-6; higher scores indicate greater trust). Behavioral data were collected as the number of times participants designated each robot during gameplay. Baseline measures included extraversion (Ten-Item

XSL•FO
RenderX

Personality Inventory [28]), empathy (Basic Empathy Scale [29]), negative attitudes toward robots (Negative Attitudes Toward Robots Scale [30]), and self-efficacy in HRI (Self-Efficacy in Human-Robot Interaction Scale [31]). Brief semistructured interviews were conducted after the experiment to gather qualitative insights regarding participants' interaction experiences and observations of robot behaviors. Table 2 summarizes all measures used in this study.

Table . Summary of measures.

Category and measure	Items, n	Scale	Reference

Statistical Analysis

A mixed-design repeated-measure ANOVA was conducted with facial expression (happy vs unhappy) and interaction style (inclusive vs exclusive) as within-subject factors and experimental condition (congruent vs incongruent) as the between-subject factor. Both main effects and interaction effects were analyzed for each dependent variable. Effect sizes were reported as partial η^2 and interpreted using the benchmarks by Cohen ([32]; small: $\eta^2 \geq 0.01$; medium: $\eta^2 \geq 0.06$; large: $\eta^2 \geq 0.1$). Post hoc power analyses ($\alpha = .05$) indicated adequate power for the detected interaction effects: for trust ($\eta^2 = 0.25$), achieved power was approximately 0.97; for rapport ($\eta^2 = 0.14$), power was approximately 0.83. Post hoc comparisons were performed using the Bonferroni correction. Additionally, paired 2-tailed *t* tests were used to compare the frequencies of behavioral designations between the robots ($t_{52} = 2.18$; $P = .03$).

Results

Manipulation Check

To conduct the postexperimental manipulation checks, each participant was interviewed to verify the successful implementation of both independent variables. With respect to facial expressions, chi-square tests indicated that participants correctly identified the happy-expression robot as displaying a happy expression at rates significantly above chance (N=53, $\chi^2_1 = 38.4$; $P < .001$) and the unhappy-expression robot as displaying an unhappy expression at rates significantly above chance (N=53, $\chi^2_1 = 31.7$; $P < .001$). Additionally, as shown in Table 3, the inclusive robot engaged participants significantly more frequently than the exclusive robot, further validating the behavioral manipulation.

XSL•FO
RenderX

Table . Frequency of robot designation by interaction style: manipulation check[a].

Robot type	Designations[b], mean (SD)
Inclusive	8.77 (1.73)
Exclusive	2.79 (1.79)

[a]t_{52}=24.31; P<.001.

[b]Designations refer to the number of times each robot designated the participants during task 2.

Descriptive Statistics

Table 4 presents descriptive statistics for all dependent variables across the 4 within-subject experimental conditions. The patterns were more nuanced than a simple summary of main effects would suggest. For acceptance, robots with happy expressions received higher ratings than those with unhappy expressions across both interaction styles, aligned with their high robot acceptance and HRI belief (Table 1). For rapport and trust, however, the advantage of happy expressions was concentrated primarily in the exclusive interaction condition, with only minimal expression-related differences under inclusive conditions. These patterns are elaborated on in the interaction analysis reported below.

Table . Mean scores of dependent variables by experimental condition.

Variable	Inclusive, mean (SD)	Exclusive, mean (SD)	Overall, mean (SD)
Acceptance (1-5)			
Happy expression	4.25 (0.54)	4.65 (0.41)	4.45 (0.52)
Unhappy expression	4.17 (0.65)	4.08 (0.74)	4.12 (0.689)
Rapport (1-5)			
Happy expression	3.74 (0.62)	4.44 (0.49)	4.08 (0.66)
Unhappy expression	3.88 (0.79)	3.77 (0.85)	3.82 (0.81)
Expectations as a conversation partner (1-7)			
Happy expression	4.33 (0.56)	4.85 (0.77)	4.58 (0.72)
Unhappy expression	4.41 (0.66)	4.01 (0.85)	4.20 (0.79)
Expectations for togetherness (1-7)			
Happy expression	4.81 (0.67)	5.65 (0.78)	5.22 (0.83)
Unhappy expression	5.07 (0.90)	4.54 (1.20)	4.80 (1.09)
Trust (1-6)			
Happy expression	4.48 (0.65)	5.13 (0.47)	4.79 (0.65)
Unhappy expression	4.55 (0.72)	4.66 (0.77)	4.61 (0.74)

Main Effects and Interaction Effects

Overview

Table 5 presents the results of the repeated-measure ANOVA. Facial expression demonstrated significant main effects across all 5 outcome measures, with effect sizes ranging from small to large. Interaction style significantly influenced rapport and both rapport expectation subscales. Significant interaction effects were observed for rapport and trust (both large effects), indicating that the combined influence of facial expression and interaction style was more complex than a simple additive pattern.

[b]Facial expression × interaction style.

[c]$P<.01$.

Acceptance

Facial expression had a significant main effect on acceptance ($F_{1,51}$=14.27; P<.001; η^2=0.22), with robots displaying happy expressions receiving higher ratings (mean 4.45, SD 0.52) than those displaying unhappy expressions (mean 4.12, SD 0.689). As shown in Figure 4A, the main effect of interaction style was not significant ($F_{1,51}$=3.18; P=.08; η^2=0.06), nor was the interaction between facial expression and interaction style ($F_{1,51}$=3.41; P=.07; η^2=0.06). In the absence of a significant interaction, the main effect of facial expression can therefore be interpreted directly.

Figure 4. Interaction effects of facial expression and interaction style. EMM: estimated marginal mean.

Rapport

For rapport, a significant interaction effect was observed ($F_{1,51}$=8.44; P=.005; η^2=0.14). In light of this interaction, the main effects were qualified and interpreted via simple effects. As shown in Figure 4A, 4B, and 4C, under exclusive interaction, the happy-expression robot generated substantially higher rapport (mean 4.44, SD 0.49) than the unhappy-expression robot (mean 3.77, SD 0.85). In contrast, under inclusive interaction, there was minimal difference between happy (mean 3.74, SD 0.62) and unhappy (mean 3.88, SD 0.79) expressions, and this difference was not significant following Bonferroni correction (P=.65). Thus, the advantage of happy facial expressions was concentrated in the exclusive condition. Accordingly, the overall main effect of facial expression ($F_{1,51}$=6.69; P=.01; η^2=0.12) and the main effect of interaction style ($F_{1,51}$=6.22; P=.02; η^2=0.11) should be understood as being driven by this asymmetry rather than uniform effects across interaction conditions.

XSL•FO
RenderX

Rapport Expectation

Regarding expectations for a conversation partner, both facial expression ($F_{1,51}$=11.34; P=.001; η^2=0.18) and interaction style ($F_{1,51}$=7.99; P=.007; η^2=0.14) exhibited significant main effects, whereas their interaction was not significant (Figure 4C; $F_{1,51}$=0.29; P=.59; η^2=0.01). As shown in Table 4, robots with happy expressions elicited higher conversation partner expectations (overall mean 4.58, SD 0.72) than those with unhappy expressions (mean 4.20, SD 0.79), and exclusive robots elicited higher expectations (marginal mean 4.43) than inclusive robots (marginal mean 4.37). In the absence of a significant interaction, these main effects can be interpreted directly.

For togetherness expectations, both facial expression ($F_{1,51}$=10.28; P=.002; η^2=0.17) and interaction style ($F_{1,51}$=10.47; P=.002; η^2=0.16) yielded significant main effects, with no significant interaction ($F_{1,51}$=0.41; P=.52; η^2=0.01). Robots with happy expressions elicited higher togetherness expectations (overall mean 5.22, SD 0.83) than those with unhappy expressions (mean 4.80, SD 1.09). As shown in Figure 4D, although inclusive robots tended to elicit lower togetherness expectations than exclusive robots within the happy-expression condition, this pattern did not reach the level of significant interaction.

Trust

For trust, a significant interaction effect was observed ($F_{1,51}$=16.62; P=.002; η^2=0.25). As shown in Figure 4E, under exclusive interaction, the happy-expression robot received substantially higher trust ratings (mean 5.13, SD 0.47). Under inclusive interaction, the pattern was slightly reversed: trust ratings for the happy-expression (mean 4.48, SD 0.65) and unhappy-expression (mean 4.55, SD 0.72) robots were essentially equivalent, and this difference was not significant following Bonferroni correction. The significant main effect of facial expression ($F_{1,51}$=4.36; P=.04; η^2=0.08), therefore, reflects the strong expression effect in the exclusive condition. The main effect of interaction style was not significant overall ($F_{1,51}$=2.91; P=.10; η^2=0.05).

Behavioral Patterns: Designation Frequency

The analysis of behavioral data unveiled an unexpected pattern in the designation behavior of participants (Table 6). Contrary to established expectations, participants designated the exclusive robot significantly more frequently than the inclusive robot. This finding stands in contrast to earlier research with university students, who tended to favor the inclusive robot [23]. Qualitative interview data suggested that participants' designation behaviors were guided primarily by considerations of fairness and turn taking.

Table . Participants' designation frequency during task 2[a].

Target robot	Designations, mean (SD)	Total designations, n
Inclusive interaction	5.32 (2.12)	282
Exclusive interaction	6.42 (1.84)	340
Happy expression	6.09 (2.06)	323
Unhappy expression	5.64 (2.04)	299

[a]Inclusive vs exclusive: t_{52}=2.18 (P<.05); happy vs unhappy: t_{52}=0.87.

Representative interview quotes illustrating fairness-based designation strategies included the following:

> *I wanted to ensure fair turn-taking so everyone could participate.* [G1-17-F]
>
> *Since the blue robot kept choosing the red robot, I designated blue to make it fair.* [G2-16-F]
>
> *I simply picked them in turns to give everyone a chance to play.* [G1-4-F]
>
> *I assigned both robots because I believe the game should involve taking turns.* [G2-1-M]
>
> *I chose randomly since we were playing together and wanted everyone to have their turn.* [G1-26-M]

These responses suggest that older adults actively sought to balance the exclusive robot's behavior. They consistently used turn-taking strategies to maintain fairness and equitable participation, including for the robots themselves.

Discussion

Principal Findings

This study examined how a robot's facial expressions and interaction style affect the development of rapport between older adults and social robots. Our findings revealed that (1) positive facial expressions significantly enhanced acceptance, rapport, rapport expectations, and trust; (2) an inclusive interaction style contributed to improved rapport and heightened rapport expectations; (3) there were notable interaction effects between facial expression and interaction style on both rapport and trust; and (4) older adults demonstrated a strong tendency toward inclusivity regarding robots, actively compensating for any behaviors that may seem exclusive.

Comparison With Prior Work

Our findings regarding the impact of facial expressions are consistent with those of prior research indicating that positive robot expressions enhance the quality of interactions [19,33]. The observed effect sizes (η^2=0.08-0.22) point to medium to

XSL•FO
RenderX

large effects, underscoring the importance of facial expression as a significant cue for older adults in rapport building.

The interaction effects between facial expression and interaction style represent a novel theoretical contribution. Under inclusive conditions, the robot's behavior reliably signaled social engagement and satisfied CASA-derived expectations for turn taking and politeness norms [12,13]. This behavioral sufficiency may attenuate reliance on facial expression as a diagnostic cue. Under exclusive conditions, however, the behavioral signal was ambiguous or negative, creating a cue vacuum that heightened the diagnostic value of facial expressions as participants sought to infer the robot's social intentionality. The large interaction effect for trust (η^2=0.25) is particularly noteworthy: trust in the exclusive robot was substantially modulated by facial expression, whereas trust in the inclusive robot remained relatively stable regardless of expression. This pattern aligns with the extension of CASA by Gambino et al [12], which posits that, when behavioral signals deviate from social norms, people rely more heavily on secondary cues such as appearance. Incongruent combinations (positive expression+exclusive behavior) appeared to intensify attention to facial cues as participants attempted to interpret the robot's intentions, a process that, in this sample, ultimately yielded higher rapport with and trust in the happy-faced exclusive robot, suggesting that positive expression may partially compensate for exclusive behavior [23]. Future research using mediation designs could formally test the proposed attentional pathway.

Notably, older adults designated the exclusive robot more frequently than the inclusive robot, in stark contrast to university students in earlier research [23], who favored the inclusive robot. This generational difference may reflect divergent values related to fairness and group harmony. In the socioemotional selectivity theory by Carstensen [34], older adults prioritize emotionally meaningful relationships and prosocial goals. This orientation may lead them to perceive the exclusive robot as a social agent in need of remediation and actively compensate through equitable turn assignment. This pattern is also consistent with prosocial aging research documenting heightened concern for fairness among older adults [24,35]. Future studies using more gender-balanced samples would be valuable for determining whether this inclusivity tendency is particularly characteristic of older women, who constituted the majority of our sample.

Implications for Healthy Aging Interventions

These findings carry important implications for the design of social robots that support healthy aging. First, positive facial expression capabilities appear essential as they produced medium to large enhancements across a range of rapport-related outcomes. Second, designers should prioritize inclusive interaction behaviors that actively engage older users. Third, the observed interaction effects indicate that optimizing individual features in isolation may not yield optimal combined outcomes. The mutual amplification of facial expression and interaction style, particularly in exclusive contexts, needs to be considered from a holistic design perspective.

From a public health standpoint, the demonstrated capacity of older adults to establish rapport with robots through brief, gamified interactions underscores the feasibility of scalable robot-mediated interventions. Moreover, the finding that older adults viewed robots as entities deserving of equitable treatment highlights the potential for meaningful human-robot relationships to complement human care in addressing loneliness and social isolation [36].

Limitations

This study offers valuable observational insights; however, several limitations warrant careful consideration. First, our sample was predominantly female (45/53, 84.9%), likely reflecting recruitment through university-affiliated volunteer networks in Taiwan, which tend to overrepresent women among older adults. Because gender can influence social cue processing and trust building in HRI [30,37], the present findings may be more directly applicable to older women. Future studies with more gender-balanced or male-majority samples are needed to assess generalizability. Second, the gamified Radish Squat interaction enabled precise experimental control but may differ from naturalistic caregiving contexts in duration, emotional stakes, and task demands. The rapport captured in this study reflects initial formation in a brief, structured setting; whether these patterns persist and predict rapport stability in long-term caregiving relationships requires longitudinal investigation [38]. Nonetheless, gamified formats are increasingly adopted in health-promoting robot interventions for older adults, lending direct relevance to the present findings. Third, the single-session design precludes conclusions about long-term rapport development or the cumulative effects of repeated exposure. Additionally, our focus on healthy, community-dwelling adults suggests that the findings may not be applicable to individuals with cognitive impairments. Future research could benefit from systematically examining gender differences, using longitudinal designs, and investigating the cognitive and neurobiological mechanisms that may underpin older adults' strong inclusivity responses toward robots.

Conclusions

This study demonstrates that gamified interactions can effectively foster rapport between older adults and social robots. Positive facial expressions and inclusive interaction behaviors enhanced acceptance, rapport, rapport expectation, and trust. Crucially, these elements interacted synergically: the positive impact of happy facial expressions was substantially amplified when the robot behaved exclusively, suggesting a context-dependent cue-weighting process grounded in the CASA paradigm [12]. The unexpected finding that older adults compensated for exclusive robot behavior through fairness-based turn taking further suggests that they perceived these robots as social entities worthy of equitable treatment. Collectively, these insights offer evidence-based design guidelines for social robots intended to foster meaningful relationships with older adults and contribute to the development of technology-based interventions that promote healthy aging.

Abstract

Background: The COVID-19 pandemic highlighted how restrictions on in-person interactions within long-term care homes (LTCHs) severely compromised social connectedness among older adults and their families. Post pandemic, despite policy changes supporting greater in-person family engagement, frequent outbreaks continue to disrupt face-to-face interactions, and factors such as geography, life circumstances, and health can constrain family members' ability to make regular in-person visits. Research suggests that web-based videoconferencing technology (WVT) may be a practical solution to help older adults within LTCHs to maintain social connection in the absence of physical gathering. However, increased understanding of end user experience is lacking, and more information on LTCHs' readiness to support and sustain WVT will be needed if this modality is to be successfully and widely implemented.

Objective: This study aimed to understand how older adults living in LTCHs, their families, and LTCH staff members perceived the use and ease of use of WVT devices for facilitating social connectedness.

Methods: Using a qualitative description approach, in-depth semistructured interviews were conducted with 7 older adults, 22 family members, and 10 staff across 3 LTCHs via Zoom (Zoom Communications, Inc), Microsoft Teams, or phone calls. Data were analyzed using a directed content analysis informed by the technology acceptance model.

Results: Findings were structured into 3 main themes: actual system use, perceived usefulness of WVT, and perceived ease of use of WVT. Participants described using a range of WVT hardware and software to promote social connection between older adults and family members. Videoconferencing had a crucial role in supporting older adults and their family members' positive emotional state while also enabling them to maintain life and social roles such as participating in family functions. Despite the perceived use of these tools, participants were concerned about the decline in offering videoconferencing services across LTCHs post pandemic. Some participants noted shifting funding priorities toward supporting in-person recreational activities rather than diversifying web-based social connection options. In addition, factors pertaining to WVT ease of use and integration included limited staff to support older adults with different physical and cognitive needs, variability in digital literacy including knowledge about accessibility features to enhance the ease of use, and families' lack of awareness about the availability of WVT for social connectedness.

Conclusions: Web-based videoconferencing technology has the potential to be a meaningful tool to reduce social isolation and promote a sense of social connectedness among older adults and their families and friends. Future research should explore how WVT could be integrated into care planning for this population, particularly in situations where older adults may be at heightened risk for social isolation. Resource allocation toward equipment, infrastructure, and family and staff training would be well-placed to increase engagement with WVT within LTCHs.

Introduction

Background

Globally, the COVID-19 pandemic impacts were profound, causing widespread loss of life and morbidity [1,2]. During the earliest phases of the pandemic, significant restrictions were placed on many social activities, including normal activities of daily living (eg, shopping and leisure activities) [3-8]. One specific aspect of daily living that was significantly affected included the notion of *social connectedness* [9,10]. Social connectedness can be described as the subjective sense of being in close-knit relationships with others [11,12]. Having interpersonal relationships and being able to gather with others are integral to individuals' health and well-being [13,14]. These avenues for social connectedness can prevent people from feeling lonely and reduce the risk of impaired mental health [14-21]. Canadian older adults residing in long-term care homes (LTCHs) were disproportionally affected by the lack of in-person interactions or access to social spaces over the course of the pandemic [22], resulting in their compromised social and emotional well-being [22-24].

During the height of the COVID-19 pandemic, various web-based videoconferencing technologies (WVTs) were introduced by LTCH staff and family members to help maintain social connectivity between older adults residing in LTCHs and their social circles [25-29]. Leveraging WVTs to facilitate social connectivity among older adults was particularly beneficial as these individuals were at greater risk of isolation and loneliness due to factors such as pre-existing isolation (eg, living alone), being reliant on family for support, and impaired physical health such as frailty [30]. Web-based videoconferencing, the use of networked digital telecommunications technology, is a form of telepresence that "simulates the experience of being physically present in a remote environment" [31]. FaceTime (Apple, Inc), Skype (Microsoft Corp), or Zoom (Zoom Communications, Inc) are among the most popular videoconferencing applications used to continue communication among older adults and family or friends when in-person gatherings are restricted [26,32]. Using WVTs enabled people to visually interact with their family members and, in addition to hearing their voice, offered a greater reassurance of their well-being through a visual confirmation [29]. In addition, seeing older adults within LTCHs using WVTs can help foster family members' belief that their family member was well-cared for [33].

Research suggests that web-based videoconferencing is a viable form of connection for people living in long-term care who may be physically separated from their families and familiar social settings (eg, religious mass services and health care consultations) [34-39]. However, there remains a lack of insight pertaining to the experiences of the individuals directly using this technology. Moreover, additional research is required to inform sustainable and consistent use of WVTs as a reliable option to help older adults maintain social connectedness [40]. Although WVTs offer clear benefits, some literature suggests that this technology may cater more to family members than older adults living in LTCHs, especially if the older adult lives with some degree of cognitive challenge (eg, dementia) [28,33,41]. The types of benefits offered by WVTs across a range of users for the purposes of fostering social connection necessitate further exploration, particularly among older adults with varied cognitive abilities residing in LTCHs. As such, greater knowledge is required to understand how older adults with both physical and cognitive impairments may benefit from or experience challenges in using WVTs [33]. Furthermore, there is a need to understand if and how LTCHs are positioned in terms of infrastructure and staffing to support successful widespread WVT use. For example, arthritis, vision impairments, or neurodegenerative conditions such as Parkinson disease could necessitate the need for adaptive technology or additional assistance as well as greater staff requirements and ultimately cost for the LTCH [42,43]. The potential benefits of WVTs as a tool to support social connection have been shown, but within LTCHs, there is a need to better understand end user experiences if it is to be successfully integrated and sustained as a widespread tool to support social connectedness.

Objective

The purpose of this study was to understand how older adults living in LTCHs, their families, and LTCH staff members perceived the use and ease of use of WVTs as viable modalities for facilitating social connectedness.

Methods

Project Registration

This study presents the findings of the first stage of a multistage qualitative research study described in the published protocol [44].

Study Design

Using a qualitative description methodology [45], this study sought to explore how older adults in LTCHs, their family members, and LTCH staff experience and understand the use of WVTs to support the social connectedness of older adults in LTCHs. Qualitative description methodology enables researchers to capture and describe a wide range of participants' experiences and perceptions in a comprehensive, yet clear and practical way using in-depth interviews with study participants [45,46]. In addition, qualitative description is a low-inference approach used in social sciences and health care to provide researchers with a practical way to derive rich, close to data descriptions of participant experiences without the need to interpret the meaning of participant experiences [46]. In addition to in-depth interviews, observational field notes were kept throughout this study, thereby enhancing the dataset and the overall study rigor [47]. Studies using qualitative description methodology seek to find answers that are of high relevance to practitioners or policymakers to improve the quality of a delivered service, including participants' thoughts or attitudes toward a service; why do participants use certain services more so than others; and how participants use a service in specific instances [45,48].

Theoretical Framework

The technology acceptance model (TAM) [49] was used to shape interview questions and to organize and report qualitative

XSL•FO
RenderX

findings in this study. TAM is a widely used model that helps researchers uncover how end users adopt the use of technological systems and how this adoption is influenced by constructs such as usefulness and perceived ease of use [50]. According to TAM, the actual system use construct concerns the observable use of technology [49] and, in the context of this study, refers to the use of WVTs by the study participants (older adults, family members, and staff in LTCHs) for the purpose of social connection. The perceived usefulness construct is the extent to which technology end users perceive technology as enhancing their tasks or helping them achieve a particular goal [49]. In this study, perceived usefulness is the degree to which participants believe that WVT (devices and software) facilitates social connectedness or makes it more meaningful. The perceived ease of use construct pertains to the amount of effort required to operate the technology by end users [49] and, in this study, reflects participants' perceptions of how simple it is to operate or navigate WVTs to engage in video calls with friends and family members.

A range of open-ended interview questions was developed using the TAM constructs to guide the in-depth interviews with study participants. For a full list of interview questions, please see Multimedia Appendix 1 in our protocol [44]. In line with qualitative descriptive methodology supporting the use of deductive approaches (ie, TAM) to guide data analysis [51,52], this study presents descriptions of participants' experiences organized under the following TAM constructs: the (1) *actual system use*, (2) *perceived usefulness*, and (3) *perceived ease of use*.

The Use of TAM With Qualitative Description Approach

Findings grounded in qualitative description methodology result from staying close to the words and events in the research data capturing straightforward descriptive accounts of participant experiences [45,46]. In some qualitative descriptive studies, findings are categorized under constructs of a chosen theoretical framework [51]. This study incorporated TAM as a framework for organizing data-driven coding and practical and identifiable constructs of the TAM that may be of use to policy makers. The process of incorporating TAM into the data analysis phase ensured that participant data were organized and described in a structured way without imposing subjective interpretations or other theoretical assumptions on the data. Such an approach aligns with previously published research that successfully integrated TAM with qualitative description methodology to describe older adults' adoption of digital modalities [51,53,54].

Sample

The desired sample size for qualitative description studies is influenced by factors such as the subject or phenomenon of interest, its representation within the broader population, and the potential variability of experiences with the phenomenon [55]. As such, the recruitment goal of this study was 45 individuals comprised of 3 groups: older adults residing in LTCHs, their family members, and associated staff from 3 participating LTCHs located in southwestern Ontario, Canada. Eligible participants were English-speaking individuals with mild to moderate cognitive disability and able to participate in an interview using the Zoom or Microsoft Teams videoconferencing platforms or a phone. Potential older adult participants with mild cognitive decline living in LTCHs were assessed [56] for suitability to participate in this study by a member of their circle of care within the LTCHs before any study information was shared with them.

Ethical Considerations

This study was reviewed and approved by the Western University Research Ethics Board (2024-121993-91059). Participants were informed about the research study, and their questions were answered by the study research assistant before they consented to participate. Collected data was anonymized and participants who completed an interview were given a $10 (CAD or $7.20 USD) gift card as an honorarium.

Recruitment and Data Collection

Participant recruitment and data collection took place between July 2023 and January 2024 using purposeful and maximum variation sampling to help ascertain a sample with a variety of experiences with WVTs, especially among the older adult and family member participants. Research information was distributed to prospective participants via on-premises physical posters, emails, LTCH newsletters, and word of mouth. Individual in-depth interviews with older adults, their family members, and LTCH staff were offered in person, via phone, or by Zoom videoconferencing to accommodate individual preferences and took place at an agreed-upon date and time. Recreational therapy department staff or a family care partner assisted older adult participants in joining the Zoom or interview if necessary. Interviews with participants were audio recorded and transcribed verbatim prior to analysis.

Data Analysis

The collected data were anonymized and analyzed using NVivo (version 13; Lumivero) qualitative analysis software [57] and directed content analysis, a qualitative analytic technique characterized by a structured stepwise process of coding the data and organizing it into categories and themes [58,59]. The first step of the data analysis entailed deidentification of the cases. Interviews collected from family members were assigned identification such as FM followed by the number of the participant (FM01, FM02, and so on). Similarly, older adults were assigned identification of OA (OA01, OA02, and so on), and staff participants were assigned identification S (S01, S02, and so on). The next step involved reading the interview transcripts, developing memos, and noting down compelling quotes. A formative coding framework was then developed based on the TAM constructs with consensus reached through discussion of the research team. The key constructs of the TAM, perceived usefulness and ease of use of technology, served as initial codes or units of analysis. Data that did not lie within one of the key codes were labeled with a new code and organized into new categories or as subcategories under the initial codes [58]. The preliminary coding framework was tested against the same 5 interview transcripts. Researchers then met on a biweekly basis to refine the coding framework by establishing links between generic and main conceptual categories. The newly identified codes were compared and

XSL•FO
RenderX

discussed for similarities and differences until consensus was reached regarding the emergent patterns as the concepts became more densely packed with meaning and evidence. Study rigor was ensured through conducting member checking [60], acknowledging biases researchers may introduce to the research and practicing reflexivity throughout the research processes, and ensuring confirmability of data through triangulation between interviews and field notes [61].

Results

Demographic Characteristics Overview

The total sample comprised 39 participants, which is congruent with sample sizes in other studies using qualitative descriptive methods [51]. The sample included older adults (n=7, 18%), family members (n=22, 56%), and staff (n=10, 26%) from 3 participating LTCH facilities, offering diverse perspectives on WVT use in these settings. The 3 participating homes were licensed, not-for-profit LTCHs spanning 120 kilometers and providing comprehensive care to between 160 to 394 individuals, including an emphasis on person-centered care.

All 7 (18%) older participants were female and aged between 64 and 95 years. Older participants were widowed (28/39, 71%) or divorced (11/39, 29%). All 39 older adults either had a college diploma (n=22, 57%) or a university degree (n=16, 42%), providing some context that may be related to the ease of using WVTs. The majority of older adults (n=28, 71%) reported living with cognitive or physical challenges (eg, poststroke impairment, dementia, and arthritis), which provides essential context for understanding the impact of cognitive or physical limitations on WVTs' usefulness, ease of use, and intention to continue using WVTs. Moreover, 31 out of 39 (nearly 80%) participants in this study identified that physical (eg, arthritis) or mental disability (eg, dementia) affected individuals' ability to use WVTs.

The 22 family members (FMs) consisted of 18 female and 4 male participants, and were aged between 40 and 69 years. Many family members held a university bachelor's degree (16/39, 41%), with a notable portion being retired (14/39, 36%).

All 10 staff participants were female, with just under half (10/39, 40%) working in their profession between 6 and 10 years. Staff participants included a range of health professionals such as recreational therapists (12/39, 30%), social workers (8/39, 20%), personal support workers (8/39, 20%), a registered practical nurse (4/39, 10%), and a spiritual care practitioner (4/39, 10%).

Thematic Presentation of the Findings

Overview

Study findings on participants' roles (older adults, FMs, and staff) and experiences in using WVTs for the purpose of social connectedness are presented in themes informed by the TAM and include the actual system use, with 2 subthemes—(1) WVTs' hardware and software and (2) trajectory of using WVTs from pre- to postpandemic; perceived usefulness, with 4 subthemes—(1) enabling remote connection, (2) providing emotional and psychological benefits, (3) fostering continuation of life and social roles, and (4) the enriching effect of video presence; and perceived ease of use, with 3 subthemes–(1) design and practicality of the devices and platforms used, (2) usability and accessibility of the devices, and (3) impact on the workload (Textbox 1).

Textbox 1. Summary of technology acceptance model–informed themes and subthemes.

Theme 1: actual system use

- Web-based videoconferencing technologies' hardware and software
- Trajectory of using web-based videoconferencing technologies from pre- to postpandemic

Theme 2: perceived usefulness of web-based videoconferencing technologies

- Enabling remote connection
- Providing emotional and psychological benefits
- Fostering continuation of life and social roles
- Enriching effect of video presence

Theme 3: perceived ease of use of web-based videoconferencing technologies

- Design and practicality of the devices and platforms used
- Usability and accessibility of the devices
- Impact on the workload

Theme 1: Actual System Use

Overview

The actual system (WVTs) use theme consisted of 2 subthemes: (1) the hardware and software used by older adults, FMs, and staff, and (2) WVTs use trajectory from pre- to postpandemic timeframes.

WVTs' Hardware and Software

During the pandemic, LTCH staff introduced iPads and tablets as a virtual means to facilitate social connectedness between families. Older adults and families also used a range of personal

XSL•FO
RenderX

devices with videoconferencing capabilities such as iPads or tablets, laptops, computers, smartboards, and smartphones. Moreover, some families independently researched and purchased nontraditional devices that FMs suggest have more merit for people with physical or cognitive conditions (eg, dementia, arthritis, and paralysis) to access the WVTs they were using, namely, Portal, Alexa Echo Show, and ViewClix hardware. Participants also used various software platforms for WVTs, including Zoom, Teams, WhatsApp, Skype, Facebook Messenger, Signal, and FaceTime (Table 1).

Table . Web-based videoconferencing technologies used across study participants (N=39).

Web-based videoconferencing technology	Older adults, n	Family members, n	Staff, n	Total, n
Hardware types				
iPad or tablet	6	15	10	31
Computer	3	6	1	10
Laptop	0	4	2	6
Smartboard	0	0	2	2

Trajectory of WVT Use From Pre- to Postpandemic

The iPads or tablets were predominantly leveraged by LTCHs' recreational department teams during the pandemic-related lockdowns and resultant restrictions on in-person visitations as an alternative to socially connect FMs and older adults residing in LTCHs. However, post pandemic, this service was not unanimously integrated into LTCHs' care delivery. Some LTCHs have embraced the technology, integrating it into daily routines or care planning, while others have shifted funding priorities toward in-person recreational activities, which some FMs shared were not always as meaningful as the ability to see and interact with their loved ones on the screen.

Participants reported varied knowledge of acceptance and normalization of WVT use across different LTCHs from pre- to postpandemic. Most participants who used WVTs to socially connect with people outside LTCHs prepandemic continued to do so during and post pandemic. For these participants, it was the only way to connect with family who lived abroad or far away from LTCHs.

Among the study participants, 14 (36%) participants stated they began using WVTs to support social connectedness due to the pandemic (7 FMs, 5 staff, and 1 older adult). Eleven (28%) participants shared that WVTs continue to be offered by the LTCHs or that they still use it post pandemic (6 FMs, 3 staff, and 1 older adult), while 10 (26%) participants believe the service has stopped being offered post pandemic by the LTCHs (5 FMs, 3 staff, and 1 older adult). A few reasons were provided by the participants to explain the decline in use post pandemic. First, a shift of priorities to do more in-person activities and visitations resulted in a lack of recreational department staff support to help with videoconferencing service. As 1 FM whose mother was admitted to LTCH in March 2023 shared:

> *I've never had it offered to me with my mom. I don't think the emphasis is on it and part of it is because the reason they had time to do more of that [videoconferencing] was because so many other programs were cancelled, right?* [FM21]

A second reason provided was a lack of awareness among older adults and their family members that connecting socially using WVTs was still being offered in the LTCHs:

> *If they have anything to offer, they're certainly not advertising it, I think they don't have it. I think that it was simply cut.* [FM19]

A similar concern was echoed by a staff member participant:

> *I don't even know how much recreation [department] even does help with Zoom calls anymore because all family – like anybody can come in now, right? Or they just call too, right? I don't really see much Zoom,*

XSL•FO
RenderX

> *FaceTime, or anything anymore with residents really.* [S07]

The third identified contributor to the decline of WVT use post pandemic shared by the participants was related to the workload challenges imposed by supporting the use of WVTs to socially connect people:

> *We just simply don't have that manpower to be engaging in this environment as well as supporting you to have a conversation with someone. Even though we understand the value in that, and how important that is for their emotional health, you know, when they are feeling positive and good and they know that their family is safe, they don't have responsive behaviours.* [S02]

In summary, the use of WVTs in LTCHs demonstrated benefits for maintaining social connectedness during the pandemic. However, the transition to postpandemic society revealed a decline in its continued use and only partial normalization of videoconferencing across the 3 LTCHs in this study. The trajectory of WVT use from pre- to postpandemic provides insights into the fluid role that technology can have in supporting social connectedness of older adults in long-term care settings.

Theme 2: Perceived Usefulness of WVTs

Overview

The perceived usefulness of WVTs for social connectedness is represented by 4 subthemes: enabling remote connection, providing emotional and psychological benefits, fostering continuation of life and social roles, and the enriching effects of video presence.

Enabling Remote Connection

WVTs enabled residents to connect remotely with family and friends, thereby bridging physical distances that in some cases were difficult for FMs to overcome. This opportunity was particularly important for those families who lived at a great geographical distance from the LTCHs or were unable to visit frequently due to various constraints:

> *We'll FaceTime with family members that are far away. I mean, last year, we were basically in four different time zones. My sister was Central, I'm Eastern, my daughter was in the U.K. and one of my nephews was in Japan.* [FM09]

Conversely, another participant noted a robust example of how WVTs could connect people in the same building:

> *At one point [my parents] had to be separated and put on separate floors, so we used a lot of FaceTime and – is it Facebook Messenger? Yes, we were using that between the two of them. So, two of us would have to go in every day and one to my father, one to my mother, so that the two of them could talk.* [FM03]

In addition, videoconferencing was a useful tool that enabled family to note health care–related details in older adult's presentation, which they later communicated to the staff, as shared by this FM:

> *I recognized when she had an eye infection, or I could see that her hands were really dry. I couldn't have done that if I was on the phone. We were able to see things and it informed us more about how my mother really was, and it improved her care.* [FM18]

WVTs were also used for accessing care as an accessible alternative in place of the traditional in-person meetings:

> *For the annual team meetings, we had the option to do that virtually or in person. And my sister doesn't drive, and the care home is a long way from her place, so she chose to meet with the care staff virtually, which she really appreciated.* [FM02]

Those who have not used WVTs for health care access expressed receptiveness to this possibility (FM12). However, those FMs who lived within proximity to the LTCH preferred in-person meetings for such matters. For instance, 1 FM shared that*:*

> *there is an annual health care review, and they might have offered that as an option, but I'm just ten minutes from where my mum is, so you know, I would just come in for that meeting.* [FM16]

Another FM raised an interesting point regarding the nonverbal communication that takes place during the in-person meeting that can be missed or hard to sense over the video call:

> *In-person you sense if there's anything going on. You sense it more because when you are videoconferencing, you may see just one person at a time. But when you're sitting in the room, we're all sitting around, and I see everybody, and you feel something if there's something wrong, if they're not telling you everything. On videoconferencing you can't feel it. You just see it, but you don't feel like there's any issues.* [FM22]

These quotes exemplify how WVTs ensured continuous social engagement, helping many residents feel less isolated and more connected to the outside world during lockdown or when they were in isolation.

Providing Emotional and Psychological Benefits

Regular videoconferencing interactions helped support older adults' mental health by reducing feelings of loneliness and isolation. The web-based presence connection with family and friends was a vital source of emotional support. Older adults and their FMs experienced substantial emotional benefits from connecting through the video call via WVTs. It provided them with comfort, joy, and a sense of connectedness, which heightened their positive emotional and psychological well-being:

> *The biggest thing it helps with is their mental health, especially if they're just making that change into long-term care. Or if they've been in there, to help lift them out of some bad times or bad moments, because I know that depression in long-term care is huge. There's 24 hours in a day, and if they're sleeping 10 hours and they only get four hours devoted time from someone, there's a lot of time in between there. So, if there could be some way that*

XSL•FO
RenderX

> *they could speak to friends or family or anyone else more, then I think it would decrease depression in long-term care. And that would be big.* [FM07]

Other examples of the ability of WVTs to provide emotional and psychological benefits include its potential to anecdotally delay the decline associated with a chronic disease such as dementia:

> *I think, for the dementia and Alzheimer's, for her [mom] to visually see the relatives on whatever we use, whether it's Zoom or FaceTime or Portal, and connect the face with the voice has sort of delayed her [mom's] decline, because you can actually see them.* [FM09]

In addition, WVTs were used for prevention of responsive behaviors associated with dementia:

> *They [staff] proactively call, because they figure it'll help settle her [mom] down. So now they do FaceTime because they obviously realize that if she [mom] can see somebody then it calms her down even more than just a telephone call.* [FM09]

Fostering Continuation of Life and Social Roles

Fostering continuation of life and social roles was another subtheme associated with WVT use. For example, WVTs provided an avenue to maintain a sense of normalcy by allowing older adults to continue participating in daily life activities and social roles beyond LTCH walls. For instance, older adults kept in touch with FMs and things that were meaningful to them (eg, their pets), remained updated on family events, and engaged in routine conversations that they would typically have in-person prior to being admitted to LTCHs:

> *I was trying to keep [mom] updated, how her pet was doing... show her visually–I would take her for a walk, through the gardens.* [FM07]

Participants found WVTs useful because they allowed them to fulfill their roles as parents, grandparents, and friends. Even if through the screen, they could still offer advice, participate in family decisions, and stay involved in the lives of their loved ones.

In addition to continuing to fulfill their social roles within the family and household, WVTs allowed older adults to participate in other social events. For example, 1 staff member described how WVTs were used for facilitating music concerts for older adults*:*

> *We would get music entertainers at home through video chat and each home area would have on their smart board to get the video chat going.* [S03]

Another example was using videoconferencing to stream mass in churches facilitated by a spiritual care practitioner (1 staff). As a result, 1 older adult requested to attend a virtual mass daily, as it allowed this resident to feel connected to a church community they belonged to prior to the pandemic. These examples demonstrate the expanded role of WVTs in fostering a sense of connectedness with other community members.

Enriching Effects of Video Presence

Compared to other means of communication (eg, landline phone), WVTs were described as having an enriching effect on social connectedness. Participants shared that being able to see faces, share visual experiences, and express emotions more vividly via the screen contributed to a deeper sense of connection:

> *How many times you read an email where you take it wrong. How many times you get on a phone, and you don't understand a person may be sounding angry, but they're visually upset. I think the video adds a lot in those situations, particularly since in a nursing home it is so emotional.* [FM01]

In addition to the interactions between family and older adults, participants described how videoconferencing allowed them to record interactions and watch them later or send them to others (FM01) or observe the resident-staff interactions:

> *A side benefit is, every so often I'll catch one of the staff members in the room with him [my husband], so I have a nice chat with the nurse. I live next door, so I'm there all the time anyway, but it gives me a chance to see the interactions between him and the staff.* [FM17]

In summary, these findings underscore the multifaceted usefulness of WVTs in maintaining social connectedness and well-being not just for older adults, but also for FMs. Usefulness of WVTs may be hindered or enhanced based on how intuitive and user-friendly these technologies are for older adults, FMs, and LTCH staff.

Theme 3: Perceived Ease of Use of Web-Based Videoconferencing Technologies

Overview

The perceived ease of use was informed by 3 subthemes: design and practicality of the hardware and software, usability and accessibility of the WVTs, and ease of use in relation to the impact on the workload for staff members supporting WVT use.

Design and Practicality

Factors impacting the external design of the devices, such as size of the screen, weight, and the availability of supportive accessories like stands, iPad covers, stylus, external speakers, and headphones influenced the practicality and ease of use of WVTs for older adults.

Hardware devices with larger screens, clear audio, and simplified navigation were reported as easier to use. Accessories like headphones or speakers also improved the ease of use. Participants also benefited from using devices with software interfaces requiring minimum to no effort to operate:

> *With our mom, she didn't have to know anything, she just would see faces pop up.* [FM04]

Portable hardware devices were preferred by some, as they could be conveniently moved and adjusted according to the residents' needs and preferences and provided more privacy (4 staff). For instance, 1 FM described how they enjoyed going

XSL•FO
RenderX

for a walk into the garden and video calling their family from that location. At the same time, portability potentially breached privacy when residents were situated in an open public space like the dining area due to a lack of private space or convenience for staff (1 FM and 2 staff). Eight (21%) participants also expressed their concern for device misplacement, theft, or a risk of accessing passwords and private information through older adults' personal devices (1 older adult, 5 FMs, and 2 staff), which could be amplified by the devices' portability.

Usability and Accessibility

The usability and accessibility of the devices were key factors impacting participants' use of WVTs. In this study, 31 out of 39 (nearly 80%) participants identified physical (eg, arthritis) or mental disability (eg, dementia) as the primary reason impeding their ease of using WVTs for social connectedness. Both staff and FMs described older adults' difficulties in comprehending the concept of videoconferencing, which often resulted in disengagement during the video call. Despite this, FMs still appreciated the ability to see their loved ones on screen, even if for a brief period. However, this stimulated FMs to seek other easier-to-use WVTs requiring only the FM to start and end a video call.

In addition to physical or cognitive abilities, digital literacy also varied among participants. Staff noted that the pandemic catalyzed WVT use, and as a result, they had to quickly adapt and engage in learning to use the technologies introduced by their workplaces. Families also engaged in mobile learning either individually or with the help of their technologically literate friends or family. These FMs often assumed responsibility for teaching older adults living in LTCHs how to use WVTs. For those older adults who were particularly isolated or for FMs who lacked support, staff members became responsible for teaching, setting up, or troubleshooting the WVTs for them. One staff member shared a story about teaching a husband outside the LTCH how to download and set up Skype so that he could speak to his isolated wife in the LTCH during the pandemic. Some reported that the assessment for the family and older adult's capacity to use technology and planning to support the ease of use would usually take place during the resident admission into LTCH (2 staff), although this was not always the case. Findings also suggest that some families were unaware they could set up video calls upon admission (3 family members).

Surprisingly, only 1 FM explicitly received special training on accessibility features embedded into the device through their workplace to enhance its ease of use for people with varied cognitive and physical abilities. Moreover, only a few (3 FMs and 1 staff) were aware of the accessibility features and how to enable them for easier device use.

Impact on the Workload

The ease of WVT use impacted the workload among staff within LTCHs. Setting up and supporting older adults with videoconferencing was seen as an additional task to do and required coordination between more than 1 health care team, which led to some resistance to use WVTs among staff. One staff member deployed to assist residents with setting up video calls shared:

> *I wouldn't get the residents ready myself; I would ask a personal support worker to get the resident ready. A lot of times I would go to the floor and some of the residents would still be in bed, so I'd be like: "Someone needs to get this person ready for me because it's out of my scope.* [S05]

Another frontline staff member shared that not all staff were willing to facilitate the video calls*:*

> *There's one resident who has her own tablet, who will ask us: "Can you call my daughter?" And we will go and do it for her. Now, when I say we, it's mostly me and one other person. A lot of people don't want to stop and facilitate that because a lot of times there's troubleshooting with a tablet. And people aren't always comfortable doing that kind of thing. Or they don't feel like it's their job to do.* [S09]

Interestingly, staff reticence to assist with web-based videoconferencing technologies use was received with understanding among family and older adults (1 older adult and 1 FM) with some noting that staff already had many work demands and were too overworked to be helping them with videoconferencing. However, 1 FM also added that contextualizing the reason for a video call (eg, social connection) could overcome the staff's resistance to help with setting it up and staying with the person for the duration of a video call if needed:

> *[…] if you had a palliative resident in the middle of the night that wanted to say last good-byes to somebody, wouldn't it be wonderful to be able to connect them virtually with somebody that couldn't be there. I think if it were put in the context like that, it could be woven into some of the other training that you give your nursing staff.* [FM21]

The perceived ease of use of WVTs in this study was influenced by a range of factors, from choosing the ergonomically suitable device to calibrating it based on unique needs and integrating its use into a care plan given the realities of staff workload.

Discussion

Principal Findings

This qualitative study examined perceptions of usefulness and ease of using web-based videoconferencing hardware and software to facilitate social connectedness between older adults living in LTCHs and FMs. In-depth interviews conducted with 3 participant groups—older adults living in LTCHs, FMs, and LTCH staff—suggest that many older adults and FMs benefited from WVTs, and families were creative in finding workable solutions to facilitate older adults' use of technology despite their potential physical and cognitive limitations. Findings informed by the TAM model were collated in 3 overarching themes: actual system use, perceived usefulness, and perceived ease of use to help inform understanding of WVT use in LTCHs. Key findings in this study include introduction of the WVTs during the COVID-19 pandemic positively impacted emotional

XSL•FO
RenderX

well-being of socially isolated older adults in LTCHs and their FMs when in-person visitations were restricted; design and ergonomics greatly influenced the use of WVTs, and staff along with FMs were instrumental in finding ways to make WVTs useful and easy to use, especially for older adults with cognitive or physical impairments; and there was a notable decline in WVT use in LTCHs for social connectedness post COVID-19 pandemic despite heavy reliance on WVT programs to maintain a sense of connectedness during the pandemic.

Actual System Use

Besides commonly used WVTs like iPads or Zoom platform, FMs and staff participants in this study who provided care to the older adults living with dementia used several devices such as Portal, ViewClix, Alexa Echo Show, and Signal, which are understudied in the literature. For instance, a literature search yielded only 1 study exploring Alexa Echo Show to maintain social connection among older adults without impaired cognitive abilities during the COVID-19 pandemic [62]. Smartphones, iPads, or laptop devices, as well as FaceTime, Skype, or Zoom digital software are the most commonly used WVTs reported in the literature to facilitate social engagement and residents' emotional well-being [25,29,36,41,63-66]. These hardware and software are useful for many people; however, they might not have embedded accessibility features required for people with special needs, which was noted in this study. In addition, WVT users may require additional assistance, either provided by staff (which may not be realistic to integrate in the current workflow) or due to the variable availability of informal support by friends or family.

Participant experiences highlight the limited number of formal roles (eg, recreational activity specialists), resources (eg, tailored technologies and their maintenance), and programs (eg, digital literacy workshops) to support ongoing WVT use. The lack of WVT use for social connectedness, particularly post pandemic, signals an emphasis on in-person activities and, concomitantly, ongoing staff shortages, which are also reported in other research [67]. The sustained use of WVTs for social connectedness in this study was found among those who were most familiar and comfortable with technology and who were separated by great geographical distances, a finding corroborating other research [66]. However, there were FMs of older adults in this study who were unaware of the ongoing availability of WVTs despite expressed interest in using this modality. This indicates a growing preference for multiple modes of fostering social connection with those residing in LTCHs.

Perceived Usefulness

Study findings demonstrated that LTCH staff valued using WVTs with families as a means to enhance social presence and for its positive effects on older adults' well-being, even if they had advanced dementia and were unable to fully comprehend how videoconferencing functioned, which is echoed in other research [36,63,67,68]. Participants in this study and other research [69] reported increased usefulness of WVTs for social connectedness facilitated by LTCH staff or family members, as it allowed older adults to remain remotely connected with their families despite restrictions on in-person visits. Although some of the older adults with more pervasive cognitive shortcomings found it challenging to engage in conversation, videoconferencing experiences still elicited positive reactions and emotions, in accord with findings reported in the literature [36,63,67]. Despite the potential challenges of WVT use, they were perceived as a valuable tool to support well-being, foster engagement between older adults and their family, and enhance patient-centered care [67].

Notable was the lack of clarity voiced by some participants about the availability of and ability to use WVTs, particularly once the acuity of the pandemic had subsided. Although WVT use declined post pandemic in LTCHs, older adults and their FMs described it as a useful and desired service for ongoing use. To achieve optimum quality of life while residing in LTCHs, older adults and their FMs expect greater opportunities for social interactions and higher quality and quantity of family engagement [70], which can be addressed by using WVTs. For example, participants in this study shared that videoconferencing allowed them to stay connected to their life and maintain habits established before moving to LTCHs (eg, virtually visiting the garden they used to walk through and interacting with their pet). This propensity of WVTs to provide access to other contexts may foster a sense of aging in place [71] among older adults who are living in LTCHs.

In addition to supporting social well-being, WVTs may also have an important clinical role, in the form of telemedicine, as these modalities reduce time needed to travel, allow timely access to specialized health care personnel [37] and are a cost-effective solution that could alleviate the need for emergent visits [72]. The added examples of usefulness make it worthwhile not only to sustain but also expand WVT service [73].

Perceived Ease of Use

Participants in this study independently researched and shared their knowledge of Portal, ViewClix, or Alexa Echo Show. These WVTs were perceived as easier to use for people with cognitive impairment (eg, dementia) than iPads. Although iPads have been commonly leveraged for their convenience and wide societal acceptance, these types of mobile devices often presented challenges for those older adults who had cognitive or physical disabilities or who lacked experience in using WVTs. In line with this finding, higher tablet or iPad use is predicted by factors such as younger age, higher cognitive functioning, and absence of hearing impairment [66]. The use of devices such as Portal, ViewClix, and Alexa Echo Show highlighted in this study warrants further exploration. These devices could be well-situated to address some of the identified challenges of WVT use among older adult populations and in those with increasing health complexity, such as is often found within LTCH settings [74]. This is especially relevant because a lack of social contact was identified as a risk factor for developing dementia, and preventative action is best initiated early [75].

Findings in this study also suggest that staff members noted digital literacy challenges among some FMs as well as older adults living in LTCH, which is echoed across other studies [63,67]. Low digital literacy among older adults may amplify social isolation by excluding these individuals from participating in social processes or spaces [76,77], many of which have

XSL•FO
RenderX

shifted their operation to digital spaces in recent years. Moreover, since in many instances the FMs were pivotal for initiating the video calls [36], low digital literacy among them resulted in additional responsibility being assumed by LTCH staff who were required to provide education and manual support [36,67]. These findings highlight the need for broad approaches to foster widespread WVT uses among older adults that consider cost, digital literacy, individual capabilities, usability of these tools, and training and use requirements.

Although WVTs are challenging to use for some older adults [64], looking to the future, more people will likely expect to use and be supported in using WVTs in LTCHs as younger generations of society use these devices regularly and consistently within their daily lives. The importance of digital literacy training and accessibility features to facilitate independent use of WVTs by older adults is documented in the literature [78]. This study also identified limited awareness about, and knowledge of, accessibility features embedded in the WVTs by participants which, in turn, could enhance the ease of their use. Although previous works have identified low digital literacy among older adults [64] and a lack of training available within LTCHs to guide their use of WVTs [36,66], there remains a gap in research regarding implementing digital literacy training programs with older adults in LTCHs and their families. In fact, research suggests that in some cases, FMs have been the ones to take initiative and provide the technology necessary for WVTs within LTCHs [79]. Moving forward, additional funding and education to increase technology availability, enhance digital literacy, and increase staffing support roles within LTCH are warranted.

Staff participants in this study and in others [36,63,67] expressed concern regarding their workload and challenges to integrate videoconferencing with their other roles and responsibilities. Interestingly, a few FM participants in this study were accepting of limited opportunities to connect with their older adult member using WVTs due to staffing shortfalls. It is plausible that widespread awareness of the workload and employment challenges common within LTCHs across Canada contributed to their acceptance [80]. This finding demonstrates families' awareness and compassion for those employed within LTCHs, but it also highlights the ongoing paucity of resources directed toward supporting the psychosocial well-being of older adults within LTCHs. In addition, it highlights the lack of policy to support widespread use of WVTs in LTCHs. For instance, burdened staff being too busy to provide assistance with WVT use is documented in the literature [66,79]. Institutional supports are paramount to sustain the WVT service for social connectedness and include additional staffing and redefining roles and responsibilities among LTCH staff to foster digital literacy among older adults in LTCHs or, alternatively, to assist older adults and their families in using WVTs [81]. Addressing these factors simultaneously may facilitate smoother integration of this service into LTCHs while limiting the burden on older adults, their families, and staff.

Implications

Findings from this study highlight the importance of a breadth and depth of approaches to effectively implement and sustain the integration of WVT programs for social connectedness within LTCHs. Government and the private sectors must allocate funding to allow for technology procurement and infrastructure improvements to support wide-scale WVT use within LTCHs. This could be achieved by targeted funding grants or through capital funding initiatives. To maintain WVT use over time, policies and funding to guide its use are also required. Recognition that personnel is required for successful long-term use is paramount if older adults and families are going to benefit. There could be opportunities for expanded roles or even volunteer positions to help older adults use WVTs. In terms of choosing the WVTs, guidelines that ensure accessibility and user-centeredness for individuals with cognitive or physical impairment are required to ensure equitable use of WVTs. In anticipation of the increasingly digitalized health care and potential future increase in using WVTs by individuals in our society, additional roles for staff should be created to be able to support, sustain, and expand WVT programs for social connectedness and health care in LCTHs.

Interdisciplinary care teams in LTCHs can leverage WVTs in their daily routines or activities to improve older adults' physical and psychosocial well-being and create opportunities for more family engagement. Care teams should create opportunities for older adults and their families to engage in digital literacy workshops to optimize benefits from using WVTs by a greater number of older adults and their families. Staff members should also engage in digital literacy training with a particular focus on troubleshooting WVTs and innovating ways they can incorporate WVTs into their daily activities to promote a sense of meaningful social connectedness among older adults residing in LTCHs.

This study highlights the need to explore long-term impacts on health and well-being of using WVTs with residents and their families. Future studies should focus on exploration and comparison of WVTs to determine the most appropriate WVTs to promote social connectedness, especially for individuals living with cognitive or physical impairments. In addition, metrics on the impact of using WVTs for older adults' well-being should be collected to determine different aspects of WVTs' usefulness for older adults in LTCHs. Future research studies should also explore or develop sustainable models to enhance digital literacy training for older adults and their families.

Strengths and Limitations

A strength of this study is the robust participant sample representing multiple perspectives and experiences in using WVTs for social connectedness. Although staff participants were all female, this parallels research suggesting that 90% of personal support workers employed in Ontario are female and 75% of care workers across Canada are female [82,83]. In addition, collaborating with 3 LTCH sites for participant recruitment supported collection of a diverse range of experiences across the different settings. This mitigated a risk for biased results that would be imposed by the nature and operations of a single facility.

While efforts were made to recruit a range of older participants living in LTCHs, we recognize that the inclusion criteria of mild

XSL•FO
RenderX

or no cognitive impairment constrained the participation of older adults. Those who had advanced dementia or other severe neurocognitive deficits were not included, which likely represented a notable portion of those residing in LTCHs who live with dementia [84]. Those older adults who had mild deficits or other physical limitations that impacted their ability to participate were offered assistance in setting up the technology so they could still participate. The findings revealed that frontline staff, particularly nurses and personal support workers, were instrumental in facilitating WVT use among older adults and their families, although this responsibility posed potential burdens on staff workload. Future work could address targeted personnel support for WVT use, including the potential for volunteer technology facilitation or expanding frontline provider roles to include assisting older adults to use technology such as WVTs. Experiences of staff in various LTCH facilities may differ in terms of digital literacy training provided to staff or role expectations. Moving forward, it would be helpful to have clear guidelines to inform staff roles in providing technology support, particularly in the case of supporting older adults' well-being, including social connectedness. In addition, this study did not delve into other factors that may contribute to the decline in using WVTs post pandemic, like for instance, the complex psychosocial factors that influence technology adoption.

Conclusions

The experiences of older adults residing in LTCHs, FMs, and staff demonstrate that using WVTs for social connectedness positively impacts older adults and their FMs' emotional and social well-being. However, WVTs service needs to be tailored to the needs of the families, including the choice of the device, digital literacy training, and provision of human resources to support connections. Moving forward, LTCHs should develop formal programs that allow for integration of WVTs service to expand the opportunities for older adults in the LTCHs to connect socially with their families or use WVTs in other ways that create a sense of social connectedness. To achieve this, funding initiatives such as capital improvement funds and clearer policies on the roles of personnel support will be required. Prospective studies should implement WVTs in collaboration with other actors participating in the process of socially connecting people with WVTs, such as technology industry partners, companies allowing people to participate in or attend leisure activities virtually, and public health organizations to explore additional impacts of WVTs on social and clinical well-being of older adults in LTCHs and their families.

Abstract

Background: Loneliness is a growing public health challenge among older adults and is associated with a wide range of adverse health outcomes. The role of eHealth literacy in shaping the relationship between loneliness and quality of life remains unclear.

Objective: This study aimed to examine the contributing role of eHealth literacy in moderating the associations between loneliness and quality of life among older adults.

Methods: A community-based survey was conducted in 2025 among older adults aged 60 years or older living in northwestern China. A total of 2110 participants were included. Multiple linear regression and interaction models were used to assess associations and moderating effects. Sensitivity analyses were conducted by replacing the outcome variable with depressive symptoms and by performing stratified analyses to assess the robustness of the primary interaction findings.

Results: Loneliness showed a consistent negative association with quality of life (β=−0.83, 95% CI −1.18 to −0.49; *P*<.001). Higher overall eHealth literacy was associated with better quality of life (β=0.41, 95% CI 0.35-0.47; *P*<.001). Interaction models indicated that higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life (β=−0.04, 95% CI −0.08 to −0.002; *P*=.04). Sensitivity analyses produced similar results across alternative outcomes and subgroups.

Conclusions: Higher loneliness was related to a poorer quality of life. Higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life. These findings suggest that eHealth literacy may function as a double-edged sword in later life. Future research is needed to clarify the underlying mechanisms and to examine how digital health competencies interact with psychosocial vulnerability in shaping older adults' well-being.

KEYWORDS

loneliness; quality of life; eHealth literacy; health of older adults; China; cross-sectional study

Introduction

Quality of life refers to an overall appraisal, both subjective and objective, based on an individual's physical health, psychological state, social relationships, and living environment [1]. It encompasses both objective resources, such as health and economic conditions, and subjective experiences, including life satisfaction and well-being [2]. With accelerating population aging, the growing burden of chronic diseases and cognitive decline constrains social participation among older adults and increases their risk of reduced quality of life [3,4]. In China, rapid urbanization and changes in family structure are reshaping intergenerational relationships [5], with adult children increasingly living apart from their parents [6]. At the same time, family care and emotional support have weakened, and the proportion of older adults living alone has risen, together compounding the risk of poorer quality of life in later life [7]. Therefore, identifying the psychological and social determinants of quality of life in older adults is essential for designing targeted interventions and shaping effective pathways to healthy aging. In addition to quality of life, depressive symptoms represent a closely related psychological outcome that reflects emotional well-being and mental health status among older adults [8]. Previous studies have shown that loneliness is strongly associated with depressive symptoms and that both constructs capture important but complementary aspects of psychological

XSL•FO
RenderX

vulnerability in later life [9,10]. Given this close conceptual linkage, depressive symptoms can serve as an alternative outcome to examine whether the observed associations are robust across related mental health indicators.

Loneliness is a subjective social emotional state that arises when individuals perceive a gap between the quantity or quality of their actual social relationships and their desired level of connection, leading to feelings of distress and loss [11]. Loneliness is now widely regarded as an important public health concern. A recent global systematic review estimated that the pooled prevalence of loneliness among community-dwelling older adults is about 32%, with substantial variation across regions and settings [12]. In China, survey data indicate that 36.6% of adults aged 60 years or older report some degree of loneliness, with higher levels observed among women, those living alone, individuals in poorer health, and those with lower socioeconomic status [13]. Previous studies have shown that loneliness is an important risk factor for a range of adverse health outcomes, including coronary heart disease and stroke [14], and is associated with a 26% to 50% increase in mortality risk [15,16]. The excess mortality attributable to loneliness is comparable in magnitude to that associated with physical inactivity or smoking [15]. Moreover, loneliness reduces subjective well-being and life satisfaction and further undermines quality of life in later life [17]. These findings highlight the need to treat loneliness as a key psychosocial determinant when examining quality of life in older adults and to clarify its pathways of influence to inform the design of targeted interventions.

eHealth literacy is commonly defined as the combined ability to locate, understand, appraise, and apply health information in internet-based and digital environments in support of health-related decision-making [18,19]. From the theoretical perspective, eHealth literacy may exert a bidirectional moderating influence on the relationship between loneliness and quality of life. According to the stress-buffering model, access to informational and emotional resources can mitigate the adverse impact of psychosocial stressors on health outcomes [20]. Within this framework, higher eHealth literacy could enable older adults experiencing loneliness to obtain trustworthy health information, access online social and community resources, and engage in self-management, thereby attenuating the detrimental effect of loneliness on quality of life. In contrast, frequent and intensive searching for health information online has been linked to heightened health anxiety and cyberchondria. Exposure to large volumes of risk-focused or conflicting information may generate additional stress and confusion [21]. For older adults who are already lonely and emotionally vulnerable, such patterns of information use may be associated with increased concerns about illness and a stronger negative association between loneliness and quality of life.

Therefore, the aims of this study are to (1) investigate the relationship between loneliness, eHealth literacy, and quality of life and (2) further explore the potential moderating role of eHealth literacy between loneliness and quality of life.

Methods

Participants and Procedure

This study was based on a community-based cross-sectional survey conducted among older adults aged 60 years and older in the Lanzhou New Area of Gansu Province, China. Lanzhou New Area is a national-level administrative district that oversees 7 community health service centers and 80 family physician teams. All 7 centers participated in the survey. Each family physician team was required to complete at least 20 household-based interviews. Among more than 30,000 older adults registered in the catchment areas of these centers, approximately 10% were randomly selected, yielding 2486 recruited participants in March 2025.

A standardized data collection procedure was implemented to maintain consistency across centers. Family physicians received centralized training before fieldwork. Questionnaires completed in less than 600 seconds were excluded, removing 290 responses. Another 86 individuals submitted duplicate entries and were therefore excluded. The final analytic sample consisted of 2110 participants..

Measures

Loneliness

Loneliness was assessed using the Three-Item Loneliness Scale [22]. The scale consists of 3 items, each rated on a 3-point response format with “1= hardly ever,” “2= some of the time,” and “3= often.” Scores from the 3 items were summed to generate a total loneliness score ranging from 3 to 9. Higher scores indicate greater perceived loneliness. The internal consistency of the scale was high, with a Cronbach α of 0.872. The full-scale content is provided in Table S1 in Multimedia Appendix 1.

Quality of Life

Quality of life was measured using the brief Older People’s Quality of Life Questionnaire, which includes 13 statements covering core domains of well-being [23]. Participants indicated their level of agreement with each statement using a 5-point response scale ranging from strong disagreement to strong agreement. Item scores were summed to generate a total score ranging from 13 to 65, with higher values reflecting better quality of life. The scale demonstrated excellent internal consistency, with a Cronbach α of 0.975. The full list of items is available in Table S2 in Multimedia Appendix 1.

eHealth Literacy

The eHealth literacy was evaluated using an 8-item instrument [24]. Each item was rated on a 5-point Likert scale ranging from very inconsistent to very consistent. Scores were summed to produce a total ranging from 8 to 40, with higher values indicating stronger eHealth literacy. In this study, the eHealth literacy scale showed excellent internal reliability, with a Cronbach α of 0.980. Following prior studies, the total eHealth literacy score was treated as a continuous variable in the primary analyses [24,25]. In addition, the exploratory analyses were conducted to examine potential heterogeneity across groups of items within the scale. For this purpose, the 8 items of the

XSL•FO
RenderX

eHealth literacy scale were grouped by the authors into 3 sets based on their content, reflecting applying literacy items (items 1‐5), critical literacy items (items 6‐7), and a decision-making literacy item (item 8). These item groupings were defined for exploratory purposes only and do not represent validated subscales of the instrument. Details of the instrument are presented in Table S3 in Multimedia Appendix 1.

Depressive Symptoms

Depressive symptoms were assessed using the 9-item Patient Health Questionnaire. This instrument contains 9 items that capture the frequency of core depressive experiences [26]. Each item is rated on a 4-level scale, ranging from 0 (not at all) to 3 (nearly every day), with response options of 1 (several days) and 2 (more than half of days). Scores were added to create a total ranging from 0 to 27, with higher values reflecting more pronounced depressive symptoms. The internal reliability of the scale was strong, with a Cronbach α of 0.921. Depressive symptoms were included as an alternative outcome variable in sensitivity analyses, replacing quality of life to assess the robustness of the primary interaction findings. Additional details are provided in Table S4 in Multimedia Appendix 1.

Potential Confounders

Demographic and socioeconomic variables controlled for in the regression models included sex (male or female), age in years (60‐69 years, 70‐79 years, or ≥80 years), marital status (single, married, or partnered), education (less than high school or high school or above), employment status (not working or working), self-reported health status (bad, general, or good), chronic diseases (no or yes), smoking (no or yes), and alcohol consumption (no or yes).

Statistical Analysis

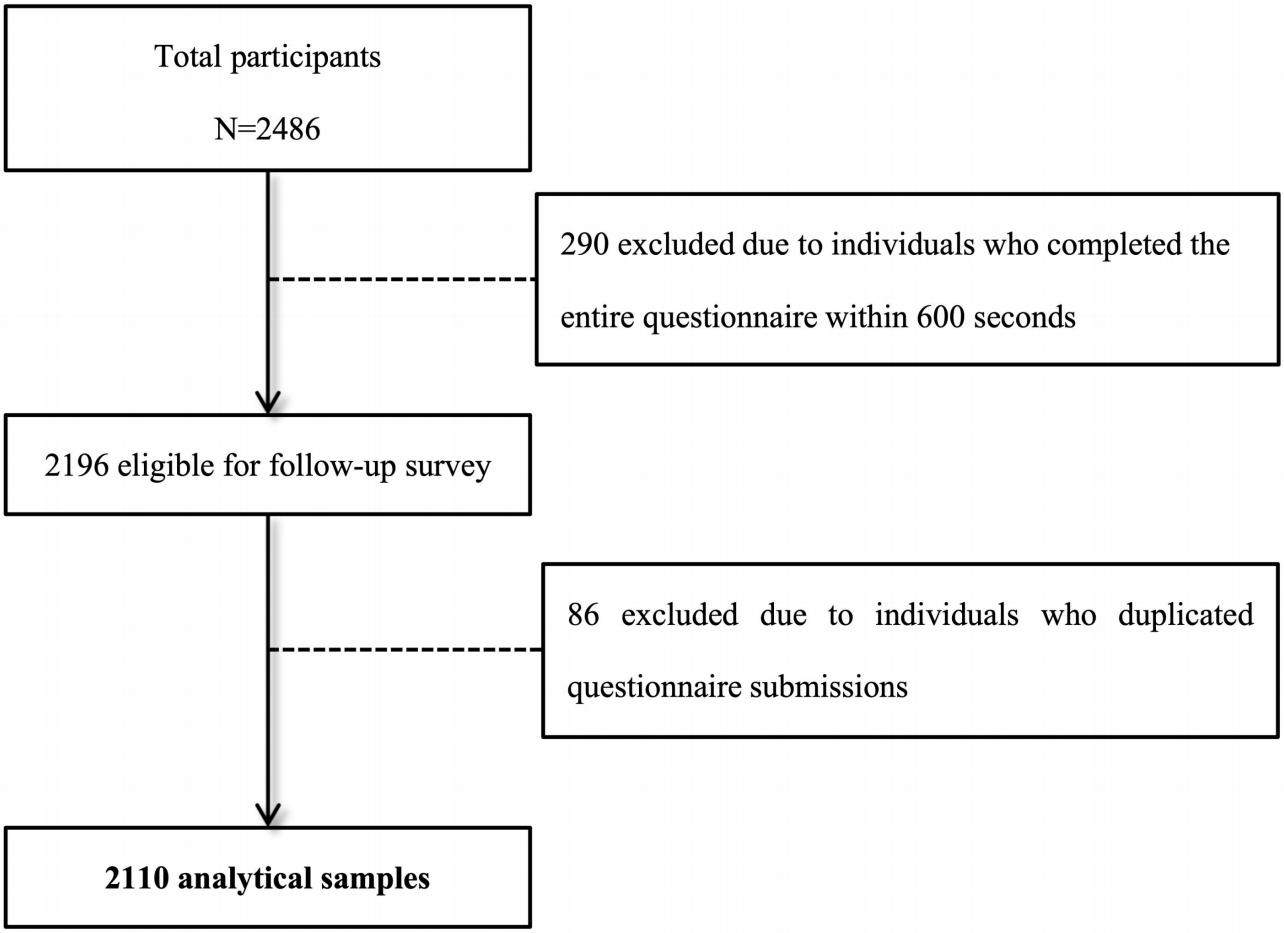
Descriptive analyses were conducted to characterize the study sample. Continuous variables were presented as medians together with IQRs. Categorical variables were summarized using counts (n) and proportions (%).

Multiple linear regression models were fitted to examine the association between loneliness and quality of life. To evaluate the moderating role of eHealth literacy, interaction terms between loneliness and eHealth literacy were introduced. The primary analyses were conducted using the total eHealth literacy score as a continuous variable. Analyses based on item groupings of eHealth literacy were exploratory in nature and are presented in Multimedia Appendix 1. Prior to constructing the interaction terms, continuous variables involved in the interaction analyses were mean-centered to improve interpretability and reduce potential multicollinearity. To facilitate interpretation of the moderation effect, predicted values of quality of life were estimated at +1 or −1 SD of eHealth literacy, and the results were visualized. In addition, simple slope analyses were conducted to estimate the association between loneliness and quality of life at different levels of the continuous moderator. Model linearity assumptions were assessed by visually inspecting residual plots of continuous variables against regression residuals. The plots did not indicate substantial deviations from linearity. All analyses were performed using Stata (version 17.0; StataCorp). A 2-sided *P* value of <.05 was regarded as statistically significant.

To assess the robustness of the primary interaction findings based on the total eHealth literacy score, 2 sets of sensitivity analyses were performed. First, the outcome variable was replaced with depressive symptoms. Interaction models were reestimated with depressive symptoms as the outcome to examine the consistency of the moderating relationship. Second, stratified analyses were carried out with sex as the grouping variable. Robustness was evaluated based on whether the direction or statistical significance of the associations remained consistent after conducting stratified analyses [27].

Ethical Considerations

Formal ethics approval was granted by the institutional review board of Peking University Third Hospital (20250224-01025-0129). Electronic informed consent was obtained from all study participants and assisting family physicians before participation. All data were collected and stored in a deidentified and anonymized form to protect participants' privacy and confidentiality. Access to the data was restricted to authorized members of the research team only. Participation in this study was voluntary, and participants were informed of their right to withdraw at any time without consequences. No financial compensation was provided to participants.



Results

Descriptive Statistical Analysis

Figure 1 presents a flowchart of participant inclusion. Table 1 presents the baseline characteristics of the 2110 participants. Overall, loneliness, quality of life, eHealth literacy, and depressive symptoms were distributed at low to moderate levels. Of the 2110 participants, 1033 (48.9%) were female and 1077 (51.1%) were male. Most participants were aged 60 to 69 years (n=1132, 53.7%), followed by those aged 70 to 79 years (n=798, 37.8%). A large proportion were married or partnered (n=1778, 84.3%) and had education lower than high school (n=1802, 85.4%). The majority were not working (n=1919, 90.9%). Self-reported health was most commonly rated as general (n=1247, 59.1%). Chronic diseases were reported by 1232 (58.4%) participants. Most participants did not smoke (n=1536, 72.8%) and did not consume alcohol (n=1677, 79.5%).

Relationship Between Loneliness, eHealth Literacy, and Quality of Life

Table 2 summarizes the results of the multiple linear regression models. In model 1, loneliness was significantly associated with lower quality of life (β=−0.66, 95% CI −1.03 to −0.29; *P*<.001). After adding eHealth literacy in model 2, this association remained significant and became slightly stronger (β=−0.83, 95% CI −1.18 to −0.49; *P*<.001). eHealth literacy was positively associated with quality of life (β=0.41, 95% CI 0.35-0.47; *P*<.001).

[f]P<.01.

[g]P<.05.

Exploratory analyses based on author-defined item groupings of eHealth literacy were conducted to examine their associations with quality of life. The results showed broadly consistent patterns with the primary analyses based on the total eHealth literacy score. Detailed results are presented in Table S5 in Multimedia Appendix 1.

Results of Multiple Linear Regression With Interaction Terms

Table 3 shows the results of the interaction models. In model 6, the interaction between loneliness and eHealth literacy was significant (β=−0.04, 95% CI −0.08 to −0.002; P=.04), indicating that higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life. The inclusion of eHealth literacy and its interaction with loneliness increased the explained variance in quality of life from 6.58% (model 1, R^2=0.0658) to 15.37% (model 6, R^2=0.1537), indicating improved model explanatory power (ΔR^2=0.0879). When comparing the model with main effects to the interaction model, the incremental contribution of the interaction term was 0.0016 (model 6, R^2=0.1537; model 2, R^2=0.1521; ΔR^2=0.0016), and the interaction effect was statistically significant. Additional exploratory analyses examined interaction effects between loneliness and the author-defined item groupings of eHealth literacy. The patterns were consistent with the primary interaction findings based on the total score. Detailed results are presented in Table S6 in Multimedia Appendix 1.

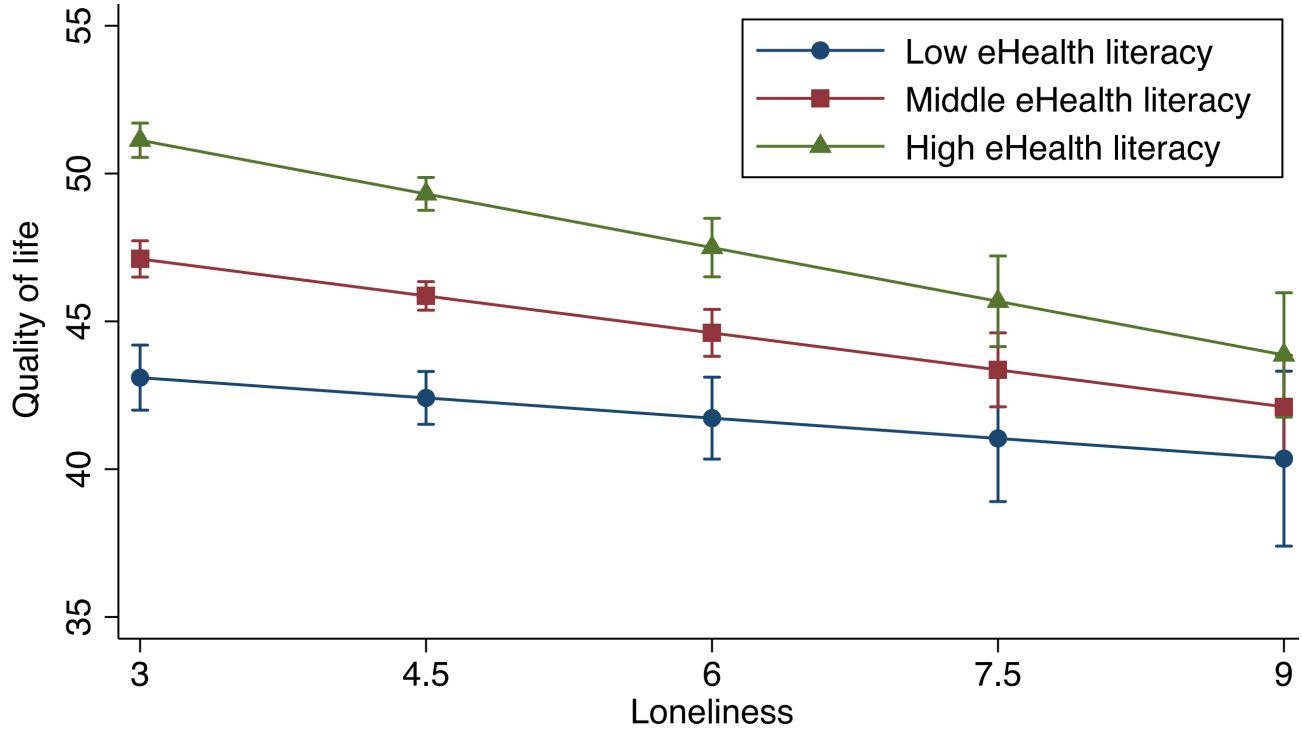
[a]R^2=0.1537.

[b]P<.001.



[c]The continuous variable of eHealth literacy has been mean-centered.

[d]P<.05.

[e]Adjusted for all covariates.

To further interpret the interaction between loneliness and eHealth literacy, predicted values of quality of life were estimated at different levels of the continuous moderator. Figure 2 presents the interaction plot based on mean-centered eHealth literacy, with predicted values shown at low (mean−1 SD), middle, and high (mean+1 SD) levels of eHealth literacy. The results indicate that quality of life declined as loneliness increased across all levels of eHealth literacy. Simple slope analyses showed that the association between loneliness and quality of life was not statistically significant at low levels of eHealth literacy (simple slope=−0.46; P=.13), but became significantly stronger at the middle levels (simple slope=−0.83; P<.001) and high levels of eHealth literacy (simple slope=−1.21; P<.001). These findings suggest that the negative association between loneliness and quality of life becomes more pronounced as eHealth literacy increases.

Figure 2. Moderating effect of eHealth literacy on the relationship between loneliness and quality of life.

Sensitivity Analysis

Table S7 in Multimedia Appendix 1 shows the results of the interaction models when depressive symptoms were used as the outcome. Loneliness remained strongly associated with higher depressive symptoms across all models. The interaction between loneliness and eHealth literacy was significant and positive, suggesting that higher eHealth literacy was associated with a steeper positive association between loneliness and depressive symptoms (model 10). Figure S1 in Multimedia Appendix 1 illustrates the simple slopes of loneliness on depressive symptoms at different levels of the continuous eHealth literacy moderator. Depressive symptoms increased with higher levels of loneliness across all levels of eHealth literacy (low eHealth

XSL•FO
RenderX

literacy, simple slope=1.62; *P*<.001 vs middle eHealth literacy, simple slope=1.84; *P*<.001 vs high eHealth literacy, simple slope=2.06; *P*<.001). The slope was steeper at higher levels of eHealth literacy, indicating that the positive association between loneliness and depressive symptoms became stronger as eHealth literacy increased. These results indicate that the moderating role of eHealth literacy remained stable when the outcome variable was replaced, supporting the robustness of the study findings.

Table S8 in Multimedia Appendix 1 presents the stratified results. In both male and female participants, eHealth literacy continued to show a positive association with quality of life. The interaction between loneliness and eHealth literacy was significant among female participants (β=−0.07, 95% CI −0.13 to −0.01; *P*=.02). Overall, the stratified models showed that the interaction results were consistent with the primary interaction findings based on the total eHealth literacy score, indicating the robustness of the findings.

Discussion

Principal Findings

This study examined loneliness, eHealth literacy, and quality of life among older adults in China and assessed the moderating role of eHealth literacy. Loneliness showed a clear negative association with quality of life. Higher eHealth literacy was positively associated with quality of life. Interaction analyses indicated that higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life among older adults.

This study found a consistent negative association between loneliness and quality of life among older adults. This result aligns with evidence from cohort studies and systematic reviews showing that loneliness is linked to depression, anxiety, physical decline, cardiovascular events, and higher all-cause mortality, as well as sustained reductions in subjective well-being and health-related quality of life [10,15,17,28]. Persistent loneliness may impair psychological and social functioning through pathways involving functional deterioration [29], negative emotional accumulation, and reduced social participation, thereby undermining quality of life. These findings highlight the importance of prioritizing loneliness reduction in healthy aging policies and community interventions aimed at improving quality of life in later life.

We observed a robust positive association between eHealth literacy and quality of life in older adults. Existing evidence indicates that higher eHealth literacy enhances the ability of older adults to obtain and understand online health information [30], supports the use of digital health services, and promotes self-management [31], which can improve both psychological and physical health and ultimately enhance quality of life [32]. In China, where health care resources are unevenly distributed and accessing offline services can be burdensome, older adults with higher eHealth literacy are more likely to secure timely information and support through digital channels, translating digital access advantages into better quality of life [30,33].

Our study also showed that higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life. This pattern differs from prior evidence, particularly from studies conducted during the COVID-19 pandemic among younger or student populations, where higher eHealth literacy was more commonly found to attenuate the negative associations between fear, loneliness, depressive symptoms, and health-related quality of life [34-37]. These findings suggest that eHealth literacy may have dual effects in digital health environments. Higher eHealth literacy may be accompanied by more intensive health information seeking and greater reliance on self-directed health management, which can increase cognitive load and decision burden [18,31]. Under conditions of loneliness and limited emotional support, greater engagement with online health information may translate into increased tendencies toward cyberchondria and psychological strain, thereby strengthening the association between loneliness and reduced quality of life [38,39]. In addition, in the absence of adequate family support or professional guidance, older adults with high eHealth literacy may also need to interpret complex health information on their own, which can intensify confusion, stress, and uncertainty and create a cumulative negative effect between loneliness and digital information exposure [40]. Furthermore, the cross-sectional design precludes conclusions regarding temporal ordering. It is possible that older adults with poorer well-being or heightened health concerns are more motivated to engage with online health information and to develop or report higher eHealth literacy, while loneliness simultaneously contributes to lower quality of life. This possibility highlights the need for longitudinal and experimental research to clarify directionality and underlying mechanisms. These findings highlight the need to further investigate the context-dependent functions of eHealth literacy and to examine potential mediating mechanisms, including information overload, health anxiety, cyberchondria, and decision burden, through longitudinal and experimental designs that can clarify temporal ordering and causal pathways. Additionally, strategies aimed at enhancing digital competence among older adults may require complementary forms of structured support, such as assistance in interpreting complex online health information and facilitated linkage to trusted community or primary care resources, particularly for individuals experiencing social vulnerability.

Strengths

This study has several strengths. It draws on a large community-based sample of older adults from multiple health service centers, providing robust evidence from a population that is often underrepresented in digital health research. The study simultaneously examined loneliness, eHealth literacy, and quality of life, allowing for a nuanced understanding of how digital competencies relate to quality of life in later life. The use of validated instruments and rigorous quality control procedures strengthened the reliability of the measures. In addition, the inclusion of interaction models and sensitivity analyses enhanced the robustness of the findings. By identifying a pattern in which higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life, this study provides new insights into the complex role

XSL•FO
RenderX

of eHealth literacy and contributes to the understanding of digital vulnerability among older adults.

Limitations

This study has several limitations. First, the cross-sectional design precludes establishing temporal ordering. Future studies would benefit from longitudinal designs to clarify how loneliness and eHealth literacy interact over time and to identify potential bidirectional pathways. Second, all variables were measured through self-report, which may introduce reporting bias. Future research could incorporate clinical indicators, digital trace data, or performance-based assessments to provide more objective measures of health status and online information use. Third, the sample was drawn from one region in northwestern China, and findings may not generalize to areas with different digital access or social support structures, underscoring the value of multisite or nationally representative studies.

Conclusions

This study found that loneliness was consistently associated with lower quality of life among older adults and that higher eHealth literacy was associated with a steeper negative association between loneliness and quality of life. These results suggest that eHealth literacy functions as a dual-edged resource in later life. Although higher literacy is linked to better quality of life overall, it may intensify the challenges faced by lonely older adults when navigating complex or risk-oriented online health information. Given the cross-sectional and observational nature of the study, these interpretations should be considered exploratory. Future research is needed to examine the underlying psychological mechanisms, including potential roles of health anxiety, information overload, or emotional regulation processes, and to determine whether complementary support strategies could mitigate unintended negative consequences in digitally engaged but socially vulnerable populations.

Abstract

Background: Many clinically relevant aspects of health are expressed through behavior, affect, and interaction, and therefore rely on observation rather than instrumental measurement; yet such information is often documented infrequently in routine care. Dementia, and particularly behavioral and psychological symptoms of dementia (BPSD), is a relevant case because symptoms fluctuate across time and context. Little is known about how structured daily symptom assessment can be integrated into routine dementia care practice.

Objective: This pilot study aimed to investigate whether structured daily observation of BPSD, supported by digital documentation, can be incorporated into everyday residential dementia care.

Methods: A convergent mixed methods design was applied across 4 nursing home units in southern Sweden. Feasibility was operationalized through 4 focus areas (implementation, practicality, acceptability, and integration), with adherence to the registration routine as the primary feasibility outcome. Quantitative data comprised structured registrations collected daily by care staff over 90 days for 8 residents with BPSD, analyzed descriptively, and interpreted using selected NASSS (nonadoption, abandonment, scale-up, spread, and sustainability) framework domains to contextualize variation in symptom patterns, adherence, and registration practices. Semistructured dyadic interviews were analyzed using deductive content analysis guided by the same domains, with integration occurring at the analytical and interpretive stages.

Results: A total of 21,993 item-level registrations were completed: 19,123 NPI-NH (Neuropsychiatric Inventory – Nursing Home version) symptom ratings, recorded across 1623 shift registrations (1 per resident per shift), and 2870 individually selected variables. Overall adherence to the registration routine averaged 75% across shifts but varied considerably between residents (range 33% - 90%) and between staff members. Mean time per shift registration decreased from 77.1 seconds in the initial 30-day period to 46.2 seconds in the final 30-day period (P=.008). Symptom prevalence varied widely across NPI domains (7.5% to 38.1% of observation days), and daily symptom counts varied both between and within residents. The routine was experienced as technically straightforward and easy to incorporate into daily work. At the same time, challenges emerged, including time constraints, inconsistent participation, varying levels of interpretive confidence, and difficulties distinguishing among overlapping symptoms. Organizational routines and team stability were central to sustaining staff engagement.

Conclusions: The high number of completed registrations indicates that daily observations can be integrated into daily dementia care. The participants perceived it as meaningful and useful. Feasibility was primarily influenced by organizational and interpretive factors rather than technical constraints. Further research should explore strategies to support shared routines and sustain engagement over time.

Introduction

Care Under Pressure and the Promise of Digitalization

Health care systems in many countries, including Sweden, are under pressure from demographic change: an increasing number of older adults with chronic conditions and complex care needs are met by limited staff and resources [1-4]. At the same time, care is expected to be evidence-based and person-centered [5,6], a standard that is difficult to meet in everyday practice characterized by high workload, time pressure, and gaps in clinical information sharing [7,8]. Digitalization is often proposed as one means to address this gap, through documentation, data collection, and information sharing that can strengthen the informational basis for clinical decision-making and enable more detailed, frequent data on patients' health status [9-11].

Digitalization has expanded the possibility of collecting high-frequency health data that capture patterns and temporal dynamics often missed by episodic assessment and documentation. In several areas of medicine, increasing the frequency of data collection has yielded more detailed insight into health over time, for example, through continuous glucose monitoring in diabetes care [12] and data-intensive cancer diagnostics [13,14]. These advances, however, rely on data generated by sensors or imaging. Many clinically important phenomena, including behavioral and psychological symptoms of dementia (BPSD), are instead captured through staff observation and subjective interpretation, where structured, frequent data are far less available and data-driven methods correspondingly less established. Realizing comparable benefits in such domains therefore depends first on whether observational data can be captured systematically and frequently enough in everyday practice.

The Documentation Gap in Observational Care

In such observation-based aspects of care, professional judgment remains central to detection and interpretation [15], and both the assessment routine itself and the data it generates can provide important insight into a person's situation, needs, and well-being [16]. However, these assessments are typically documented in episodic, narrative formats that lack the standardization and temporal resolution needed to detect gradual or subtle changes over time [17]. This stands in contrast to instrumental measurements, where increasingly continuous and automated data collection enables fine-grained tracking of change [18].

This documentation gap is particularly evident in long-term care settings, where individuals rely on staff to observe and interpret their needs. Through continuous interaction, staff accumulate substantial tacit knowledge about behavioral patterns, functional fluctuations, and early signs of change [19]. While such knowledge is often clinically meaningful, it is unevenly documented and therefore vulnerable to variation [20]. Differences in staff experience and training [21], challenges related to documenting unstructured information [22], and technical constraints in digital systems [23] may all contribute to variation in how observations are recorded. Consequently, clinically relevant information may remain undocumented or circulate primarily through informal communication. Structured, high-frequency observational routines may offer one way to stabilize and render this tacit knowledge more visible and actionable. In dementia care, key data types that benefit from systematic capture include the presence and severity of behavioral and psychological symptoms, daily functional fluctuations, and context cues such as activity, sleep, and interpersonal interactions. Documenting these systematically rather than informally is a prerequisite for using them in care planning.

BPSD as a Case of Rapid Symptom Fluctuation

Dementia, and especially BPSD, provides a particularly relevant case for examining this documentation gap, as symptoms fluctuate episodically across time, environments, and internal states. Dementia is a progressive neurocognitive condition affecting a large and growing proportion of older adults worldwide [24,25], and up to 90% of people living with dementia experience BPSD over the course of the condition [26,27]. Symptoms include agitation, anxiety, hallucinations, delusions, irritability, apathy, and sleep disturbances. BPSD substantially affects quality of life, caregiver burden, rates of institutionalization, and the need for tailored interventions [28,29].

Moreover, several BPSD symptoms share overlapping behavioral expressions, making clinical differentiation challenging even for experienced staff [30]. This interpretive complexity adds a further dimension to the documentation challenge, as structured assessment depends not only on frequency of observation but also on the clarity with which symptoms can be distinguished and categorized.

Because BPSD emerges from dynamic interactions among neurocognitive decline, personal needs, and environmental context, it requires close and repeated observation. Yet current assessment practices rely largely on periodic evaluations, while day-to-day fluctuations are often documented informally or recalled from memory [31]. In Sweden, the national BPSD Registry provides a structured framework for assessment, but registrations typically occur at intervals of 6 months or more [32]. This structural mismatch between rapidly fluctuating symptoms and episodic assessment systems [33] may leave clinically meaningful variation undetected, limiting opportunities for timely and person-centered intervention.

One possible way to capture this variation is through structured high-frequency observational routines carried out as part of everyday care practice. This raises interrelated questions: whether such structured observation is feasible to perform at all and whether it can be integrated as a routine practice in residential dementia care. The latter is shaped by interrelated technical, interpretive, and organizational conditions. Before larger-scale adoption can be considered, it is therefore necessary to examine whether structured daily observational routines are feasible under real-world conditions [34].

Objective

The overall aim of this pilot study was to investigate whether structured daily observation of BPSD, supported by digital documentation, can be incorporated into everyday residential dementia care. Two research questions were addressed: (RQ1)

XSL•FO
RenderX

What is the feasibility of integrating structured daily observations into residential dementia care? (RQ2) What are the day-to-day and between-resident variations in BPSD registrations? Feasibility was examined with adherence to the registration routine as the primary feasibility outcome, and practicality, acceptability, and integration into existing workflows were examined descriptively.

Methods

Study Design

A convergent mixed methods design was used to examine whether structured daily observation of BPSD, supported by digital documentation, can be incorporated into everyday dementia care. Quantitative and qualitative data were collected concurrently, analyzed separately, and subsequently brought together as part of a structured data integration process, in accordance with established principles for convergent mixed methods research [35].

A convergent design was chosen because the 2 strands addressed the same research question (the feasibility of integrating structured daily observational routines into care) from complementary perspectives, with neither strand subordinate to the other. The quantitative data on adherence, registration patterns, and shift-registration time describe what was accomplished; the qualitative data on staff experiences describe how and under what conditions. A sequential design was not appropriate because neither strand needed to inform the other prospectively, and an embedded design was not appropriate because neither was secondary. Concurrent data collection during the same 90-day study window further supported a convergent approach.

Feasibility was conceptualized using the focus areas described by Bowen et al [36]; four areas were targeted in this pilot: implementation, practicality, acceptability, and integration. The primary feasibility outcome was adherence to the registration routine, operationalized as the proportion of expected item-level registrations completed. The remaining 3 dimensions were explored descriptively without prespecified thresholds. The other 4 Bowen focus areas (demand, adaptation, expansion, and limited-efficacy testing) were considered beyond the scope of this pilot.

In this study, two related but distinct concepts are used in their established implementation-science sense: *implementation* refers to the process of introducing the routine into care (operationalized in this study through adherence, the primary feasibility outcome); *integration* refers to the extent to which the routine fits within existing workflows.

Ethical Considerations

This study was approved by the Swedish Ethical Review Authority (Dnr 2022-04509-01) under two specific conditions reflecting the cognitive vulnerability of the resident population. First, because residents could not reasonably be expected to assimilate written study information themselves, written information was directed to a next of kin, legal guardian, or trustee, who provided consent on the resident's behalf and was instructed to consult the resident and convey the resident's opportunity to object. Because residents could not reliably provide active assent, the procedure relied on this proxy consent together with the resident's ongoing opportunity to object, a nonobjection rather than an active-assent model. Second, the structured daily observations imposed no incremental procedural burden: registrations were integrated into the documentation that care staff would otherwise perform informally during routine care, requiring no additional interaction with the resident. To minimize the handling of personal data, signed consent forms were collected and stored locally by participating unit managers and were never transferred to the research team; the team verified that consent had been completed before each resident was included.

Health care professionals were informed of the study by their unit managers but registered their interest in interview participation directly with the research team via an online form, after which a subset were randomly approached; oral informed consent was obtained prior to each interview. Use of the Daily-BPSD (Jönköping University) application required personal staff login to preserve accountability, in line with standard clinical documentation practice; upon export to the research dataset, staff identifiers were replaced with study codes (eg, "Staff Participant 3"), and the anonymized registration data were stored on secure servers at Jönköping University. Audio recordings and verbatim transcripts of interviews were stored on secure university servers, with the key linking interview codes to identifiable information held separately at Jönköping University. The processing of personal data rested on a public-interest legal basis under the EU General Data Protection Regulation, together with the study's ethical approval.

Settings and Participants

The study was conducted in dementia-specific residential care units within municipal long-term care facilities in southern Sweden. The 4 participating units were located in 2 municipalities and distributed across both urban and smaller community settings, with all 4 operated by their respective municipalities. According to Swedish national guidelines for dementia care, such units are designed to provide round-the-clock care for persons with dementia who require extensive support in daily activities and continuous supervision. Care is typically delivered by assistant nurses, with registered nurses available on a scheduled basis. Staff typically worked in rotating shifts, with day shifts (approximately 7 AM to 3 PM), evening shifts (approximately 3 PM to 9 PM), and night shifts (approximately 9 PM to 7 AM). Dementia-specific units are commonly organized into small-scale living environments, or wards, intended to support person-centered care [37]. Although a unit may comprise several wards, the study residents in each unit belonged to a single ward with a capacity of 8 - 10 residents.

Residents were eligible if they lived in a designated dementia unit and had a medically confirmed diagnosis of dementia. No restrictions were applied regarding age or gender. All included residents exhibited BPSD, although no criteria were applied regarding specific symptoms or severity. Because many residents had significant cognitive impairment that limited their

XSL•FO
RenderX

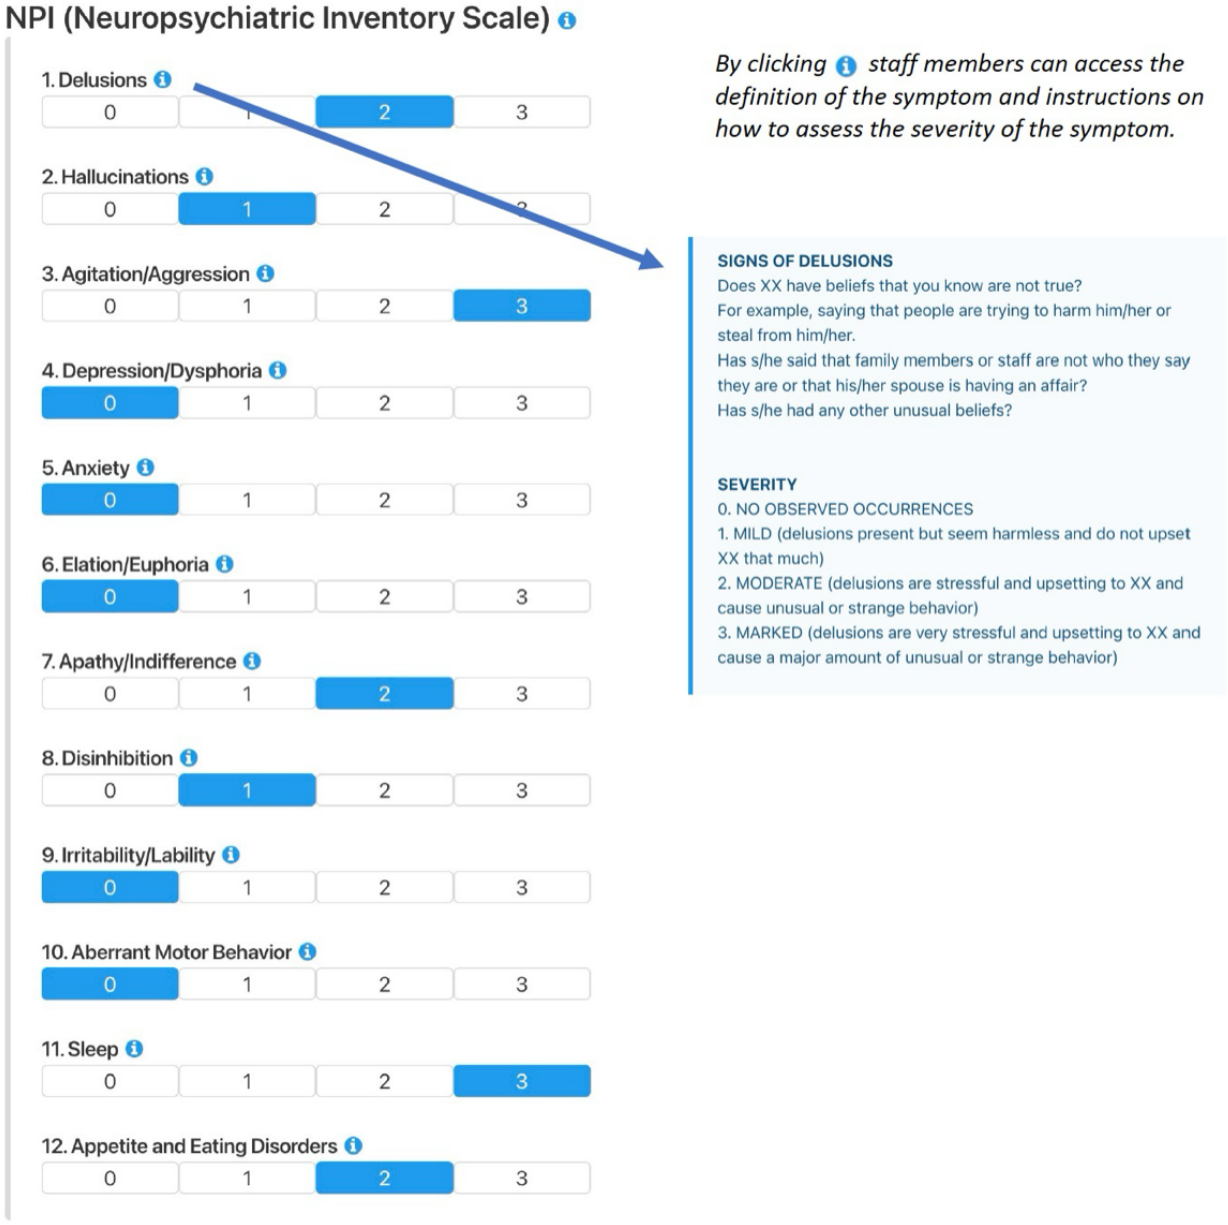
ability to provide informed consent, written proxy consent was obtained from legal representatives or next of kin.

All regular care staff working on the participating units were expected to contribute to the daily observational registrations during the study period as part of their regular work routines. Staff were eligible for qualitative interviews if they had been actively involved in the daily care of included residents.

Unit managers facilitated recruitment by informing staff about the study and coordinating contact with residents' legal representatives or next of kin to obtain written proxy consent. Recruitment followed a convenience sampling approach appropriate for feasibility-oriented research. The sample of 8 residents reflected the practical capacity of the participating units and the research team to support intensive daily observation over the 90-day pilot. Residents were included from all 4 participating units so that the pilot captured daily documentation practices across each care context. Participation in the qualitative component was voluntary, and 10 assistant nurses consented to participate in interviews.

Quantitative Data Collection

The Daily-BPSD Tool



Daily-BPSD is a web-based application designed to support structured daily observation of BPSD as part of everyday care routines. The tool enables staff to register symptom severity up to 3 times per day using smartphones, tablets, or computers.

The interface is based on the 12 domains of the Neuropsychiatric Inventory (NPI) [38], with domain definitions aligned with the Neuropsychiatric Inventory – Nursing Home version (NPI-NH) [39]. Each domain includes a 0 - 3 severity scale, supported by clickable definitions and examples, to promote consistent interpretation among staff (see Figure 1). In addition to the predefined NPI domains, the tool allows optional individualized variables to capture specific care needs or context-sensitive interventions.

Daily-BPSD automatically generates graphical summaries of symptom trends over time directly within the application as new observations are registered, supporting reflection and team communication. The tool was developed in collaboration with care staff and relatives and iteratively adapted to fit existing care workflows, informed by previous findings [31].

XSL•FO
RenderX

Figure 1. Staff interface for registering Neuropsychiatric Inventory (NPI) symptom severity in Daily-BPSD, including clickable definitions and standardized rating guidance. Screenshot from the Daily-BPSD website (2025 Jönköping University, Daily-BPSD project; reproduced with permission).

Quantitative Data Description

Prior to the study period, staff members in participating units received a 2-hour introduction to the Daily-BPSD application, conducted by members of the research team. The introduction covered the rationale for daily symptom registration, navigation of the registration interface, interpretation of NPI severity definitions via the in-app information texts (see Figure 1), and account login.

Using this tool, structured daily observations were recorded for 8 residents over a 90-day period. The system automatically time-stamped each entry, allowing analysis of adherence patterns and temporal distribution of observations. Data were exported in anonymized form and contained no personal identifiers beyond each resident's study code. The quantitative dataset therefore captured both the volume and distribution of observational activity as well as symptom patterns across the study period.

Throughout this study, a *registration* (or *item-level registration*) refers to a single severity rating recorded for one item (either an NPI-NH symptom domain or an individually selected variable) for one resident at one shift; reported registration totals therefore reflect the number of item-level rating events. A *shift registration* refers to one completed NPI form for one resident at one shift (up to 3 per resident per day, one per shift); the 19,123 NPI item-level registrations were recorded across 1623 completed shift registrations. The 2870 individually selected variable registrations are item-level events not tied to a shift form. Registration time is reported per shift registration, not per item-level registration.

XSL•FO
RenderX

Qualitative Data Collection

Qualitative data were collected through semistructured dyadic interviews with 10 assistant nurses conducted in 5 pairs. One pair was recruited from each of the 4 participating units, with one unit contributing an additional pair to include night shift staff. Dyadic interviews were used to encourage interaction between participants and to generate richer accounts of shared experiences within their common care context, allowing participants to validate, contrast, and elaborate on each other's accounts in ways that solo interviews typically do not [40,41]. Participants were eligible if they were regular staff members working on the participating units during the quantitative data collection period and had used the Daily-BPSD tool for daily symptom observation. These 10 assistant nurses were drawn from the care staff who performed the daily observations and contributed to the study by sharing their experiences in the interviews analyzed below. The semistructured interview guide used during the interviews is provided in Multimedia Appendix 1.

The interviews were held at the end of the observation period to allow participants to reflect on their experiences throughout the monitoring period. The interview guide covered topics related to daily observational routines, how behavioral and psychological symptoms were interpreted, factors affecting symptom judgment, and contextual conditions influencing feasibility, such as workload, team coordination, and local documentation practices. Questions were informed by earlier developmental work [31] and by selected domains of the NASSS (nonadoption, abandonment, scale-up, spread, and sustainability) framework [42], which also guided the subsequent deductive analysis.

All interviews were conducted by members of the research team in the participating residential care units, audio recorded with consent, transcribed verbatim, and anonymized. Field notes were taken to capture situational aspects relevant for later analysis.

Data Analysis

Analytic Framework

Whereas the feasibility outcomes specified above identified what was assessed in this study, the NASSS framework [42] was applied to interpret why feasibility-relevant patterns emerged. NASSS is widely used to examine the implementation, scale-up, and sustainability of health technologies in complex care systems [43-45]. Based on the study's aim and familiarization with the empirical material, 5 NASSS domains were identified as analytically relevant: condition, technology, value proposition, adopters, and organization. To facilitate integration of qualitative findings with the quantitative data on adherence and symptom patterns, qualitative findings are reported under the NASSS domains used in the deductive analysis rather than independent categories.

The *organization* domain was included to account for unit-level variation in workflow, leadership support, staffing patterns, and local routines, all of which shaped the feasibility of integrating structured daily observational practices into everyday care.

The *condition* domain was particularly relevant because BPSD are fluctuating, context-dependent, and often unpredictable qualities that fundamentally shape what structured daily observational practices must capture.

The *technology* domain was used to examine the work required to conduct structured daily observations, including usability aspects of the digital interface and how the routine aligned with existing documentation practices.

The *value proposition* domain captured staff perceptions of the usefulness of frequent documentation for reflection, communication, care planning, and understanding residents' needs.

The *adopters* domain addressed how staff members' interpretive skills, motivation, confidence, and perceived workload influenced both the consistency with which observations were conducted and the extent to which the resulting data were used in practice.

These domains informed the deductive coding matrix in the qualitative analysis and provided a structured lens for integrating quantitative and qualitative findings across the convergent mixed methods design. While the NASSS domains provided the primary analytical structure, the analysis remained open to relevant insights not fully captured by the predefined domains. The remaining NASSS domains (wider system and embedding and adaptation over time) were not included because they address system-level influences and long-term adaptation processes that were beyond the scope of this study.

Quantitative Analysis

Quantitative data were analyzed descriptively to examine adherence to daily observational routines, the frequency and distribution of documented symptoms, and temporal variation across the observation period. For each resident, the total number of item-level registrations, the proportion of days with completed entries, and the number of contributing staff members were calculated. Symptom frequencies were summarized for each BPSD domain, and the distribution of daily symptom counts was examined to assess variation across residents. Time-stamped entries enabled analysis of registration frequency across shifts and adherence patterns across units. Because the study aimed to assess feasibility rather than effectiveness, inferential testing was limited to examining changes in the time taken to complete a shift registration. For each resident, shift-registration times (one completed shift-form, measured from form opening to submission) during the first (days 1 - 30) and last (days 61 - 90) 30-day intervals were compared using the Welch independent *t* test, which is robust when the variances are not equal [46]. Durations exceeding 5 minutes were treated as outliers and excluded (43 of 1623 shift registrations, 2.6%), as these likely reflected staff interruptions or forgotten submissions. All quantitative analyses were conducted in Python (version 3.12) using standard scientific computing libraries.

Qualitative Analysis

Qualitative data from dyadic interviews were analyzed using deductive qualitative content analysis following the approach described by Elo and Kyngäs [47]. The analysis proceeded in

XSL•FO
RenderX

3 stages: preparation, organizing, and reporting. In the preparation phase, transcripts were read repeatedly to obtain a comprehensive understanding of staff experiences. In the organizing phase, meaning units related to staff experiences of conducting daily symptom observations were identified and organized into a structured coding matrix informed by selected domains of the NASSS framework (see Multimedia Appendix 2 for an example).

Codes were iteratively compared, refined, and grouped into categories through discussions within the research team. In the reporting phase, these categories were organized within the corresponding NASSS domains, capturing staff perspectives on the feasibility, challenges, and perceived value of conducting daily symptom observations. Microsoft Excel (Microsoft 365 version) and Python (version 3.12) were used for data management, coding, and analysis. Coding was performed by JM. Each meaning unit was assigned a descriptive code that was then mapped to a generic category and to its corresponding NASSS domain; Multimedia Appendix 2 provides a worked example of this quote-to-code-to-category-to-domain chain. EO and TB reviewed a subset of coded segments and provided input on categorization, and points of uncertainty were discussed within the team until a shared interpretation was reached. To support the trustworthiness of the analysis, coding decisions were documented in the structured coding matrix and revisited iteratively in team discussions. We did not compute intercoder agreement statistics, as such measures are of limited interpretive value for deductive content analysis with categories prespecified from a theoretical framework.

Integration of Data

Following separate analyses of the 2 strands, integration was conducted in 3 procedural steps, following the joint-display approach described by Fetters et al [35]. First, findings from each strand were summarized within the 4 feasibility dimensions used in this study (implementation, practicality, acceptability, and integration). Second, quantitative and qualitative evidence pertaining to the same dimension were juxtaposed to identify points of convergence (where strands reinforced each other), complementarity (where strands addressed different facets of the same dimension), and divergence (where strands offered conflicting signals) [48]. Third, integrated meta-inferences were drawn within each NASSS domain to interpret why the observed feasibility patterns emerged, drawing jointly on registration data and staff accounts. A joint display summarizing the integrated evidence per feasibility dimension is provided in Multimedia Appendix 3.

Results

Participant Characteristics

Eight residents living with dementia and exhibiting symptoms of BPSD were included in the pilot study across 4 residential care units. Daily observations were conducted over a 90-day period using the Daily-BPSD tool. In total, 44 staff members contributed registrations to the system.

Table 1 presents residents' age and gender, along with the number of staff members involved in observations for each resident. During the study period, care staff completed 1623 shift registrations (one per resident per shift; 75% of the 2160 possible resident-shifts, that is, 8 residents × 90 days × 3 shifts), comprising 19,123 NPI item-level ratings, together with 2870 individually selected variable registrations (21,993 item-level registrations in total; see Multimedia Appendix 4 for the full list).

Table . Characteristics of people living with BPSD[a] residing in the participating residential care units, as well as the number of care staff using the tool during the data collection period.

Characteristics	Values
Residents, n	8
Age (years), mean (range)	84 (75 - 92)
Gender, n (%)	
Female	5 (63)
Male	3 (37)

Individually selected variable registrations, n	2870

[a]BPSD: behavioral and psychological symptoms of dementia.

[b]NPI: Neuropsychiatric Inventory.

The deductive content analysis yielded 1137 coded segments across the 5 dyadic interviews. As shown in Table 2, the coding was distributed across all 5 NASSS domains, with the *adopters* and *organization* domains most prominently represented, followed by *technology*, *value proposition*, and the *condition*. The following sections present findings within each domain.

XSL•FO
RenderX

Table . Overview of NASSS[a] framework coding across 5 interviews (N=1137 coded segments).

NASSS domain	Segments, n (%)	Generic categories
The Organization	319 (28.1)	Registration routine (n=130), workflow (n=118), team discussion (n=34), decision-making process (n=19), communication (n=9), scalability (n=7), the BPSD[b] registry (n=2)
The Condition	75 (6.6)	Symptom presentation (n=41), symptom assessment (n=18), appropriate symptoms (n=10), dementia (n=6)
The Technology	231 (20.3)	Usability (n=96), registration device (n=42), information boxes (n=32), improvement suggestions (n=30), technical problems (n=25), zero function (n=5), missing data (n=1)
The Value Proposition	179 (15.7)	Perceived value (n=78), changed care practices (n=49), statistics use (n=42), data quality (n=10)
The Adopters	333 (29.3)	Competence (n=72), new employees (n=45), colleagues' views (n=42), knowledge of residents (n=39), engagement (n=37), knowledge development (n=34), expectations (n=29), barriers (n=23), temporary staff (n=12)

[a]NASSS: nonadoption, abandonment, scale-up, spread, and sustainability framework.

[b]BPSD: behavioral and psychological symptoms of dementia.

Domain: The Organization

Organizational routines shaped how Daily-BPSD registrations were carried out in practice. As context for the registration patterns presented below, day shifts typically comprised 3 staff members per unit, with 1 designated to complete the shift registration; these shift registrations were usually completed toward the end of the shift. Staff occasionally consulted colleagues to clarify observations for residents with whom they had less contact.

Units used different strategies to assign this responsibility. In some cases, it was integrated into existing routines by linking the task to other documentation responsibilities. As staff members described, "When we sit down to sign off medications and do our documentation, we added it as part of that routine as well" [Unit B, Staff Participant 3] and "Then we talk it through—the person on the green shift keeps track of the resident we're registering, checks how the past day has been. And the others who worked the day also contribute, reflecting and choosing which ratings fit" [Unit C, Staff Participant 6], illustrating how registration responsibilities were integrated into established practical arrangements within the unit. At night, staff members sometimes worked alone while covering multiple wards, meaning they held overall responsibility for several residents simultaneously.

Staff emphasized the importance of ensuring that all team members were introduced to the tool and felt confident using it, so that the process would not depend on a few individuals. Several also emphasized the importance of initiating new cases directly within the application, without waiting for administrator support.

As shown in Table 3, registration adherence was high, exceeding 70% for all shifts, except for one unit (unit B) where adherence was significantly lower.

XSL•FO
RenderX

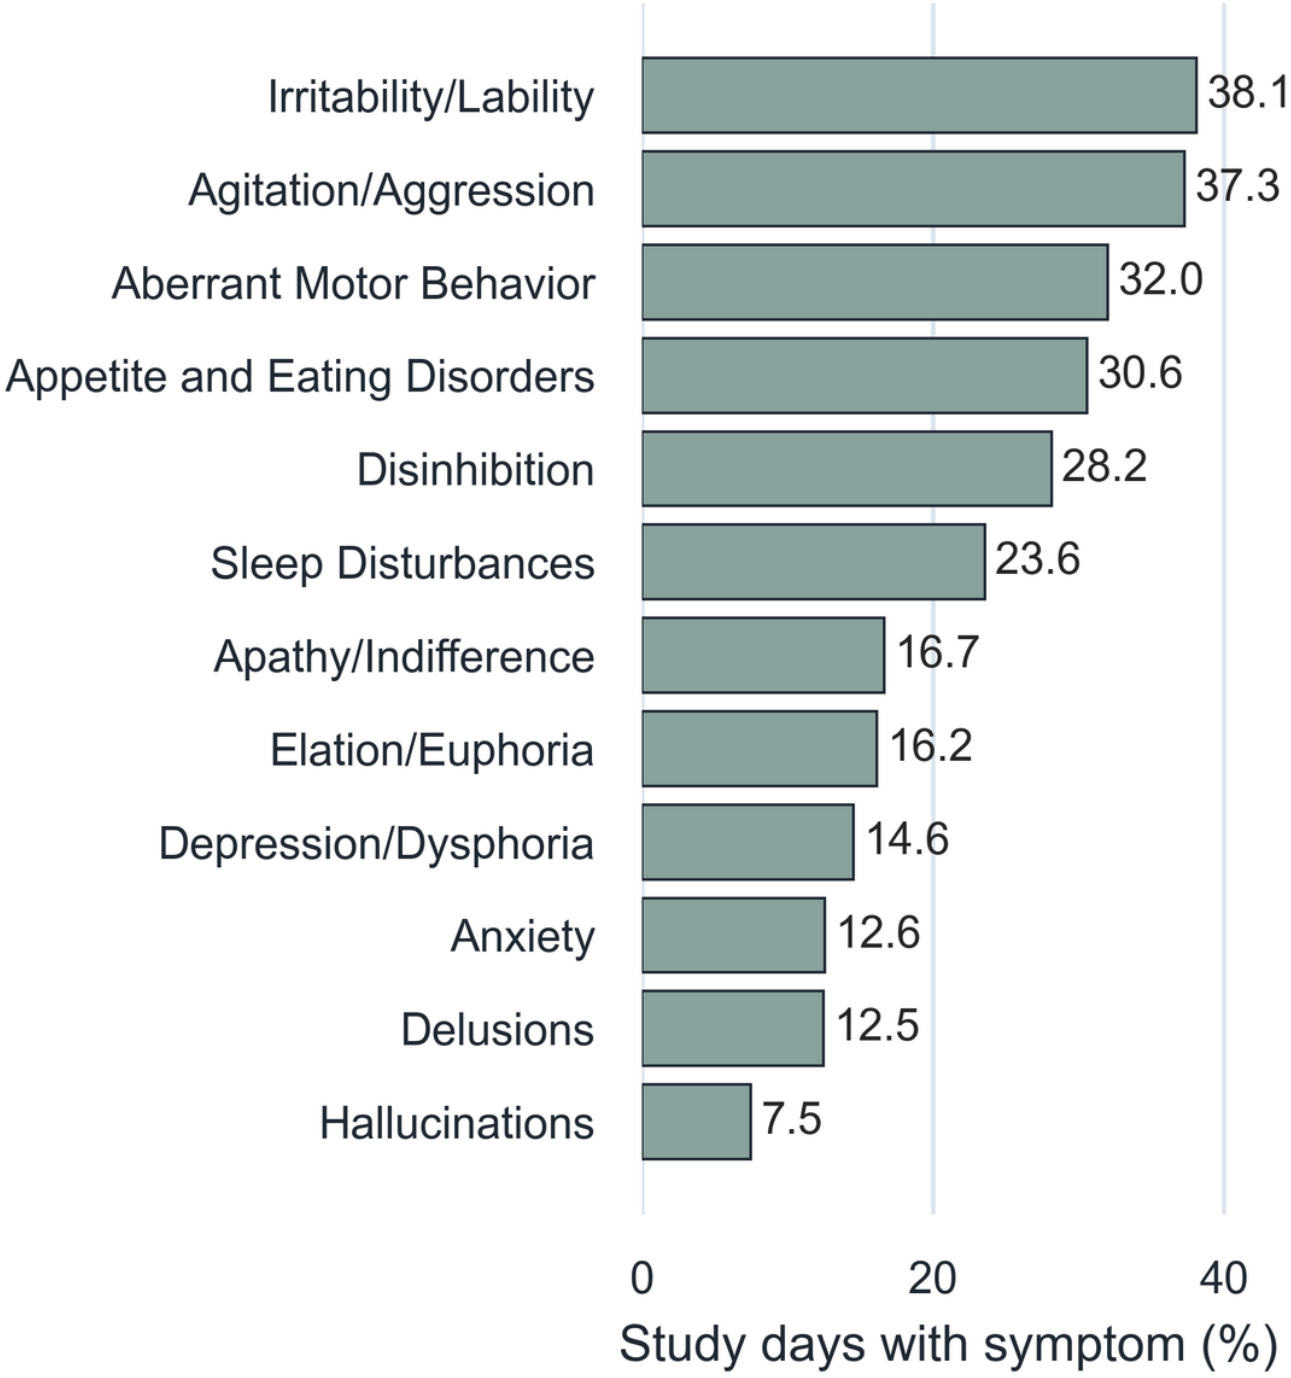
Table . Proportion of completed item-level NPI[a] registrations per resident and shift type during the study, calculated as the proportion of expected item-level NPI registrations for each resident–shift-type combination (denominator: 12 NPI domains × 90 study days = 1080 expected item-level registrations per resident per shift type). Residents are coded by unit (A-D) and a sequential resident study number (1-8).

Resident	Morning, %	Evening, %	Night, %	Overall, %	Staff, n
A1	91	90	76	85	12
A2	92	91	80	88	12
B3	58	66	13	46	10
B4	43	47	10	33	8
C5	89	83	98	90	7
D6	87	87	87	87	15
D7	87	86	92	88	15
D8	83	84	87	85	15
Mean	79	77	68	75	12[b]

[a]NPI: Neuropsychiatric Inventory.

[b]Total unique staff members across all residents: 44.

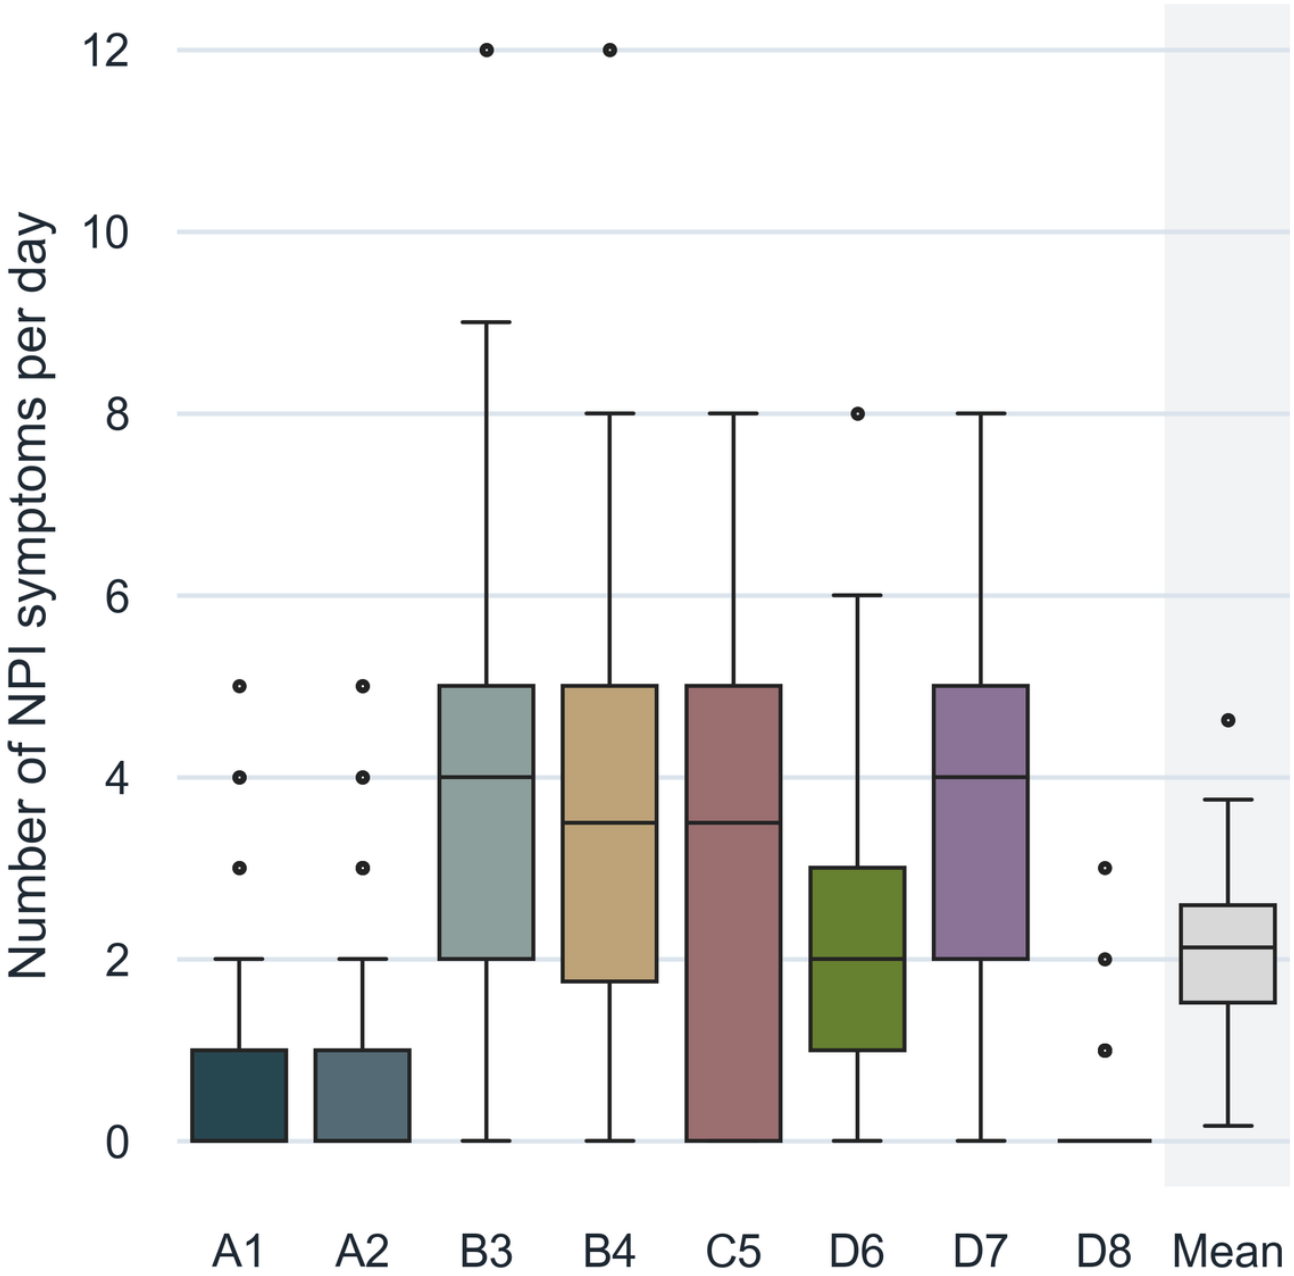
Analysis of registration frequency was conducted to examine changes in the number of completed item-level NPI registrations over the study period. Item-level NPI registration counts were divided into 3 intervals based on the number of days since the first registration for each resident: days 1 - 30 (n=6881), days 31 - 60 (n=6607), and days 61 - 90 (n=5635). The number of completed item-level registrations decreased in the final period compared to the earlier phases. The decline in the final interval coincided with the summer vacation period, when temporary staff without access to the tool were more common (see Strengths and Limitations).



Domain: The Condition or Illness

The occurrence of BPSD symptoms varied across residents, both in terms of overall frequency and in the types of symptoms observed. As shown in Figure 2, the proportion of days with observed NPI symptoms differed between symptom domains. Across the study period, staff recorded symptom ratings (severity 0 - 3) for the 8 included residents, who each contributed 52 - 90 observation days (mean 82.1). Irritability/lability (38.1%) and agitation/aggression (37.3%) were the most frequently observed symptoms, indicating that these behaviors were present on more than one-third of all registered days and represented the most pervasive symptoms. The least frequently reported symptoms included *delusions* (12.5%) and *hallucinations* (7.5%), suggesting that psychotic features were relatively uncommon in daily care observations.

The number of symptoms recorded per day varied across residents during the study period. Median daily symptom counts ranged from 2 to 3 for most residents, although the spread within individuals varied substantially. Some residents showed relatively stable distributions with limited day-to-day variation, whereas others displayed wider distributions and occasional peaks with higher symptom counts (see Figure 3).



XSL•FO
RenderX

Figure 2. Proportion of observation days with recorded Neuropsychiatric Inventory (NPI) symptoms during the study period. Bars represent, for each symptom, the equal-weight mean across the 8 residents of the proportion of each resident's observation days on which the symptom was recorded at least once (each resident contributing 52 - 90 observation days).

XSL•FO
RenderX

Figure 3. Number of reported Neuropsychiatric Inventory (NPI) symptoms per day across participants. Boxplots illustrate the distribution of daily recorded NPI symptoms for each resident across the 90-day study period. Each box represents IQR (25th-75th percentile), the horizontal line within the box indicates the median, whiskers extend to 1.5 × IQR, and dots represent outliers. The rightmost box "Mean (equal-weight)" shows the distribution of daily equal-weight means across all residents, where each resident contributes equally regardless of the number of registrations. Differences in medians and spread indicate variation in both overall symptom levels and day-to-day fluctuations among residents.

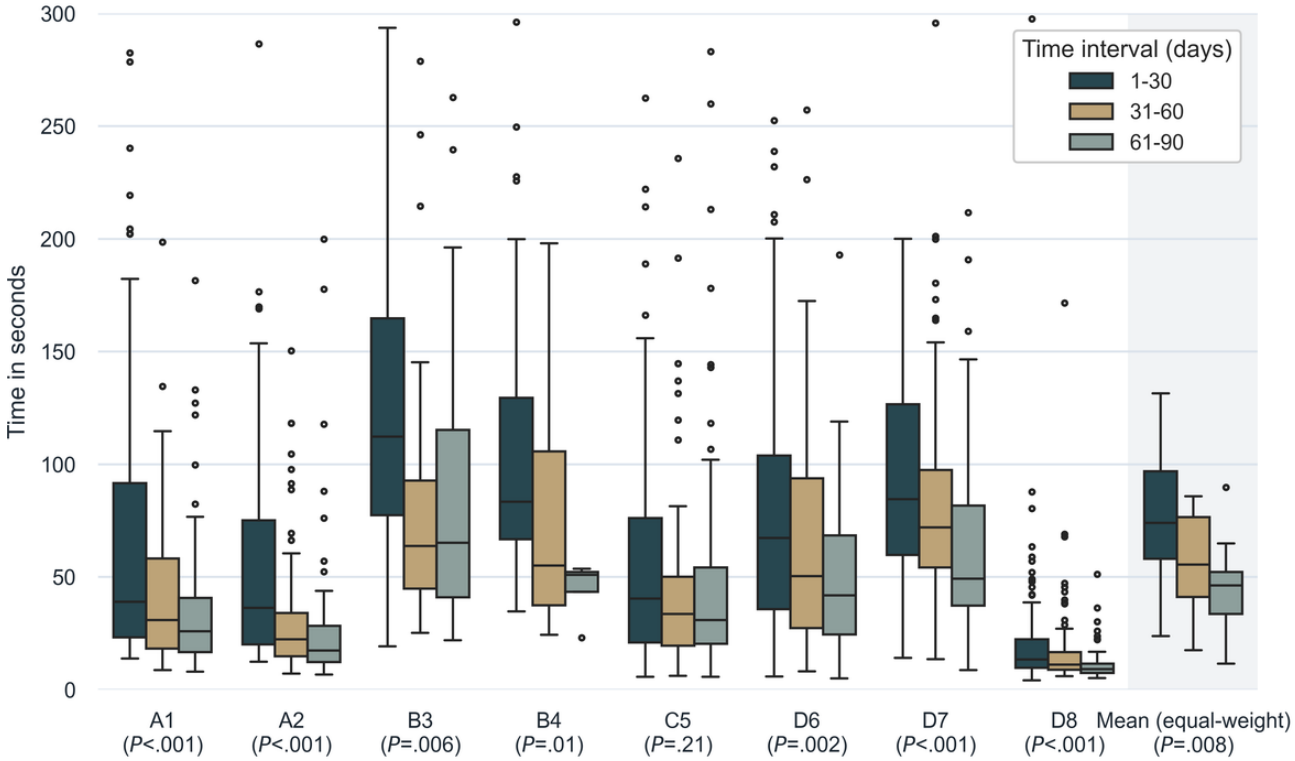
The nature of BPSD symptoms also shaped the interpretive demands placed on staff conducting daily observations. In the interviews, participants perceived certain symptoms, such as anxiety, hallucinations, and delusions, as particularly challenging to identify and assess in terms of severity. As one staff member reflected, "I think we've gotten better at distinguishing whether it's a hallucination or a delusion […] Sometimes it's a bit like, which is which, but then I find it helpful that you can read a little" [Unit D, Staff Participant 9]. The staff described that such situations often required close collaboration within the team to reach consensus and ensure reliable assessments. Knowing the individual resident was viewed as crucial for accurately interpreting symptoms, while temporary or new staff were said to struggle more with recognizing behavioral expressions correctly. Participants noted that the supportive texts (see Figure 1) integrated into the application were helpful when uncertainty arose. Although collective reflections based on group statistics were uncommon, participants reported that registering symptoms daily increased their confidence in assessing symptoms and provided better conditions for adjusting care to residents' needs.

Domain: The Technology

User Experience Feedback

Staff consistently described the Daily-BPSD tool as easy to use and time-efficient. The registration process was generally perceived as quick and straightforward, and few participants reported technical difficulties. As one participant explained, "It has been easy to log in, easy to fill in, and I think it doesn't take

XSL•FO
RenderX



very long" [Unit D, Staff Participant 7], reflecting the general perception that the tool could be integrated smoothly into daily routines. In the interviews, most staff described the smartphone as their most common device for completing registrations, with computers and tablets used occasionally. Night staff emphasized the usefulness of the existing feature, allowing all symptoms to be marked as "no observed occurrences" when a resident was asleep during the shift.

While the overall usability was rated positively, several participants noted areas where functionality could be improved. Some expressed a need for a clearer overview of remaining variables to register, as this occasionally led to omissions—particularly among the individually selected variables. Others highlighted that the information button linked to each symptom was highly appreciated, as it provided helpful definitions and guidance in moments of uncertainty. For future large-scale use, participants suggested adding administrative features to simplify the management of user accounts and the linking of individually selected variables to specific residents.

Registration Time

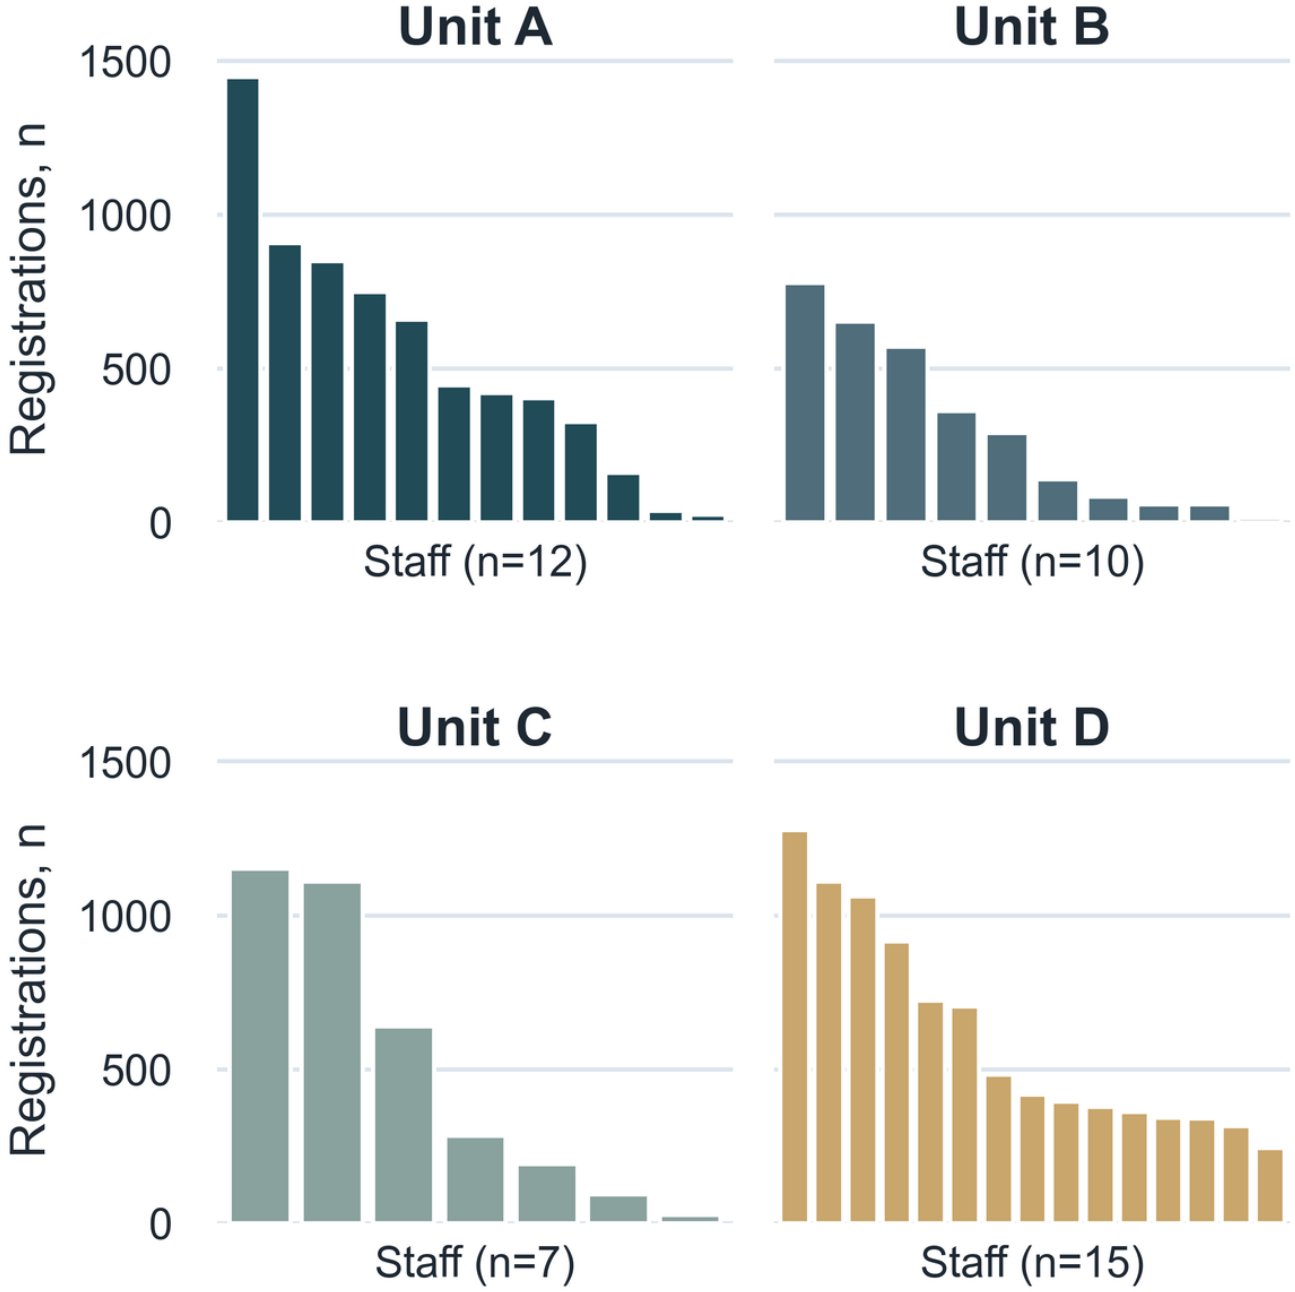
Consistent with staff perceptions that the tool was quick and easy to use, quantitative analysis of shift-registration times showed a reduction in the time required to complete a shift registration (measured from form opening to submission for one resident at one shift, ie, one complete shift-form) over the study period. Shift-registration times decreased significantly for all residents except C5 (P=.21) (see Figure 4). At the group level, the overall mean shift-registration time, calculated as an equal-weight average across residents (ie, each resident contributing equally regardless of the number of registrations), decreased from 77.1 seconds in the initial period to 46.2 seconds in the final period (P=.008), indicating that completing a full shift registration for all NPI domains together with any individually selected variables required less than 1 minute on average. This quantitative finding aligns with staff perceptions that the tool was quick to use in everyday practice.

Figure 4. Average shift-registration time per participant across three 30-day intervals. Distribution of shift-registration times per resident during the observation period (days 1 - 30, 31 - 60, and 61 - 90). Each box represents IQR (25th-75th percentile), the horizontal line within the box indicates the median, whiskers extend to 1.5 × IQR, and dots represent outliers. Color shading distinguishes the 3 time intervals. *P* values indicate Welch *t* test comparisons between the first and last interval. The category "Mean (equal-weight)" represents the distribution of daily means, with each resident weighted equally regardless of the number of registrations.

Domain: The Value Proposition

Participants described several ways in which daily symptom registration created value in their work. Staff reported that the process of assessing symptom severity on a daily basis increased their understanding of BPSD and strengthened their confidence in recognizing and discussing behavioral changes. As one participant expressed, "Then maybe you've understood that now she's probably going to get angry, because you've seen that it happens every time, so maybe it's washing her hands that triggers it" [Unit C, Staff Participant 6], illustrating how repeated symptom assessment was perceived as a learning process that increased staff awareness of behavioral changes. A reduction in average shift-registration time over the study period (see Figure 4) may also reflect increasing familiarity with both the tool and the symptom domains. Some participants also saw potential in using the aggregated data for team discussions. As one staff member noted, "I think that should have been the goal at team meetings, to bring up those statistics and see that he is much calmer when he has done this" [Unit A, Staff Participant

XSL•FO
RenderX



1]. However, only a few participants reported that the collected statistics had been actively used to adjust care for individual residents, although this was not an intended component of the pilot. Most participants nevertheless felt that the structured daily observational routine had clear potential to support both staff and residents if adopted more broadly in practice.

None of the participants raised economic issues, consistent with the study design, as they did not have financial responsibilities within their roles.

Domain: The Adopters

Participants emphasized the importance of engaging all staff members in the use of Daily-BPSD to ensure consistent registrations and shared ownership of the process. On some units, however, the registration effort was unevenly distributed: although all staff were expected to contribute, a few individuals carried out most of the registrations while others contributed comparatively little. As illustrated in Figure 5, the number of item-level registrations varied considerably among staff members within each unit, reflecting participants' descriptions that some individuals took greater responsibility for completing Daily-BPSD registrations than others.

Figure 5. Number of Daily-BPSD item-level registrations per staff member across the 4 participating units. Each bar represents a unique staff member.

Participants also emphasized the importance of involving other health care professionals, such as nurses, occupational therapists, and physiotherapists, to improve the multidisciplinary value of Daily-BPSD. As one participant noted, "Personally, I think it's better when everyone is involved. The more people you have, the more you can bounce ideas around. And then everyone is informed. Everyone has the same goal" [Unit C, Staff Participant 4]. Some noted that nurses currently rely on separate

XSL•FO
RenderX

documentation systems, which limit information sharing and hinder the integration of Daily-BPSD data into broader care planning.

Some participants also expressed that Daily-BPSD might, in the long term, facilitate registrations in the national BPSD Registry by providing more structured, up-to-date information for use in formal assessments.

Integrated Findings

Integration synthesized quantitative registration data with qualitative staff accounts within each of the 4 feasibility dimensions, characterizing each as showing convergence, complementarity, or divergence as defined in the Methods; a joint display summarizing the integrated evidence per dimension is provided in Multimedia Appendix 3.

For *implementation*, overall adherence of 75% varied substantially between units, with resident-level adherence ranging from 33% to 90% (Table 3). The qualitative data complemented this pattern by identifying two contrasting ways of organizing registration responsibility, as a shared task integrated into existing documentation routines, or as a task concentrated in a few individuals and therefore vulnerable to staffing disruptions, that plausibly underlie such between-unit variation.

For *practicality*, the reduction in shift-registration time from approximately 77 to 46 seconds (P=.008) converged with staff descriptions of the routine as quick, easy to log into, and naturally fitted to the closing routines of a shift.

For *acceptability*, quantitative adherence indicated *that* the routine was carried out, while qualitative data described *why* staff found it worth carrying out: reflection prompts, increased symptom awareness, and improved team conversations about residents. Complementarity dominated convergence here. A divergent signal also emerged: although staff perceived the routine as valuable, few reported that aggregated registration data had been used to actively adjust care during the pilot, suggesting that perceived value preceded actual use.

For *integration* into existing workflows, adherence differed markedly between units (Table 3). The qualitative accounts described how registration was fitted into a unit's existing routines, by linking it to documentation or medication tasks and designating a staff member per shift to complete it, mechanisms that plausibly account for how readily the routine was absorbed into established workflows. Across the 4 dimensions, the convergent design surfaced not only points of agreement but also complementary and divergent signals that the quantitative data alone could not have revealed.

Discussion

Principal Findings

This pilot study examined the feasibility of integrating structured daily observational routines, supported by digital documentation, into residential dementia care, and also described the variation in BPSD registrations between residents and from day to day. Across the 4 feasibility dimensions, the primary outcome of *implementation* was supported by an overall adherence of 75% across shifts (range 33% - 90% between residents), indicating that structured daily symptom registration is achievable in routine care but exhibits substantial between-unit variation. *Practicality* was indicated by a reduction in shift-registration time from approximately 77 to 46 seconds over the 90-day period, consistent with staff accounts of the tool as quick and easy to use. *Acceptability* was reflected in staff descriptions of perceived value, increased symptom awareness, and meaningful contribution to their work. *Integration* into existing workflows differed between units, paralleling adherence patterns and reflecting differences in how registration responsibility was incorporated into established routines. Beyond feasibility, the data showed substantial variation in BPSD: NPI symptom prevalence ranged from 7.5% (hallucinations) to 38.1% (irritability/lability), and daily symptom counts varied both between and within residents, supporting the rationale for structured high-frequency observation as a means of capturing meaningful symptom variability.

A fundamental tension exists between the rapid fluctuation of BPSD and the episodic nature of current assessment systems. The strong adherence observed across most units shows that structured, frequent observational documentation does not conflict with routine dementia care, even in settings with workload and staffing challenges. The findings provide preliminary support for the argument that more frequent observational practices may help address the documentation gap between daily symptom dynamics and formal assessment systems [33,49].

At the same time, the decline in registrations during periods with increased temporary staffing highlights an important organizational vulnerability. Structured observational routines may be more sustainable when staff work within shared responsibilities and established workflows. In this study, some units integrated the registration task into collective routines, while others relied more on individual initiative. The considerable variation in individual registration activity within units suggests that integrating high-frequency documentation as a shared professional responsibility, rather than a task carried by a few committed individuals, remains a key implementation challenge in residential care settings.

The variation in completion rates also suggests that local organizational characteristics, rather than shift type alone, influenced adherence. Units with lower adherence, particularly during night shifts where staff sometimes worked alone across multiple wards, may require additional support to ensure consistency. This aligns with implementation research emphasizing that digital innovations become integrated into everyday workflows, through leadership engagement and ongoing reinforcement within teams [50,51].

The results also contribute to the discussion on tacit knowledge in long-term care. Staff described how conducting structured daily symptom assessments enhanced their awareness and reflective engagement with BPSD. This suggests that formalizing observational routines may not only stabilize documentation but also make previously tacit clinical judgments more explicit by encouraging staff to regularly articulate, compare, and reflect on their assessments of residents'

XSL•FO
RenderX

symptoms. At the same time, participants reported difficulties distinguishing between overlapping symptoms such as anxiety and agitation or hallucinations and delusions. Such challenges echo previous research demonstrating the interpretive complexity of BPSD assessment, even among experienced professionals [30,52]. Structuring observation does not eliminate interpretive uncertainty; rather, it makes it more visible and underscores the need for shared definitions and continuous training. Viewed through the NASSS framework, these findings illustrate how the adopter and condition domains interact: the interpretive complexity inherent in BPSD (condition) places demands on staff competence and confidence (adopters) that cannot be resolved by technical solutions alone.

Taken together, the findings indicate that when high-frequency data collection is applied to observation-based, subjectively interpreted phenomena, the conditions for feasibility differ from those of instrumental monitoring: sustainability was shaped less by technical infrastructure than by organizational continuity and shared professional practice. In this sense, structured daily observational documentation functions as a bridge between informal, experience-based knowledge and formalized assessment systems, and may complement existing quality registers by rendering day-to-day fluctuations more systematically visible without replacing professional judgment. Consistent with its feasibility focus, the study characterizes the conditions under which such documentation can be carried out but did not evaluate care outcomes: although staff reported increased symptom awareness and saw potential in using aggregated observations for team discussions, few had actively used the data to adjust care during the study period. Whether these conditions translate into more attentive care, improved symptom management, or resident-level outcomes was not assessed and requires direct evaluation in subsequent studies.

Future research should examine how such routines function across different organizational settings and over longer periods, the role of individualized staff-selected variables in capturing person-specific behavioral patterns, and how observational practices can be scaled and adapted across diverse care contexts.

Strengths and Limitations

A key strength of this pilot study lies in its mixed methods design, which enabled a comprehensive examination of the feasibility and perceived value of structured, high-frequency observational documentation in dementia care. This design combined structured observational data on symptom patterns and adherence to the monitoring routine with qualitative accounts of staff experiences and the contextual conditions shaping its use.

However, several limitations should be acknowledged. The study involved a small, heterogeneous sample from a limited number of units in two municipalities in Sweden, limiting the transferability of the findings to other organizational contexts. Furthermore, the final study period (days 61 - 90) coincided with the summer vacation period, during which a higher proportion of temporary staff, who lacked access to the tool, were on duty, likely contributing to the observed decline in registrations. This seasonal effect should be considered when interpreting adherence patterns. Variation in adoption patterns among staff members also indicates that unit-level feasibility does not necessarily imply uniform individual-level engagement.

The absence of resident-reported outcomes limits conclusions regarding the experiential impact of structured documentation on person-centered care. Furthermore, the relatively short 90-day follow-up period restricts assessment of long-term sustainability and penetration—key implementation outcomes in digital health research. As a pilot study, the findings primarily inform feasibility rather than effectiveness.

Despite these limitations, the study provides preliminary empirical support for the feasibility of integrating structured daily observational routines into residential dementia care and offers a foundation for further refinement and evaluation in larger-scale studies.

Conclusions

This pilot study demonstrates that structured high-frequency observational documentation can be feasibly integrated into residential dementia care when supported by clear routines and team continuity. Integrating such practices into everyday work can establish a structured basis for systematic observation and team communication; whether this translates into earlier detection of behavioral changes or improved care quality requires further evaluation in studies designed to assess clinical and person-level outcomes.

The findings highlight that successful implementation depends less on technical functionality and more on organizational readiness, staff competence, and time allocated for reflection. Although Daily-BPSD served as the empirical platform in this study, the broader contribution concerns the feasibility of structured daily symptom documentation as a complement to existing quality registers. Such approaches may provide a more frequent and detailed informational basis for ongoing care processes; whether this can support more proactive and person-centered dementia care in practice remains an empirical question for future research.

Acknowledgments

We thank the unit managers and residential care staff who participated in this study for sharing their time and insights. Their contributions were essential for this study and for deepening our understanding of its use in everyday dementia care.

The authors declare the use of generative AI in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to generative AI tools under full human supervision: code optimization, visualization, proofreading and editing, translation, reformatting, and publication support. The generative AI tool used was Claude Opus 4 (Anthropic). Generative AI was used only to support language editing, translation, formatting, and manuscript preparation. All

study design, data collection, analysis, interpretation, and conclusions were carried out by the authors, who reviewed and verified all AI-assisted text and take full responsibility for the content. Generative AI tools are not listed as authors and do not bear responsibility for the final outcomes.

Funding

Grants were received from FORTE: the Swedish Research Council for Health, Working Life and Welfare (registration number 2021-01792). Open access funding provided by Jönköping University.

Data Availability

The datasets generated and analyzed during this study are not publicly available and cannot be shared. The data comprise sensitive personal data concerning health, namely daily registrations of behavioral and psychological symptoms for individuals living with dementia, together with verbatim transcripts of interviews with care staff. Under the terms of the ethical approval granted by the Swedish Ethical Review Authority (Dnr 2022-04509-01) and the consent obtained from participants and their legal representatives, and in accordance with the EU General Data Protection Regulation, these data may not be transferred outside the research team. Given the small and specific study population, the risk of reidentification cannot be excluded even from deidentified data; for this reason, the data cannot be made available, including upon individual request. The analysis code is available from the corresponding author on reasonable request.

Conflicts of Interest

The Daily-BPSD application was developed collaboratively by the author team, with technical implementation by JM. The team, therefore, has a potential intellectual stake in the tool, which is disclosed here. Several steps were taken to limit its influence. The study aims and design were specified in the ethics application before data collection. During the registration period, JM’s contact with staff was limited to technical support and did not extend to influencing what they registered, so the registration data were generated independently of the developers. JM conducted the interviews together with EO and TB, and JM performed the coding, with EO and TB reviewing a subset of coded segments and providing input on categorization. Because the intellectual stake is shared across the whole team, these safeguards mitigate individual rather than team-level bias. No other conflicts of interest have been declared.

Effect of an Intersectoral Telemedicine Intervention on Hospitalization in Nursing Home Patients: Specification Curve Analysis of a Stepped Wedge Cluster Randomized Trial

Abstract

Background: The use of emergency medical services in Germany has significantly increased, particularly for nonemergency cases. This issue becomes especially relevant for nursing homes, where staff is confronted with resource shortages and organizational challenges, making emergency medical services involvement a common course of action. This leads to potentially avoidable hospitalizations for nursing home residents and exposes them to severe health risks, such as nosocomial infections. To address this, we developed the Optimal@NRW project, implementing an innovative intersectoral telemedicine intervention that includes an early warning system and mobile nonphysician medical assistants in order to enable outpatient treatment in acute medical cases for nursing home residents. We hypothesize that hospitalizations could be significantly reduced, as patients could be treated on-site in the absence of a life-threatening emergency.

Objective: This study aims to determine the effect of an intersectoral telemedicine-based intervention for acute care situations on hospitalization among residents in nursing homes.

Methods: We conducted a prospective multicenter cluster-randomized stepped wedge trial from May 2021 to April 2023 across 24 nursing homes in western Germany. Nursing homes were randomly assigned to one of four sequences and followed over eight 3-month periods. All sequences crossed stepwise from the control to the intervention phase. We collected primary data in an electronic patient record and claims data from statutory health insurance funds. In a specification curve analysis, we evaluated the intervention effect using multiple mixed-effects regression model specifications with varying modeling approaches, datasets, dependent and independent variables, and operationalizations.

Results: The number of participants ranged from 158 to 285 nursing home residents per sequence and period, totaling 1151 participants in the control phase and 1271 participants in the intervention phase. A total of 1260 regression models were analyzed. Approximately two-thirds of all models exhibited a negative (ie, protective) intervention effect. However, no models exhibited a statistically significant (ie, $P<.05$) intervention effect. The distribution of effect direction and size differed by modeling approach, choice of outcome, and dataset used.

Conclusions: Our results do not support the hypothesis of a significant reduction of hospitalizations among nursing home residents. The effectiveness of the intervention may have been compromised by external factors such as a flood disaster in the study region and the COVID-19 pandemic, which introduced unforeseen challenges. Future studies should prioritize targeted outcomes (potentially avoidable hospitalizations) that align with the specific intervention mechanism, while also allowing for extended implementation periods to ensure that interventions reach their full potential.

Introduction

The demand for nursing and medical care for nursing home residents (NHR) is steadily increasing due to demographic change and the rising prevalence of chronic diseases, multimorbidity, and care dependency [1]. In Germany, approximately 4.9 million people currently require nursing care, with over half being older than 80 years [2]. Geriatric and multimorbid NHR are significantly sicker compared to older adults living outside such facilities and have higher rates of contact with health care providers [3]. Over the past decade, the use of emergency medical services in Germany has increased substantially [4]. Staffing shortages and organizational challenges in nursing homes, as well as inadequate care capacities in outpatient settings, often result in potentially avoidable hospitalizations for NHR in nonemergency situations, exposing residents to risks like nosocomial infections [5,6], delirium [7,8], and reduced functional capacity [9,10]. This trend is reflected in concepts such as ambulatory care-sensitive conditions (ACSC), core ambulatory care-sensitive conditions (CACSC) [11], and nursing home-sensitive conditions (NHSC) [12], which identify conditions where appropriate on-site or outpatient care could have avoided hospital admission.

These potentially avoidable hospitalizations not only place a financial burden on solidarity-based health care systems [13,14], but also increase costs for municipalities to provide emergency medical services such as ambulances and emergency response vehicles. Furthermore, the growing pressure on nursing homes, driven by societal changes and staff shortages, highlights the need for innovative care models. An intersectoral approach involving all relevant stakeholders is crucial for improving acute care for NHR, as hospital admissions affect not only the nursing homes but also emergency departments, ambulance services, and general practitioners (GPs).

Telemedicine has significant potential to transform acute care by enabling efficient, needs-based medical services across spatial and temporal barriers, optimizing resource use and access, particularly in rural or underserved areas [15,16]. During the COVID-19 pandemic, there was a significant increase in the use of telemedicine in Germany [17]. However, its widespread implementation faces challenges in German nursing homes such as regulatory constraints, reimbursement issues, and limited information technology infrastructure with problems regarding interoperability [18,19]. For instance, it was not compulsory for nursing homes to be connected to the telematics infrastructure until July 2025 (§ 341 (8) of Book V of the German Social Code) [20], which is intended to facilitate secure and efficient data exchange within the health care system. This leads to a fragmented landscape of digitalized medical documentation in nursing homes.

To address these challenges, we designed and implemented an innovative intersectoral telemedicine intervention aimed to enable outpatient treatment for NHR for acute medical conditions. Its effectiveness was evaluated through a prospective multicenter cluster-randomized trial with an open cohort stepped wedge design. The intervention was carried out in 24 nursing homes across the Aachen, Düren, and Heinsberg regions in western Germany, next to the Dutch and Belgian borders, covering both urban and rural areas. In this paper, we analyze the effect of the Optimal@NRW intervention on the hospitalization of NHR through the use of specification curve analysis. In particular, we report the intervention effects from a total of 1260 regression models, resulting from different modeling decisions (eg, choice of dataset, operationalizations, or independent variables).

Methods

Reporting

Our methodology follows the CONSORT (Consolidated Standards of Reporting Trials) statement for stepped wedge cluster randomized trials [21]. The checklist can be found in Checklist 1.

Trial Design

This paper is based on data from a prospective multicenter cluster-randomized trial with an open cohort stepped wedge design [22]. The stepped wedge design was chosen so that all participating nursing homes would eventually receive the intervention, thus fostering commitment to the project. A staggered rollout facilitated the practical and logistical implementation of the intervention. Our open cohort design aimed to recruit a substantial number of participants at the beginning of the trial, while adding more participants during the course of the trial to balance the high expected mortality rates among NHR.

Participants were clustered by nursing home; these clusters were summarized into 4 sequences. All nursing homes started in the control phase, in which participants received standard outpatient care for NHR. Sequences then transitioned stepwise from control to intervention phase, with the timing of the transitions randomized (Figure 1). Each step covered a 3-month interval, and all nursing homes participated in at least 2 intervals (6 mo) in both the control and intervention phases to ensure adequate data collection for each phase. The study took place over 2 years (May 2021 to April 2023), with 8 steps and a total of 24 nursing homes (clusters) across the 4 sequences. The transition phase between the control and intervention phases allowed for staff training and technical setup; data collected during this phase were excluded from our analysis.

Month	1-3	4-6	7-9	10-12	13-15	16-18	19-21	22-24
Sequence 1 7 Clusters								
Sequence 2 5 Clusters								
Sequence 3 6 Clusters								
Sequence 4 6 Clusters								

Participants and Data Collection

Potential study participants were included based on the predefined eligibility criteria described in Textbox 1. Recruitment was carried out by the study team within the participating nursing homes (clusters). Following the stepped wedge open cohort study design, participants were enrolled both at the beginning of the study and continuously throughout the study period. All participants gave their written consent before data collection.

Textbox 1. Inclusion and exclusion criteria of the Optimal@NRW trial.

Inclusion criteria:

- ≥ 18 years of age
- Residence in a participating nursing home
- Signed consent form for study participation and data transfer or consent form signed by carers (for residents who are unable to give consent)

Exclusion criteria:

- <18 years of age
- No residence in a participating nursing home
- Nursing home residents in a dependent or employment relationship with a member of the study team
- Lack of clarity about nursing home residents' capacity to give consent
- Nursing home residents placed in a nursing home by order of the authorities or the courts

We received data on the participants from two sources. First, we used primary data from a study database. The study database contained demographic information on the participants, such as year of birth, sex, and date of death, as well as insurance status and hospitalization data. Primary data were collected by study nurses employed by each nursing home. Second, we received claims data from five statutory health insurance (SHI) funds. The claims data contained demographic information as well as morbidity and hospitalization data. For all study participants who were insured with one of the participating SHI funds, the claims data were provided for the study period as well as an additional 2-year preobservation period. In addition to the information from the study database and claims data, the study nurses also measured the Barthel Index (BI), a patient-reported endpoint to describe the ability for activities of daily living [23], at two time points: at study enrollment (t0) and at the transition to the intervention phase (t1).

However, these two datasets were incompatible with each other for several reasons, with different advantages and disadvantages. First, the primary dataset covered all study participants, while the claims dataset included data only from those participants who were members of one of the participating SHI funds. Second, some information (such as routinely collected morbidity data and data on hospitalizations before the study period) was available only in the claims dataset. Therefore, instead of merging the datasets, we performed the statistical analysis (described below) separately for the primary data and claims data.

Intervention

The Optimal@NRW project used an innovative, intersectoral intervention to improve acute medical care for residents of nursing homes and residential care facilities (hereafter collectively referred to as "nursing homes"). This intervention consisted of three levels.

First, a telemedical center was initialized at the University Hospital Aachen (UK Aachen) and was available 24/7 for telemedical consultations concerning the NHR. These consultations enabled 3-way communication between patients, nurses, and (tele)physicians. If necessary, mobile nonphysician assistants (nonphysician medical assistants [Nicht-ärztliche Praxisassistent*innen mit Zusatzaufgaben]; NäPa[Z]) were dispatched to perform delegable actions on-site. An electronic health record centralized patient information to ensure informed decision-making and coordination among all care providers.

Second, Optimal@NRW introduced a telemedicine approach via a "virtual hub," where nursing home staff could call the medical on-call service (116 117) in the event of an acute

XSL•FO
RenderX

medical situation involving an NHR. The medical on-call service then assessed the urgency of the situation using a structured initial medical assessment software [24] and determined the next steps. Alternatively, nursing home staff could contact the telephysicians of the UK Aachen directly.

Third, an early warning system (Frühwarnsystem) was implemented, involving routine monitoring of vital signs by nursing home staff, with data transmitted to the telemedicine center for continuous software-based assessment. Further intervention details can be found in the study protocol [25].

During the control phase, care in the participating nursing homes was provided as usual. In acute medical situations, nursing staff were responsible for making decisions independently. This typically involved either contacting a GP or calling the medical on-call service or an ambulance directly.

Sample Size

For the sample size calculation, we assumed an average of 2.8 days in hospital per patient-quarter based on hospitalization data for German nursing home patients from 2019 [26]. Based on estimates from medical experts at UK Aachen, we hypothesized that the number of days in hospital could be reduced by 30%. Informed by a prior study [27], the intracluster correlation coefficient was set at ρ=0.12. For 24 participating nursing homes, a significance level of α=.05, a power of 1-β=.90, and a SD of 4.5 resulted in a required sample size of 43 residents per nursing home per time point. Considering a 12% quarterly dropout due to high mortality [28] and other factors, the final adjusted sample size was 49 residents per nursing home per time point.

Randomization

We used stratified randomization at the nursing home level, taking into account bed capacity (small entities with <80 beds and large entities with ≥80 beds) and specialization in dementia care (yes or no) to ensure balanced group allocation. Additionally, block randomization was applied within these stratified groups to avoid imbalances in cluster distribution. The selection of eligible nursing homes was carried out in advance by the study team, while health economists from Bielefeld University, who were not involved in recruitment, data collection, or the design and implementation of the intervention, designed the allocation plan and performed the randomization process to minimize allocation bias. Nursing homes were informed of their assigned sequence by the study team before the start of the trial.

Objective and Outcomes

The primary objective of our analysis in this paper was to evaluate hospitalization in the intervention versus control phases. It was hypothesized that the intervention would lead to a significant reduction in hospital admissions and, therefore, a significant reduction in days in hospital (it is important to note that the intervention only affects the probability of hospital admission for patients in the nursing home and is not hypothesized to directly affect the length of stay for patients in the hospital).

Hospitalization was measured as a binary variable for each day spent in the nursing home by each patient, defined as 1 if the patient was admitted to the hospital on that day, and 0 otherwise. In addition to a dependent variable considering all hospitalizations, we also defined four further dependent variables, which operationalized potentially avoidable hospitalizations as ACSC hospitalizations, CACSC hospitalizations, NHSC hospitalizations, or same-day discharges (SDD). ACSC refers to a defined set of conditions for the general population in Germany that identifies potentially avoidable hospital admissions. The list is based on *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) and includes 40 *ICD-10* diagnoses (ACSC) and a core list of 22 *ICD-10* diagnoses (CACSC) [11]. Additionally, a list of NHSC, comprising 58 *ICD-10* diagnoses that frequently lead to avoidable hospitalizations in this patient cohort, has recently been finalized for Germany [12]. For each hospitalization, we also measured the duration in days (starting at 1 for SDD). All dependent variables available for analysis are shown in Textbox 2

Participant-level characteristics at baseline were summarized by study phase and by allocated sequence. The participant-level characteristics included gender, age, morbidity, and prior hospitalization. For morbidity and prior hospitalization, multiple operationalizations were available. All independent variables available for analysis in the primary and claims datasets are shown in Textbox 3.

XSL•FO
RenderX

Textbox 2. Available dependent variables. All variables are available at the patient-day level. Variables in the primary dataset were based on information from the study database; variables in the claims dataset were based on information from the statutory health insurance claims data.

Available dependent variables

- Hospitalization: binary variable that equals 1 if there was a hospitalization on the patient-day in question. Equals 0 otherwise.
- Ambulatory care-sensitive conditions (ACSC) hospitalization: binary variable that equals 1 if there was a hospitalization on the patient-day in question and the primary discharge diagnosis of that hospitalization is contained in the ACSC list of *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) codes. Equals 0 otherwise.
- Core ambulatory care-sensitive conditions (CACSC) hospitalization: binary variable that equals 1 if there was a hospitalization on the patient-day in question and the primary discharge diagnosis of that hospitalization is contained in the CACSC list of *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) codes. Equals 0 otherwise.
- Nursing home-sensitive conditions (NHSC) hospitalization: binary variable that equals 1 if there was a hospitalization on the patient-day in question and the primary discharge diagnosis of that hospitalization is contained in the NHSC list of *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) codes. Equals 0 otherwise.
- Same-day discharge (SDD) hospitalization: binary variable, equals 1 if there was a hospitalization on the patient-day in question and the patient in question was discharged on the same day. Equals 0 otherwise.
- Days in hospital: count variable measuring the number of days spent in hospital as the result of hospitalization on the patient-day in question. Equals 0 if there was no hospitalization on the patient-day in question.
- ACSC days in hospital: count variable measuring the number of days spent in hospital as the result of ACSC hospitalization on the patient-day in question. Equals 0 if there was no ACSC hospitalization on the patient-day in question.
- CACSC days in hospital: count variable measuring the number of days spent in hospital as the result of CACSC hospitalization on the patient-day in question. Equals 0 if there was no CACSC hospitalization on the patient-day in question.
- NHSC days in hospital: count variable measuring the number of days spent in hospital as the result of NHSC hospitalization on the patient-day in question. Equals 0 if there was no NHSC hospitalization on the patient-day in question.
- SDD days in hospital: count variable measuring the number of days spent in hospital as the result of SDD hospitalization on the patient-day in question. Equals 0 if there was no SDD hospitalization on the patient-day in question.

XSL•FO
RenderX

Textbox 3. Available independent variables. All variables are available at the patient-day level. Variables in the primary dataset were based on information from the study database; variables in the claims dataset were based on information from the statutory health insurance claims data.

Available independent variables with only one operationalization

- ID: factor variable, a pseudonym indicating the patient in question; nursing home: factor variable indicating the nursing home of the patient in question.
- Time: factor variable indicating the study quarter (period) of the patient-day in question.
- Study group: binary variable indicating the study phase (control or intervention) of the patient in question on the day in question.
- Gender: factor variable indicating the gender of the patient in question.
- Age: continuous variable obtained by subtracting the birth year of the patient in question from the year of the day in question and scaling around the mean.

Morbidity (five operationalizations of the morbidity of the patient in question)

- Factor variable obtained by splitting the most recent observation of the Barthel Index of the patient in question into three categories [29]: no disability (100), moderate disability (56-99), and severe disability (0 - 55).
- Factor variable obtained by splitting the most recent observation of the Barthel Index of the patient in question into five categories [30]: independence (100), slight dependence (91-99), moderate dependence (61-90), severe dependence (21-60), and total dependence (0 - 20).
- Continuous variable (available only in claims dataset) measuring the Charlson Comorbidity Index of the patient in question, calculated daily based on diagnoses during the 365 days prior to the day in question using the comorbidity package [31].
- Factor variable (available only in claims dataset) obtained by splitting the Charlson Comorbidity Index of the patient in question into 3 categories [29]: no comorbidities (0), moderate comorbidities (1-2), and severe comorbidities (3+).
- Factor variable (available only in claims dataset) measuring the care grade of the patient in question (integer between 0 and 5, assigned by the Health Insurance Medical Service according to § 15 and § 18 of the German Social Code, Book XI (SGB XI)) [32].

Prior hospitalization (two operationalizations of prior hospitalizations of the patient in question)

- Binary variable (available only in claims dataset) that equals 1 if the patient in question was admitted to the hospital at least once in the 365 days prior to the day in question. Equals 0 if otherwise.
- Count variable (available only in claims dataset) measuring the number of times the patient in question was admitted to the hospital in the 365 days prior to the day in question.

Statistical Methods

To estimate the effect of the intervention, we performed mixed-effects regression analysis. However, in specifying our regression model, we faced several modeling decisions that offered no clear correct choice. Instead of fitting only a single regression model, we addressed these issues by performing a specification curve analysis. In such an analysis, researchers report the results of all "reasonable specifications," defined as the set of model specifications that are "(1) sensible tests of the research question, (2) expected to be statistically valid and (3) not redundant with other specifications in the set" [33]. The estimated effect sizes from each model are then ordered by size and visualized in a diagram–the specification curve. Specification curve analysis can be considered a formal extension of the common practice of considering the robustness of results to model specification decisions [33]. For our analysis, we ran a total of 1260 separate regression models with different combinations of modeling approaches, datasets, dependent and independent variables, and operationalizations.

First, we needed to choose which modeling approach to use. For this, we considered three options: (1) a negative binomial count model for the number of hospital days at the patient-quarter level, (2) a negative binomial count model for the number of hospitalizations at the patient-quarter level, and (3) a binomial model for hospital admission at the patient-day level. For the count models, we used a log link function. For the binomial regression, we used a complementary log-log (*cloglog*) link function. Unlike logit or probit link functions, *cloglog* link functions are asymmetrical and are therefore most appropriate when the probability of an event is very high or very low [34-36]. This was the case for our data, as there was no hospitalization on the vast majority of person-days in both datasets.

Second, as the primary data collected by the study team and the claims data provided by the SHI funds were incompatible, we needed to choose on which data to fit the regression model. Third, after choosing a dataset, we needed to choose how to operationalize the outcome: as measuring all, ACSC, CACSC, NHSC, or SDD hospitalizations/days in hospital. For ease of reference, we refer to models using ACSC hospitalizations as the outcome as "ACSC models" (and so on for the remaining operationalizations).

In each model specification, we included the variables study group (the treatment variable), time (to model secular trends), nursing home, and id (to model cluster- and patient-level measurement using random intercepts). For the first and second modeling approaches (count models for the number of hospital days and the number of hospitalizations at the patient-quarter level), we also included a factor variable controlling for the time spent in the nursing home by each patient in a given quarter. However, we still needed to decide which combination of the

XSL•FO
RenderX

remaining available independent variables (gender, age, morbidity, and prior hospitalization) to use as control variables.

Finally, multiple operationalizations were available for two independent variables in one or both datasets, with no clear theoretical basis for choosing between these operationalizations. In particular, the primary dataset included two possible operationalizations of morbidity, while the claims dataset included five possible operationalizations of morbidity and two possible operationalizations of prior hospitalization (recall Textbox 3). For each modeling approach, all possible combinations of outcome and control variables amounted to a total of 5*2*2*3=60 model specifications on the primary dataset and 5*2*2*6*3=360 model specifications on the claims dataset. This yields a total of 420 model specifications per modeling approach and 1260 model specifications across all 3 modeling approaches. For each of these model specifications, we removed all patients who had missing values in at least one variable that was included in the model specification. The model formulas for each modeling approach on both datasets are illustrated in Textbox 4.

Textbox 4. Model formulas on the primary and claims datasets.

Primary dataset

1. negative binomial regression (patient-quarter level): hospital days (5 options)~study group+time+gender (2 options)+age (2 options)+morbidity (3 options)+nursing home (random intercept)+id (random intercept)
2. negative binomial regression (patient-quarter level): hospital admissions (5 options)~ study group+ time+gender (2 options)+age (2 options)+morbidity (3 options)+nursing home (random intercept)+id (random intercept)
3. cloglog regression (patient-day level): any hospitalization (5 options)~study group+time+gender (2 options)+age (2 options)+morbidity (3 options)+nursing home (random intercept)+id (random intercept)

For each modeling approach on the primary dataset: 5*2*2*3=60 possible formulas.(Note: for covariates, noninclusion is an option).

Claims dataset

1. negative binomial regression (patient-quarter level): hospital days (5 options)~study group+time+gender (2 options)+age (2 options)+morbidity (6 options)+prior hospitalization (3 options)+nursing home (random intercept)+id (random intercept)
2. negative binomial regression (patient-quarter level): hospital admissions (5 options)~study group+time+gender (2 options)+age (2 options)+morbidity (6 options)+prior hospitalization (3 options)+nursing home (random intercept)+id (random intercept)
3. cloglog regression (patient-day level): any hospitalization (5 options)~study group+time+gender (2 options)+age (2 options)+morbidity (6 options)+prior hospitalization (3 options)+nursing home (random intercept)+id (random intercept)

For each modeling approach on the claims dataset: 5*2*2*6*3=360 possible formulas. (Note: for covariates, noninclusion is an option).

For the first and second modeling approach (count models for the number of hospital days and the number of hospitalizations at the patient-quarter level), we calculated rate ratios by exponentiating the regression coefficients for the study group variable. Note that the rate ratios in the first modeling approach refer to the number of hospital days attributable to hospitalizations in a given quarter, not the number of hospital days that took place during the quarter.

The regression coefficients of the *cloglog* models in the third modeling approach do not allow for a straightforward interpretation in terms of log odds or odds ratios. Therefore, for the third modeling approach, we calculated the intervention effect on the average participant in terms of the yearly probability of hospitalization. This was determined by calculating the predicted daily (total, ACSC, CACSC, NHSC, or SDD) hospitalization probability in the control and intervention phases for a hypothetical participant with modal or mean values for all variables and subtracting the former from the latter (random effects were disregarded for this calculation). We then multiplied the resulting value by 365 to yield the predicted difference in additional (total, ACSC, CACSC, NHSC, or SDD) hospitalizations per 365 days spent in the nursing home between the intervention and control phases.

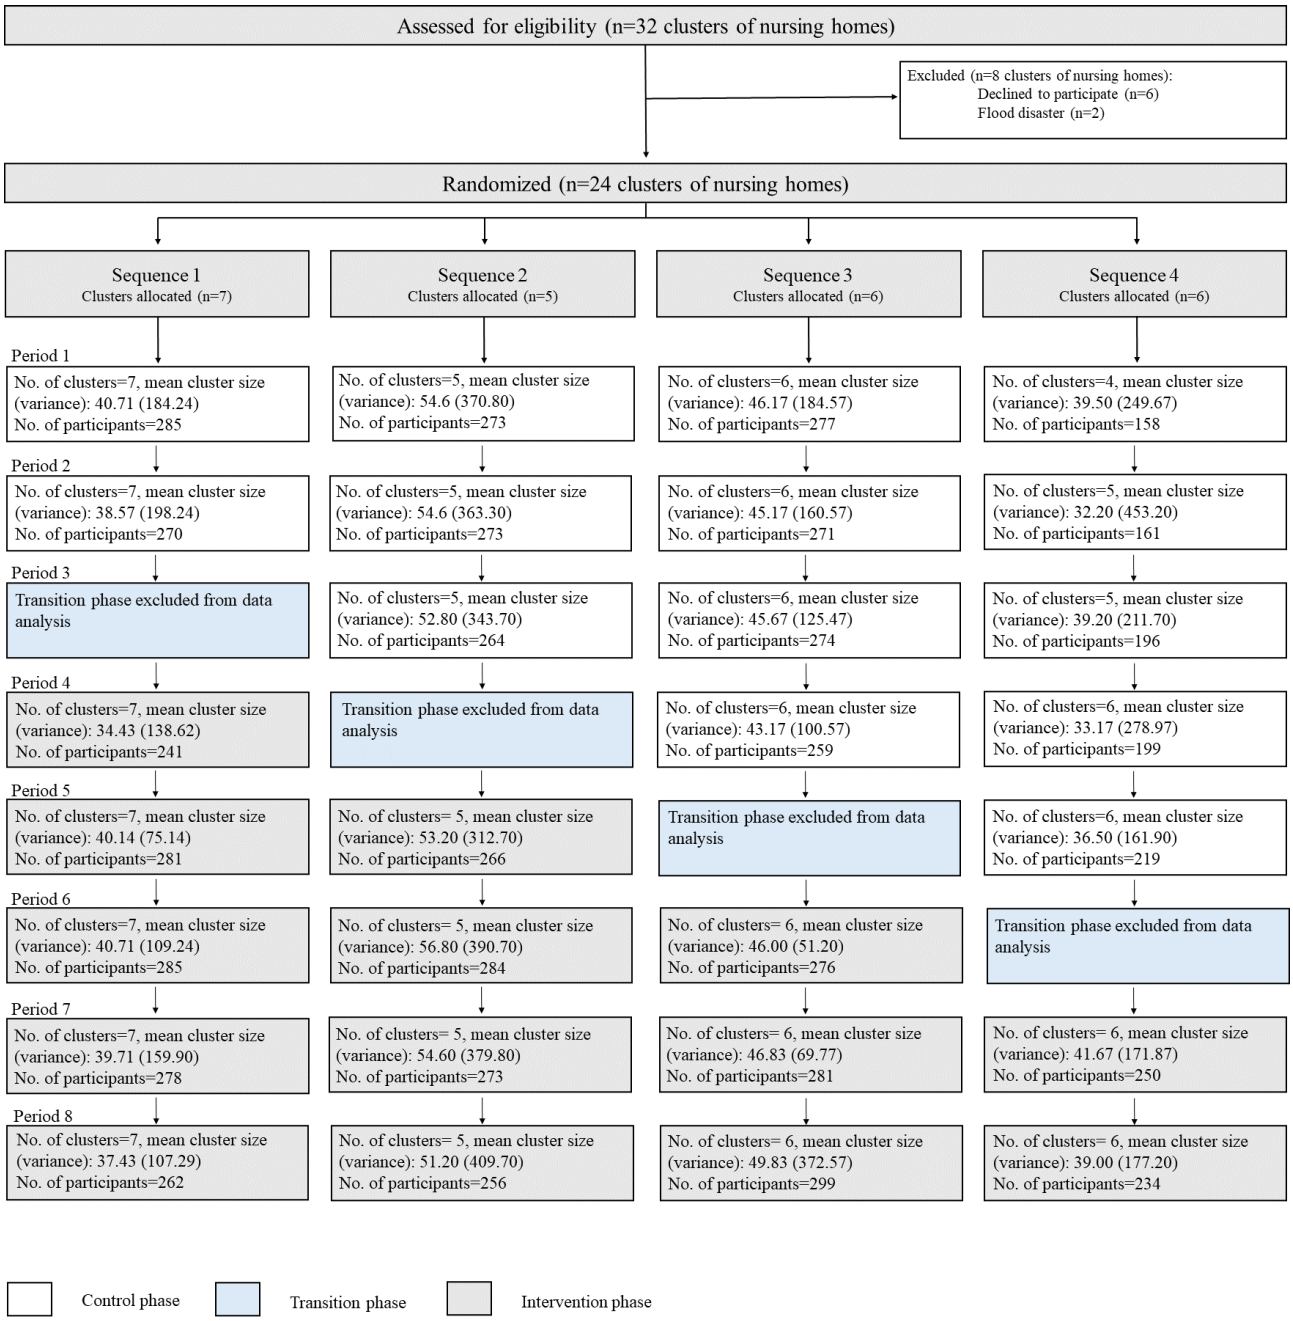
We processed the data and ran the regression models in the RStudio (Posit Software, PBC) environment using the tidyverse [37], comorbidity [31], and glmmTMB [38] packages and visualized the model configurations (choice of dataset, control variables, and variable operationalizations) and resulting intervention effects for each modeling approach in a specification curve using the specr package [39]. For each modeling approach, we also calculated the number and share of intervention effects by direction, the mean, minimum, and maximum size of the intervention effect, and the median, minimum, and maximum *P* value across all models.

Ethical Considerations

This study was approved by the Ethics Committee of the UK Aachen (CTC-A No. 19-019; EK 463/20). All participants provided informed consent before data collection, which covered both the primary and secondary datasets. The study adhered to the ethical principles outlined in the Declaration of Helsinki.

Primary data for the study were collected by study nurses in the participating nursing homes and stored in a study database, in accordance with the ethics committee approval. Claims data were received from participating SHI funds after authorization by the relevant bodies, including the Federal Office for Social Security (Bundesamt für Soziale Sicherung) and state-level supervisory offices, in accordance with German law. Both datasets were transmitted and stored in accordance with the European General Data Protection Regulation. Detailed descriptions of data security, storage, and transfer mechanisms,

XSL•FO
RenderX



as well as further information on the legal foundation of data collection and use, can be found in the study protocol [25]. The study was registered May 10, 2021, under ClinicalTrials.gov (NCT04879537). A study protocol was published September 27, 2022, in Trials following the SPIRIT checklist [25].

Results

Recruitment and Participant Flow

Figure 2 shows the participant flowchart, which illustrates the recruitment, randomization, and progression of clusters and participants through the study phases of our stepped wedge cluster randomized trial. Initially, 32 clusters of nursing homes were assessed for eligibility. Six nursing homes declined to participate, while 2 nursing homes had to cancel their planned participation after randomization had taken place due to a flood disaster in their region, which forced those homes to shut down operations temporarily. Therefore, 2 additional nursing homes were recruited for sequence 4 in periods 2 and 3. In total, 24 nursing homes participated (in four sequences containing between 4 and 7 nursing homes each). The number of participants assessed varied across periods, ranging from 158 to 285 individuals per sequence per period. Data from the transition phase was not used in our analysis and is therefore excluded from the flowchart.

Figure 2. Study flowchart of participants and nursing homes.

XSL•FO
RenderX

Baseline Characteristics

The baseline characteristics of participants in the control and intervention phases are shown in Table 1. In both the primary and claims datasets, there were more patients, more patient-days, and a slightly lower percentage of female participants in the intervention compared to the control phase. The phases were well balanced in terms of mean age of participants and mean BI (in the BI subgroup). In the claims dataset, participants in both phases also had a similar mean Charlson Comorbidity Index (CCI), median care grade, and number of prior hospitalizations (in the past year). The BI scores indicate that the participants are highly dependent on assistance in their daily lives, while the CCI scores indicate a high level of comorbidity.

As our study followed an open cohort stepped wedge design, some patients were enrolled in both the control and intervention phases, while others were enrolled only in the control phase or only in the intervention phase. As recommended by the CONSORT extension for stepped wedge trials [21], we therefore also summarized participants' baseline characteristics by allocated sequence in Table 2.

Outcome Measures

The primary outcomes of our analysis were the number of hospitalizations and days spent in hospital. A descriptive comparison of outcomes by study phase is provided in Table 3. As for the baseline characteristics, we also present the number of hospitalizations and days in hospital by allocated sequence in Table 4. Notably, although the claims dataset covers fewer patients than the primary dataset, the number of ACSC and CACSC hospitalizations (both total and per patient-year in the nursing home) is higher in the claims than in the primary dataset for each of the four sequences. Furthermore, the number of NHSC hospitalizations per patient-year is also larger in the claims dataset than in the primary dataset.

[a]SEQ: sequence.

[b]ACSC: Ambulatory care-sensitive condition.

[c]CACSC: Core ambulatory care-sensitive condition.

[d]NHSC: Nursing home-sensitive condition.

[e]SDD: Same-day discharges.

[f]NH: nursing home.

The same holds for days in hospital: the number of ACSC and CACSC days in hospital (both total and per patient) is higher in the claims than in the primary dataset, as is the number of NHSC days in hospital per patient. Notably, despite the claims dataset containing 643 fewer total hospitalizations than the primary dataset, it contained only 24 fewer days in hospital. Overall, these results indicate substantial differences in the quantity and quality of hospitalization data between the primary and claims datasets (ie, incomplete hospitalization information in the primary dataset), necessitating a separate analysis for each dataset.

Specification Curve Analysis

Modeling Approach 1: Count Models for Days in Hospital

For modeling approach 1, we ran a total of 420 count regression models with days in hospital as the dependent variable. Of these, one model failed to converge, leaving 419 models for analysis. To illustrate the effect of our modeling choices on the size and direction of the intervention effect, Figure 3 shows the specification curve for the 419 model specifications of modeling approach 1.

Figure 3. Specification curve for modeling approach 1. SDD: same-day discharges; NHSC: nursing home-sensitive conditions; CACSC: core ambulatory care-sensitive conditions; ACSC: ambulatory care-sensitive conditions; PG: care grade (German: Pflegegrad); CCI: Charlson Comorbidity Index; BI: Barthel Index.

The specification curve reveals that the operationalization of the outcome variable has the most noticeable influence on the size of the intervention effect. In particular, SDD models had the lowest rate ratios, while NHSC models had the largest rate ratios. The remaining model specification choices did not have as clear a systematic effect on the size of the intervention effect.

Table 5 shows the proportion of negative intervention effects, the mean, minimum, and maximum effect sizes as well as the median, minimum, and maximum *P* values for the 419 regression models: overall, by outcome variable, and by dataset. Over 71% (298/419) of regression models found a negative (ie, protective) intervention effect, with a mean rate ratio of 0.88. This intervention effect was nonsignificant for all 419 regression models, with a median *P* value of .54 (IQR .34-.75) (although some SDD models exhibited *P* values as low as .08).

NHSC models had the lowest proportion of negative effects (12/84, or less than 15%). Effect sizes (rate ratios) ranged from 0.56 to 1.57, with a mean rate ratio of 0.88. Models using the primary dataset had a higher proportion of negative effects (and a slightly lower mean rate ratio) than those using the claims dataset.

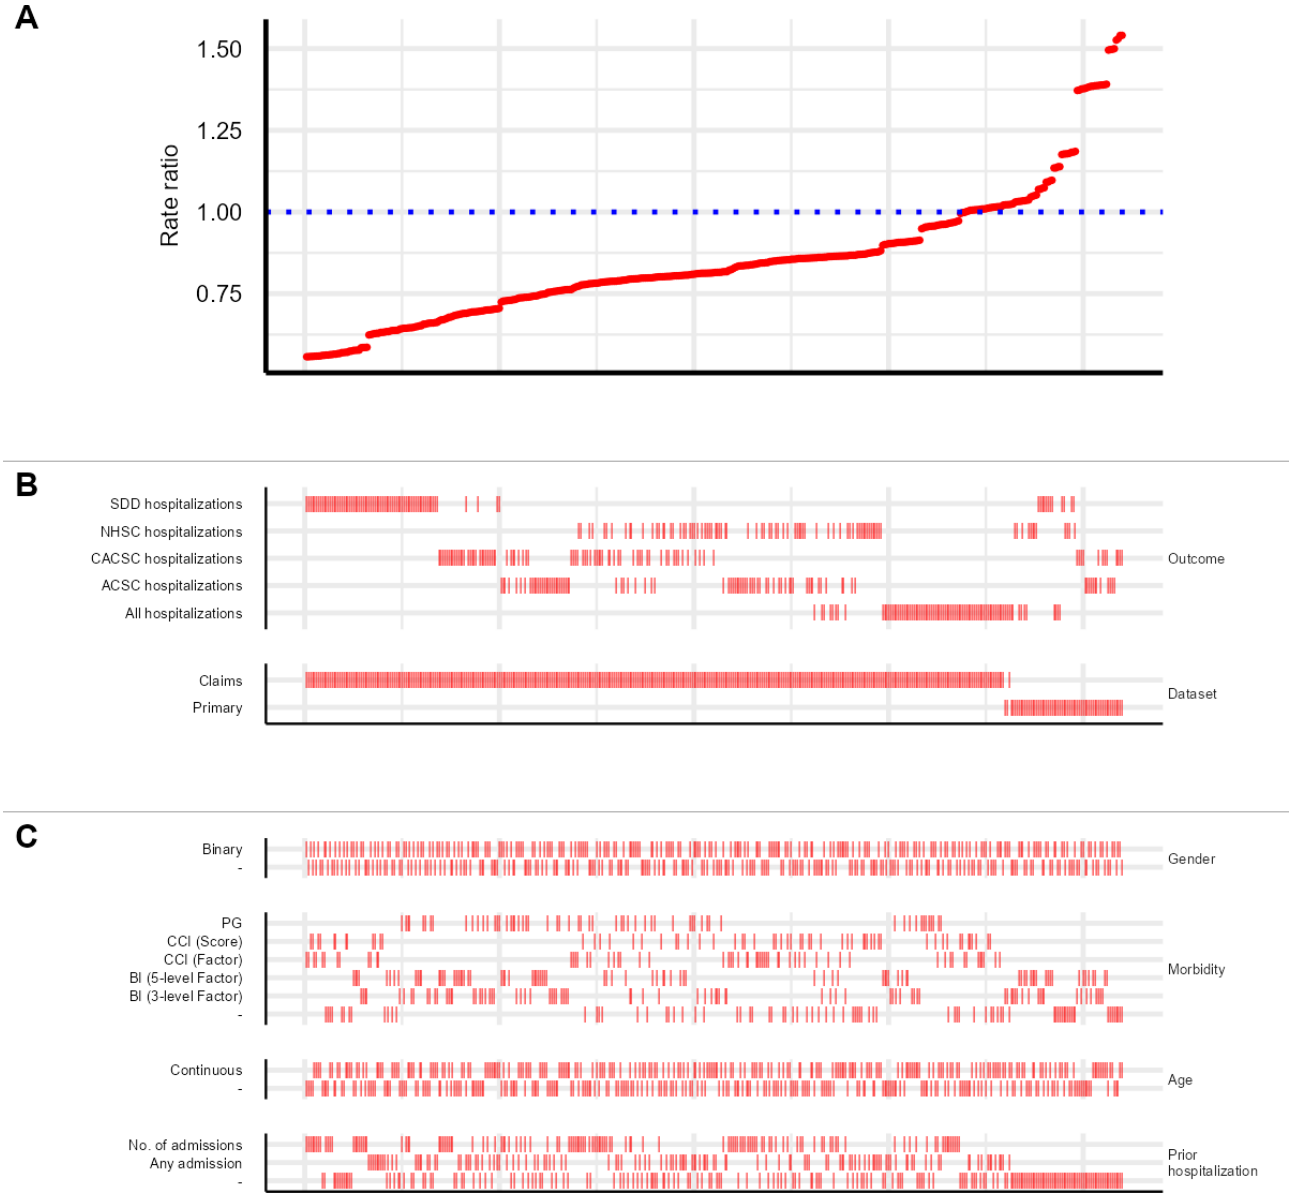
[d]NHSC: Nursing home-sensitive condition.

[e]SDD: Same-day discharges.

Modeling Approach 2: Count Models for Hospitalizations

For modeling approach 2, we ran a total of 420 count regression models with the number of hospitalizations as the response. Of these models, none failed to converge, leaving 420 models for analysis. Figure 4 shows the specification curve for these 420 model specifications.



The specification curve reveals that the choice of dataset and the operationalization of the outcome variable have the most noticeable influence on the size of the intervention effect. In particular, models using the primary dataset and SDD models had larger rate ratios than those using the claims dataset or other outcome operationalizations. Within the claims dataset, models using all hospitalizations as the outcome had larger rate ratios than those using other outcome operationalizations. The remaining model specification choices did not have as clear a systematic effect on the size of the intervention effect.

Table 6 shows the proportion of negative intervention effects, the mean, minimum, and maximum effect sizes as well as the median, minimum, and maximum *P* values for the 420 regression models: overall, by outcome variable, and by dataset. Over 80% (339/420) of regression models found a negative (ie, protective) intervention effect, with a mean rate ratio of 0.85. As for modeling approach 1, the intervention effect was nonsignificant for all 420 regression models, with a median *P* value of .42 (IQR .26-.57; although some SDD models exhibited *P* values as low as .08).

Models using all hospitalizations as the outcome had the lowest proportion of negative effects at 60.71% (51/84). Effect sizes (rate ratios) ranged from 0.56 to 1.54, with a mean rate ratio of 0.85. Table 6 also confirms the notable difference in the proportion of negative effects and mean rate ratio between the primary and the claims datasets.

Table . Effect direction, size, and significance for modeling approach 2 by outcome and dataset.

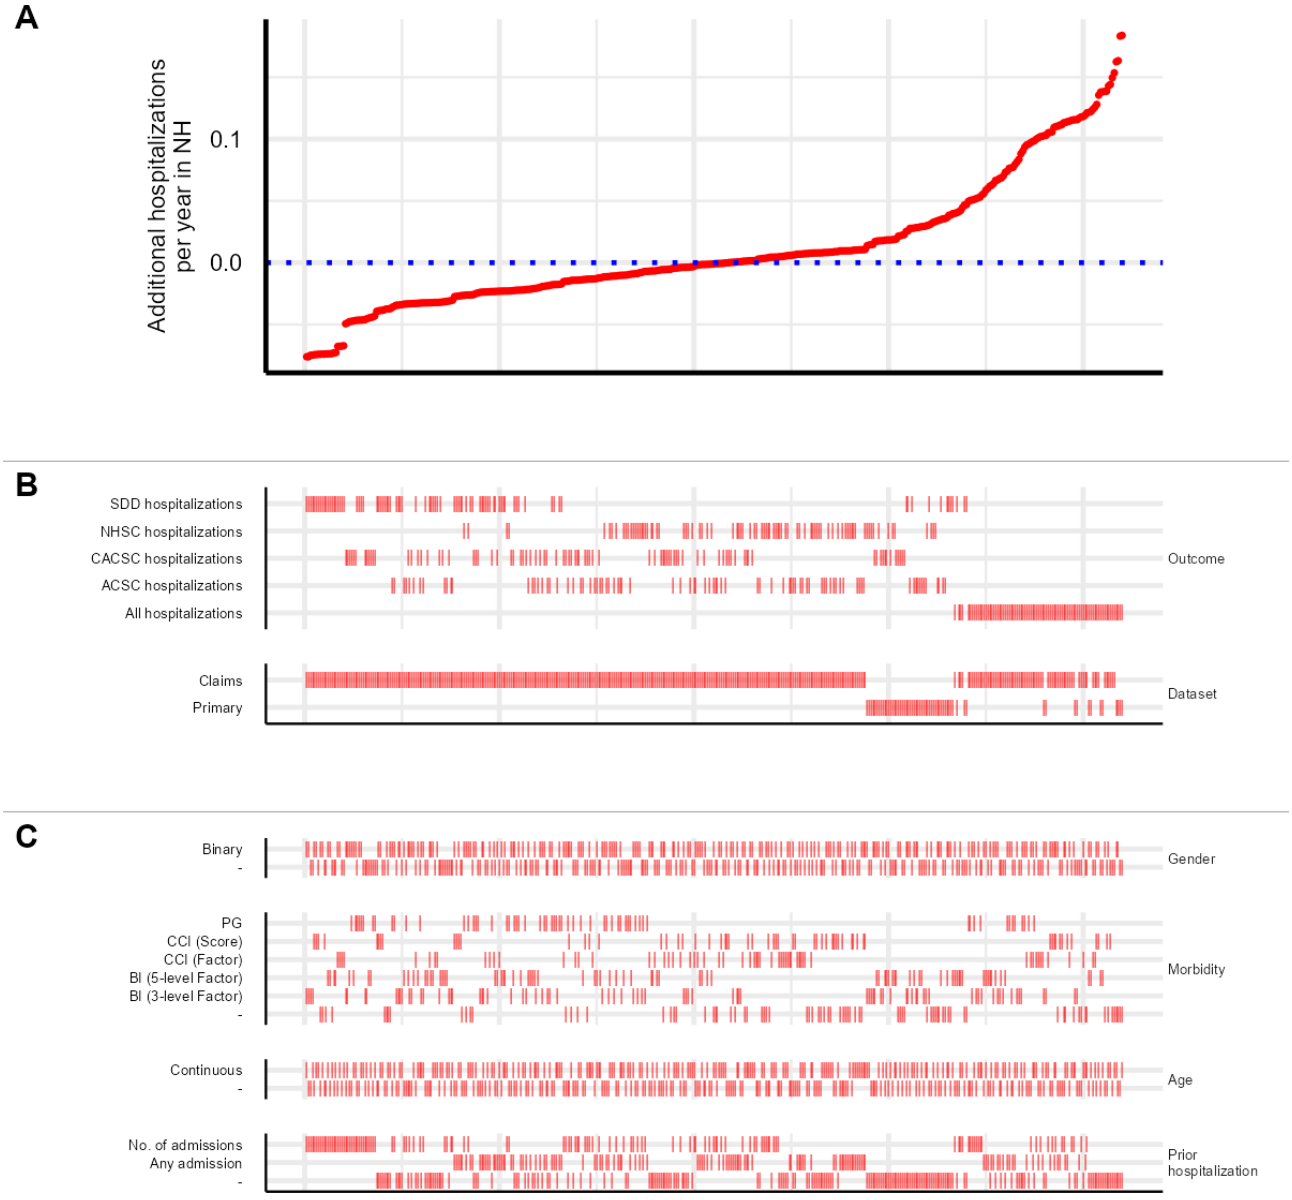
Outcome variable (days in hospital)	Negative effects	RR[a], mean (range)	*P* value, median (range)
Overall (N=420), n (%)	339 (80.71)	0.85 (0.56-1.54)	.42 (.08-.99)
By outcome (days in hospital) (n=84), n (%)			
All	51 (60.71)	0.97 (0.86-1.14)	.82 (.36-.99)
ACSC[b]	72 (85.71)	0.89 (0.72-1.50)	.40 (.12-.57)
CACSC[c]	72 (85.71)	0.84 (0.67-1.54)	.28 (.13-.42)
NHSC[d]	72 (85.71)	0.87 (0.77-1.19)	.51 (.39-.90)
SDD[e]	72 (85.71)	0.68 (0.56-1.18)	.20 (.08-.78)
By dataset, n (%)			
Primary (n=60)	0 (0.00)	1.22 (1.02-1.54)	.45 (.12-.90)
Claims (n=360)	339 (94.17)	0.79 (0.56-1.02)	.41 (.08-.99)

[a]RR: Relative risk.

[b]ACSC: Ambulatory care-sensitive condition.

[c]CACSC: Core ambulatory care-sensitive condition.

[d]NHSC: Nursing home-sensitive condition.



[e]SDD: Same-day discharges.

Modeling Approach 3: Binary Models for Hospitalization

For modeling approach 3, we ran a total of 420 binomial regression models with daily hospitalization as the (binary) response. Of these models, none failed to converge, leaving 420 models for analysis. Figure 5 shows the specification curve for these 420 model specifications.

XSL•FO
RenderX

Figure 5. Specification curve for modeling approach 3. SDD: same-day discharges; NHSC: nursing home-sensitive conditions; CACSC: core ambulatory care-sensitive conditions; ACSC: ambulatory care-sensitive conditions; PG: care grade (German: Pflegegrad); CCI: Charlson Comorbidity Index; BI: Barthel Index

As for modeling approach 2, the specification curve reveals that the choice of dataset and the operationalization of the outcome variable have the most noticeable influence on the size of the intervention effect. In particular, models using all hospitalizations had a larger number of additional hospitalizations per 365 days spent in the nursing home than those using other outcome operationalizations. Furthermore, among those models using outcome operationalizations other than all hospitalizations, those using the primary dataset had a larger number of additional hospitalizations per 365 days spent in the nursing home than those using the claims dataset. The remaining model specification choices did not have as clear a systematic effect on the size of the intervention effect.

Table 7 shows the proportion of negative intervention effects, the mean, minimum, and maximum effect sizes as well as the median, minimum, and maximum *P* values for the 420 regression models. Over half of the regression models (217/420, 51.67%) found a negative (ie, protective) intervention effect. Once again, the intervention effect was nonsignificant for all 420 regression models, with a median *P* value of .56 (IQR .28-.81; although some models exhibited *P* values as low as .07).

XSL•FO
RenderX

Table . Effect direction, size, and significance for modeling approach 3 by outcome and dataset.

Outcome variable (days in hospital)	Negative effects	Effect, mean (range)	*P* value, median (range)
Overall (N=420), n (%)	217 (51.67)	0.01 (–0.08 to 0.18)	.56 (.07->.99)
By outcome (days in hospital) (n=84), n (%)			
All	0 (0.00)	0.10 (0.04 to 0.18)	.37 (.07-.76)
ACSC[a]	48 (57.14)	0.00 (–0.04 to 0.04)	.78 (.09->.99)
CACSC[b]	65 (77.38)	–0.01 (–0.05 to 0.02)	.58 (.10->.99)
NHSC[c]	32 (38.10)	0.00 (–0.03 to 0.03)	.84 (.30-.99)
SDD[d]	72 (85.71)	–0.03 (–0.08 to 0.05)	.22 (.12-.62)
By dataset, n (%)			
Primary (n=60)	0 (0.00)	0.05 (0.01 to 0.18)	.26 (.07-.72)
Claims (n=360)	217 (60.28)	0.00 (–0.08 to 0.15)	.62 (.12->.99)

[a]ACSC: Ambulatory care-sensitive condition.

[b]CACSC: Core ambulatory care-sensitive condition.

[c]NHSC: Nursing home-sensitive condition.

[d]SDD: Same-day discharges.

Models with all hospitalizations as the outcome had the lowest proportion of negative effects, as all such models found a positive (ie, nonprotective) intervention effect. Effect sizes (the number of additional hospitalizations per 365 days spent in the nursing home) ranged from −0.08 to 0.18, with a mean of 0.01. This indicates that the absolute size of most intervention effects was not clinically relevant. As for modeling approach 2, zero of the 60 models on the primary dataset found a negative intervention effect, although the proportion of negative effects in the claims dataset was lower than for modeling approach 2.

Discussion

Principal Findings

We investigated the effect of an intersectoral telemedicine intervention on hospitalization probability for residents in nursing homes. Our analysis was based on data from a multicenter, prospective, cluster randomized controlled trial with an open cohort stepped wedge design. We conducted a specification curve analysis, for which we considered 1260 different regression model specifications, of which 1259 converged. Of these, none found a statistically significant (ie, $P<.05$) intervention effect.

While 854 of 1259 converged models found a (nonsignificant) negative intervention effect (67.83%), the distribution of these effects differed by modeling approach, choice of outcome, and dataset used. For modeling approaches 1 and 2 (count models for the number of hospital d and the number of hospitalizations at the patient-quarter level), more than 70% (298/419) and more than 80% (339/420) of the models found a negative (ie, protective) intervention effect, respectively. For modeling approach 3 (binary models for hospitalization probability at the patient-d level), only just over 50% (217/420) of models found a negative intervention effect. The differences in effect direction by choice of outcome and dataset were even more pronounced. While only 135 of 252 models using all hospitalizations (53.57%) and 116 of 252 NHSC models (46.03%) found a negative intervention effect, these proportions rose to 216 of 252 SDD models (85.71%) and 216 of 251 CACSC models (86.06%). And while almost three-quarters of models (807/1080) on the claims dataset found a negative intervention effect, only 26.26% (47/179) of models on the primary dataset did so.

Based on these results, our analysis does not support the hypothesis of a significant negative intervention effect. This may be due to either (1) issues with our data or methodology, (2) external factors such as the flood disaster and the COVID-19 pandemic, or (3) the actual noneffectiveness of the intervention.

Concerning (1), it could be argued that operationalizing the outcome using SDD or CACSC hospitalizations (where the proportion of negative intervention effects is also higher) may be more appropriate than using all hospitalizations, since the Optimal@NRW intervention specifically targeted potentially avoidable hospitalizations and included no mechanism to prevent necessary hospitalizations. Furthermore, the claims dataset contains more total ACSC and CACSC hospitalizations than the primary dataset, even though the primary dataset contains about 1.5 times as many patients and patient-days. This indicates that there may have been a data quality issue in the primary dataset (see limitations). Therefore, one could argue that using the claims dataset (where the proportion of negative intervention effects is also higher) is more appropriate than using the primary dataset.

Restricting the space of model specifications according to this line of argument can only increase the proportion of negative intervention effects. It does not change the fact that the intervention effect was nonsignificant in all models. However, since the sample size calculation was conducted for all hospitalizations (rather than one of the operationalizations of potentially avoidable hospitalizations), our study might not have

XSL•FO
RenderX

had a sufficient sample size to reliably detect intervention effects for potentially avoidable hospitalizations. This indicates that future studies explicitly focused on, and powered for the analysis of, potentially avoidable hospitalizations (and using high-quality datasets) may be better equipped to identify a (true) significant intervention effect.

Our results were also affected by the flood disaster and the COVID-19 pandemic (see limitations). These external factors directly impacted operations in the participating nursing homes, which might have affected the number of hospitalizations (and potentially avoidable hospitalizations, in particular). For instance, studies showed that there were fewer hospital admissions in general during the COVID-19 pandemic [13,14] in Germany. The potential impact of COVID-19 restrictions at the outset of our study may have led to more avoided hospitalizations compared to later phases, complicating the distinction between external influences and the intervention's true effect. This indicates that future studies conducted without the influence of these external factors may reach a different result than our analysis.

However, the possibility remains that our results reflect the true noneffectiveness of the intervention. This would be surprising, as several international studies have demonstrated an effect of telemedicine in nursing homes reducing hospital admissions (particularly emergency admissions) [40,41]. For instance, Joseph et al (2020) [41] found that NHR receiving telemedicine in acute care situations were less likely to be transferred to emergency departments than a control group.

In Germany, a number of pilot projects [42,43] have emerged that align with our objectives by integrating telemedicine solutions to enhance acute care management in order to reduce potentially avoidable hospitalizations. A previous study, conducted in the same region as the Optimal@NRW project, evaluated a tele-emergency medical service, in which a remote emergency physician supported paramedics to reduce the need for on-site physician involvement [42]. In a randomized controlled trial, the researchers demonstrated that 58% of patients in the intervention group could be dispatched solely by paramedics, compared to only 6% in the control group. This finding underlines the feasibility and suitability of telemedicine approaches in acute care situations and highlights that the successful implementation of telemedicine approaches requires a significant adaptation period before reaching full operational efficiency [42]. The nursing homes in our study exhibited an increasing use of teleconsultations over time. It therefore remains questionable for our study whether an intervention phase of 6 to 15 months was sufficient to fully realize the intervention's potential and achieve sustained effectiveness. Moreover, our intervention did not focus exclusively on a telemedicine approach for acute care situations but also integrated mobile nonphysician medical assistants, whom telephysicians could dispatch to expand the range of on-site treatments in nursing homes. Previous pilot studies have applied similar approaches, such as the community paramedic system (Gemeindenotfallsanitäter), which aimed to provide on-site medical assessment and care for low-acuity emergencies. Studying the Gemeindenotfallsanitäter, Seeger et al [43] demonstrated that 60% of NHR were treated on-site. While they concluded that Gemeindenotfallsanitäter saves resources of emergency services and hospitals, it is essential to note that their study primarily focused on process outcomes rather than quantifying patient-relevant clinical endpoints, as we did.

Successful implementation of telemedicine and complex interventions also strongly depends on the motivation of affected staff. Alongside our study, we systematically monitored the acceptance of participating nursing staff to gain deeper insights into the dynamics, facilitators, and barriers influencing the effective implementation of our intervention. While the results, which have been published elsewhere [44], suggested increased telemedicine acceptance during the intervention phase, these differences did not reach statistical significance. This underlines the need for an extended implementation period to foster greater acceptance over time. The numbers of teleconsultations also differed greatly between nursing homes, in that 15 nursing homes used 75% of all teleconsultations. This cannot be purely attributed to less acute care situations, but also to nursing home specific reasons, which require further research.

Rather than focusing purely on telemedicine to enhance acute care situations, we advocate for a holistic, intersectoral approach that extends beyond merely addressing acute medical needs at the point of care. Therefore, for the Optimal@NRW intervention, we chose a comprehensive approach that integrates preventive measures via our Frühwarnsystem to identify potential health risks in advance and incorporates a follow-up strategy through mobile nonphysician medical assistants to enhance on-site treatment opportunities. However, implementing multiple inherently complex components at once may overwhelm practical application due to staff shortages and workload consolidation in the German health care system. For instance, the Frühwarnsystem measurement was intended to be conducted daily by the nursing staff, but proved to be impractical. Instead, simpler and more manageable solutions are needed, such as implementing wearable technology for NHR, which does not require additional staff resources [45].

We also anticipated incorporating an intersectoral approach by engaging various stakeholders involved in acute care situations, particularly GPs. Recent qualitative and quantitative research in the German nursing sector indicates that including GPs in telemedical and digital interventions for NHR should increase access to GPs outside regular consultation hours, save time, and ease the workload of communicating with GPs for nursing home staff [46,47]. Meanwhile, initial evidence from pilot and pre-post intervention studies in Germany suggests that GP-based telemedicine interventions for NHR can reduce avoidable hospitalizations [48,49], although more evidence from high-quality randomized control trials is needed. Telemedicine interventions for NHR have also been found to reduce avoidable hospitalizations in other contexts, including France [50,51] and the United States [52].

However, during our study, we realized that including GPs proved particularly challenging, with only a very limited number ultimately participating. We invested significant time and effort into personal outreach (such as phone calls and meetings) and provided financial incentives; however, these efforts proved ineffective at recruiting GPs. Given the critical role of GPs in

XSL•FO
RenderX

coordinating and providing medical care for NHR, their inclusion in future intersectoral interventions is essential. This underscores the need for a more effective outreach strategy to enhance GP engagement and facilitate their integration into telemedicine-based acute care models.

Strengths and Limitations

To our knowledge, this is the first study evaluating a comprehensive telemedicine-based approach to treat acute care situations of NHR in Germany regarding patient-relevant clinical outcomes. The main strength of our research is the use of specification curve analysis, which allowed us to investigate the impact of different modeling choices on the direction, size, and significance of the intervention effect. It ensures the robustness of the presented results.

A methodological limitation of our approach is that our specification curve analysis is mainly descriptive. Inferential specification curve analysis is also possible and even recommended in the literature, with Simonsohn et al (2020) suggesting test statistics that include the median effect across all specifications (in our case, 0.11 additional hospitalizations per y for an average participant) and the share of specifications with significant effects in the predicted direction (in our case, none) [33]. To obtain the distributions of these test statistics, they propose modifying the data by shuffling the columns containing randomly assigned variables. For this shuffled dataset, the null hypothesis is now known to be true. Calculating the test statistic of interest for hundreds of random samples from the modified dataset then delivers the estimated distribution of the test statistic under the null hypothesis [33].

In this paper, we did not undertake an inferential specification curve analysis. This was mainly due to the structure of our data. Each row in our datasets represented a patient-day. The assignment of these patient-days to a treatment phase (intervention or control) depends on the date of the patient-day and the nursing home in which the patient was recruited. Therefore, shuffling the treatment column as described above would be inappropriate. Furthermore, even if a suitably shuffled dataset could be created, fitting 1260 mixed-effects regression models for hundreds of samples would have exceeded available computational resources. However, the lack of an inferential specification curve analysis does not represent an overly significant limitation of our results, as all intervention effects were nonsignificant.

Although the primary data was continuously checked for plausibility by a data monitoring team throughout the study, it can be assumed that there are inconsistencies in the primary dataset due to the self-documentation process and an initially paper-based procedure. This became particularly evident when compared with the SHI claims data where, for example, the number of ACSC hospitalizations per patient-year was approximately twice as high in the claims dataset as in the primary dataset. Such inconsistencies raise concerns about the internal validity of the primary dataset. Moreover, models using the (quality-assured) claims data exhibited a notably higher proportion of negative intervention effects. However, this finding must be interpreted with caution, as the smaller sample size in the claims dataset may introduce bias, potentially overestimating the observed intervention effects even though no model showed significant results. It must also be noted that relevant confounders of morbidity included in our regression models were either not captured in the primary dataset (eg, care grade) or could only be applied for a subsample of included NHR due to missing data (eg, BI).

Another limitation of this study is the assumed effect size of a 30% reduction in hospital days during the intervention phase, which served as the basis for the sample size calculation. In retrospect, this estimate appears overly optimistic, potentially leading to an underpowered study design. Furthermore, the heterogeneous utilization of intervention components across different nursing homes may have contributed to variations in the intervention's effectiveness, further complicating the ability to detect a statistically significant effect. This variability, combined with the potential underestimation of the required sample size, likely impacted the study's ability to demonstrate a significant effect, particularly when considering general hospitalization outcomes rather than specific, targeted endpoints.

Accordingly, future studies should base their sample size calculations on small-to-moderate effect sizes. Although this would increase the sample size needed, larger sample sizes may be more feasible in future projects using only claims data, since researchers would not need to collect primary data for each participant. This may also reduce dropout rates, keeping the total sample size needed manageable. Furthermore, future studies may be able to shorten the transition phase (in which participants are recruited and data is collected, but not analyzed), which would further reduce the total sample size needed. Finally, using only claims data, rather than both primary and claims data, may alleviate the concerns regarding primary data quality outlined above.

Beyond these methodological concerns, our study faced several external limitations that may have affected our data and results. A significant portion of the data collection period was impacted by the COVID-19 pandemic and the June 2021 flood disaster. These events affected participant numbers, the feasibility of the study, and data collection processes, while also influencing the analysis, as they could not be directly accounted for. Such unforeseen events may limit the generalizability of our findings.

Conclusion

Based on the results of our specification curve analysis, we conclude that the Optimal@NRW intervention had no significant effect on hospitalization probability for NHR. This could be attributed either to (1) methodological limitations of our study and analysis, (2) external factors, such as the flood disaster and COVID-19 pandemic, or (3) the actual noneffectiveness of the intervention. To address (1), future research should choose more targeted outcomes measuring potentially avoidable hospitalizations, such as SDD or CACSC, which align more closely with the intended underlying mechanisms of the intervention. To address (3), holistic, intersectoral, telemedicine-based interventions should prioritize optimizing usability for intervention components to ensure seamless integration into existing workflows, while minimizing additional workload for nursing staff. Moreover, future studies could benefit from the progressive scalability of telemedicine-based

XSL•FO
RenderX

treatments, leveraging potential upscaling scenarios that enhance both feasibility and efficiency. As familiarity and confidence in telemedicine approaches continue to grow, particularly in acute care settings, increasing trust in digital health care solutions may further strengthen their impact on patient-relevant endpoints, and long-term sustainability.

Abstract

Background: Rapid population aging and a worsening shortage of care workers necessitate the identification of older adults who require proactive interventions. Although machine learning (ML) has been increasingly applied in gerontology, existing studies have predominantly focused on social isolation, loneliness, depression, falls, and frailty in isolation rather than on the integrated construct of care needs.

Objective: This study aimed to develop and interpret an explainable ML model that identifies care needs in community-dwelling Korean older adults. Beyond physical health indicators such as disease and functional status, this study adopted a comprehensive approach that included mental health, cognitive function, health behaviors, and socioenvironmental determinants, such as social participation, social support, and the housing environment, to present an integrated model encompassing both health and social care needs.

Methods: Data were obtained from the 2023 Korea Senior Survey, a nationally representative sample of 10,078 community-dwelling adults aged 60 years and older. The data were split 70:30 into training (n=7054) and held-out test (n=3024) sets. Seven algorithms were compared (logistic regression, decision tree, support vector machine, random forest, gradient-boosted decision trees, extreme gradient boosting, and light gradient boosting machine) using stratified 5-fold cross-validation on the training set. Discrimination was assessed by the area under the receiver operating characteristic curve (AUC). Model interpretability used Shapley additive explanations with bootstrap stability assessment across folds.

Results: Model A (excluding activities of daily living or instrumental activities of daily living [IADL]) achieved good discrimination (AUC 0.892, 95% CI 0.866 - 0.918), adequate calibration (calibration slope=0.826), and positive clinical net benefit, demonstrating that upstream factors alone can identify older adults with care needs without relying on functional status. Shapley additive explanations analysis identified age, nutritional risk, employment status, depressive symptoms, self-rated health, cognitive function, household income, and home modification as the leading predictors, with high rank stability across cross-validation folds. Model B (including activities of daily living or IADL) yielded a higher AUC (0.976, 95% CI 0.962 - 0.989), but this reflected the near-tautological relationship between IADL and self-reported care needs rather than genuine upstream predictive value. Using an objective composite outcome yielded equivalent discrimination (AUC 0.892), supporting robustness to the outcome definition.

Conclusions: Explainable ML models offer high predictive accuracy and strong interpretability for identifying care needs among older adults. Care needs in community-dwelling Korean older adults can be identified with good discrimination, calibration, and clinical net benefit using multidimensional nonfunctional factors alone. By highlighting the significant roles of health, social, and environmental factors, this study provides empirical evidence to support evidence-based decision-making for the Long-Term Care Insurance system and integrated community care policies.

Introduction

The intersection of rapid demographic aging and a shrinking care workforce in South Korea creates an urgent need to identify older adults who currently require care or are at elevated risk. In response to these demographic changes, South Korea introduced the Long-Term Care Insurance (LTCI) system in 2008. As shortages in the care workforce intensify, the Korean government is preparing to implement the Act on Integrated Support for Community Care (Integrated Community Care Act) in 2026. These policy initiatives aim to provide a comprehensive range of services, from mild support to intensive care, enabling older adults to maintain their lives within their communities. With the enactment of this legislation, it is essential to predict care needs across multiple dimensions; however, current eligibility assessments predominantly rely on functional status, such as activities of daily living (ADL). To effectively implement integrated care across the continuum from mild to severe needs, it is necessary to move beyond simple functional assessments and analyze predictive factors from a multidimensional perspective using big data.

Although machine learning (ML) has been increasingly applied in gerontology to address these complexities, existing studies have tended to be thematic rather than holistic. Research in this field has predominantly focused on social isolation and loneliness. For instance, ML has been used to predict social isolation among older adults in China [1] and sleep disorders among older adults with multimorbidity [2]. Similarly, domestic research in Korea has largely focused on specific geriatric syndromes, such as depression [3,4] and fall risk [5]. While valuable, these studies address isolated aspects of aging rather than the comprehensive demand for care. Recent applications of explainable ML to other geriatric outcomes have included cognitive decline [6] and frailty classification [7] in community-dwelling older adults, but none have focused on the integrated construct of care needs.

Research specifically predicting the care needs of older adults remains limited. Few studies have been conducted to predict care needs in Japan [8] and Korea [9] using public insurance claims data. However, these studies are limited by their reliance on administrative data, including medical history, health care, and long-term care service usage records, and do not consider sociodemographic and environmental factors that significantly influence individual care needs. Moreover, some studies have predicted physical disability based on ADL and instrumental activities of daily living (IADL) scores [10], as well as frailty [11]. A conceptual gap exists between functional disability, which is generally defined as a clinical measure, and perceived care needs, which are defined as a subjective demand for assistance [12].

Although the volume of multidimensional ML research in gerontology is expanding, there is a notable absence of studies applying these techniques to predict comprehensive care needs among older Korean adults using survey data. To address this gap, this study has 2 objectives. The first is to develop and interpret an explainable ML model that identifies community-dwelling older adults with care needs using multidimensional upstream factors alone, excluding functional status (ADL and IADL). The second is to characterize the relative contribution of predictors across demographic, health, behavioral, psychological, cognitive, socioeconomic, social support, and environmental domains, thereby examining whether care needs behave as a multidimensional construct. This study aims to provide a robust evidence base for the successful implementation of upcoming integrated care policies.

Methods

Data Source and Participants

This study used data from the 2023 Korea Senior Survey, a nationally representative survey initiated in 2007, to examine the characteristics of older adults in Korea. This survey collects comprehensive information across multiple domains, including health status, economic conditions, and social participation, and enables monitoring of changes over time.

A total of 10,078 community-dwelling adults aged 60 years and older were included in this analysis. Data on demographic, health-related, functional, and psychosocial characteristics were extracted for this study. Outcome prevalence was 8.7% (875/10,078, 95% CI 8.1% - 9.3%), giving an imbalance ratio of approximately 1:10.5.

Missingness was very low across the candidate predictor set (median 0.0%, IQR 0.0% - 0.0% per variable; range 0.0% - 10.6%). Two variables exceeding the prespecified 10% threshold, frequency of contact with children and frequency of contact with friends, were excluded a priori. Continuous variables were imputed using the median and categorical variables using the mode, with imputation parameters fitted only on the training fold and applied to held-out folds to prevent leakage. A complete-case sensitivity analysis yielded substantively identical results.

This study was reported in accordance with the TRIPOD+AI (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis+AI) statement [13]. The completed checklist is provided in Checklist 1.

Ethical Considerations

The sampling design and survey content of the 2023 National Survey of Older Koreans were officially approved by Statistics Korea (National Statistics Approval Number 117071). The study protocol was reviewed and approved by the Institutional Review Board of the Korea Institute for Health and Social Affairs (2023 - 078).

Measures

In this study, care needs were assessed using a self-reported questionnaire. Participants were asked whether they required assistance or care in their daily lives. Responses were dichotomized to define the outcome variable. Participants who reported requiring care were classified as the care-needs group and assigned a value of 1, whereas those who reported not requiring care were classified as the no–care-needs group and assigned a value of 0.

XSL•FO
RenderX

Based on previous studies and established theoretical frameworks on care needs among older adults, a comprehensive set of multidimensional predictive variables was selected. Demographic characteristics included gender, age, marital status (spouse), educational attainment, current employment status, number of household members, and household income. Subjective health variables comprised self-rated health and spouse's self-rated health. Physical health-related variables included the number of chronic conditions, BMI, sleep quality, and history of falls. Health behavior variables included current smoking status, current drinking status, and regular exercise. Nutritional health was assessed using nutritional risk indicators, including nutritional risk status and the total Nutritional Screening Initiative (NSI) score.

Health care utilization variables included outpatient or hospital visits and health-screening experience within the past 2 years. Mental and cognitive status was measured using depressive symptoms and cognitive function. Functional status was evaluated using ADL and IADL total scores. Binary limitation indicators were excluded from the candidate predictor set to avoid redundancy with the continuous totals. Social participation variables encompassed participation in leisure activities, educational activities, hobby clubs, social groups, political groups, volunteer activities, religious affiliations, and the use of senior welfare centers. Social support was assessed based on the number of available supporters when feeling depressed, when ill, or when needing to borrow money. Finally, living environment factors included housing satisfaction, home modification level, and area of residence.

Composite social-contact indices that overlapped with the outcome construct were excluded a priori as leakage candidates. From the 87 original variables, 6 were excluded a priori: 2 due to high missingness (more than 10%), 2 as redundant binary indicators of functional limitations, and 2 as leakage candidates. This yielded 81 final candidate predictors—79 were used in model A (excluding ADL and IADL totals) and 81 in model B.

Analytical Strategy

Two prespecified models were compared. Model A (primary, upstream) included all 79 candidate predictors except the ADL and IADL totals. This model targets the practical task of identifying older adults at risk before functional dependence is established, the relevant operating point for preventive screening under the Integrated Community Care Act. Model B (benchmark, full) included all 81 candidate predictors and is reported only as a benchmark to characterize the upper bound of predictive performance when functional status is observable.

The analytical process for both models proceeded through descriptive analysis, predictive modeling, feature selection, class-imbalance handling, hyperparameter specification, validation, calibration and decision-curve analysis, model interpretation, and sensitivity analyses.

First, descriptive analyses were conducted to compare the baseline characteristics of older adults with and without care needs. Independent-sample *2-tailed t* tests were used for continuous variables, and chi-square tests were applied for categorical variables.

Second, for predictive modeling, the dataset containing 10,078 samples was split 70:30 (stratified by outcome) into a training set (prevalence, 612/7054, 8.7%) and a held-out test set (prevalence, 263/3024, 8.7%). Seven ML algorithms were compared: logistic regression (LR), decision tree (DT), support vector machine (SVM), random forest (RF), gradient-boosted decision trees (GBDT), extreme gradient boosting (XGBoost), and light gradient boosting machine (LightGBM).

Third, all candidate predictors were retained for model fitting; built-in regularization within each algorithm provided implicit feature weighting (L2 penalty for LR, tree-based split importance for RF and gradient-boosted models, a radial basis function kernel with C=1.0 for SVM, and depth-limited splits for the DT). To address potential redundancy across the candidate set, post hoc Shapley additive explanation (SHAP)-based feature ranking with bootstrap-based stability assessment across cross-validation folds (Jaccard similarity of the top-10 set) was used to characterize the relative contribution of individual predictors (Multimedia Appendix 1).

Fourth, the class imbalance (1:10.5) was handled using 2 complementary approaches. For boosted models (XGBoost, LightGBM, and GBDT), a class-weighted loss function was used, with the positive class weighted by the inverse of its frequency. For nonboosted models, the synthetic minority oversampling technique [14] was applied only within each cross-validation training fold, never on validation or test partitions, to prevent information leakage. LR and SVM models were additionally fitted with class-balanced weights as a robustness check.

Fifth, hyperparameters were prespecified for each algorithm based on values commonly used in the ML literature for moderately sized clinical datasets; no algorithm-specific hyperparameter optimization was performed (XGBoost: 400 estimators, learning rate 0.05, max depth 4, subsample 0.8, colsample_bytree 0.8; LightGBM: 400 estimators, learning rate 0.05, max depth 6, num_leaves 31; GBDT: 300 estimators, learning rate 0.05, max depth 3; RF: 500 trees, min_samples_leaf 2; LR: L2 penalty with C=1.0; decision tree: max depth 6, min_samples_leaf 20; SVM: RBF kernel with C=1.0). Boosted models used positive-class scale weights computed from each training fold; nonboosted models used class-balanced weights (with synthetic minority oversampling technique applied within the cross-validation training fold for nonboosted models). The random seed was set to 42 for reproducibility. All analyses were conducted in Python 3 on Google Colab using *scikit-learn*, *statsmodels*, *SciPy*, *LightGBM*, *XGBoost*, *imbalanced-learn*, and *SHAP*.

Sixth, the validation strategy combined stratified 5-fold cross-validation on the training portion (with the mean, SD across folds reported as the primary performance estimate) with a final evaluation on the held-out test set. Discrimination was assessed using the area under the receiver operating characteristic curve (AUC), with 95% CIs from the DeLong method on the test fold and from 1000 bootstrap resamples. Additional metrics included the precision-recall AUC (PR-AUC), the prevalence-adjusted relative PR-AUC (PR-AUC ÷ outcome prevalence), sensitivity, specificity, the F_1-score,

XSL•FO
RenderX

and the Matthews correlation coefficient (MCC). Performance was reported at 3 operating thresholds, the default of 0.5, prevalence-matched (0.087), and Youden-optimal, to demonstrate the sensitivity-specificity trade-off across the relevant decision range.

Seventh, calibration was assessed on the held-out test set using the Brier score, calibration slope and intercept, and reliability diagrams in which predicted probabilities were grouped into 10 quantile-based bins. Predicted probabilities were post hoc recalibrated using isotonic regression fitted on the training portion via 5-fold cross-validated stacking. Decision-curve analysis was performed across threshold probabilities ranging from 1% to 50% [15] to assess clinical net benefit relative to the "treat all" and "treat none" reference strategies.

Eighth, model interpretability was assessed using SHAP [16]. SHAP values were computed within each of the 5 cross-validation folds, and the mean |SHAP| values were computed with bootstrap-derived 95% CIs, together with the rank stability of the top-10 features quantified by the Jaccard similarity index across folds (Multimedia Appendix 1).

Finally, prespecified sensitivity analyses included leave-one-feature-out for the top-10 predictors of model A; an alternative outcome operationalization using an objective composite (2 or more IADL limitations and/or 1 or more ADL limitations; prevalence, 1411/10,078, 14.0%); stratification of performance by depressive-symptom quartile; and complete-case analysis. Discrimination was preserved across Center for Epidemiologic Studies Depression Scale–Short Form (CES-D-SF) score quartiles (AUC range 0.86‐0.91), arguing against differential model performance driven by depression-related self-report bias. Complete-case analysis yielded substantively identical results.

Results

Sample Characteristics

Table 1 presents the baseline characteristics of older adults according to the care-needs status. Compared with older adults without care needs, those with care needs were significantly older and more likely to be female older adults. They were also less likely to have a spouse and had substantially lower levels of educational attainment and employment participation. Household income was significantly lower in the care-needs group, whereas the number of household members did not differ significantly between the 2 groups. Regarding health status, older adults with care needs reported poorer self-rated health and poorer spouse's self-rated health, and they had a significantly higher number of chronic conditions. BMI was slightly lower in the care-needs group. Regarding social resources, the care-needs group had fewer available supporters when feeling depressed, when ill, or when needing to borrow money, indicating lower levels of social support.

[a]Monthly household income was measured at KR ₩10,000=US $7.67 as of November 10, 2023.

[b]NSI: Nutritional Screening Initiative.

[c]ADL: activities of daily living.

[d]IADL: instrumental activities of daily living.

Variable Diagnostics

Variance inflation factors (VIFs) were computed for all numeric predictors in model A. The highest VIF was 2.31 (number of available supporters when ill), well below the conventional concerning threshold of 5 and even below the conservative threshold of 2.5. The 7 highest-VIF variables (all VIFs<2.5) reflect expected modest correlations among related health and social-support constructs, but each carries sufficient independent information to be retained. No predictor required removal on multicollinearity grounds.

Multivariable LR

As a confirmatory descriptive complement to the ML analyses, Table 2 presents the results of the multivariable LR analysis identifying independent factors associated with care needs among older adults.

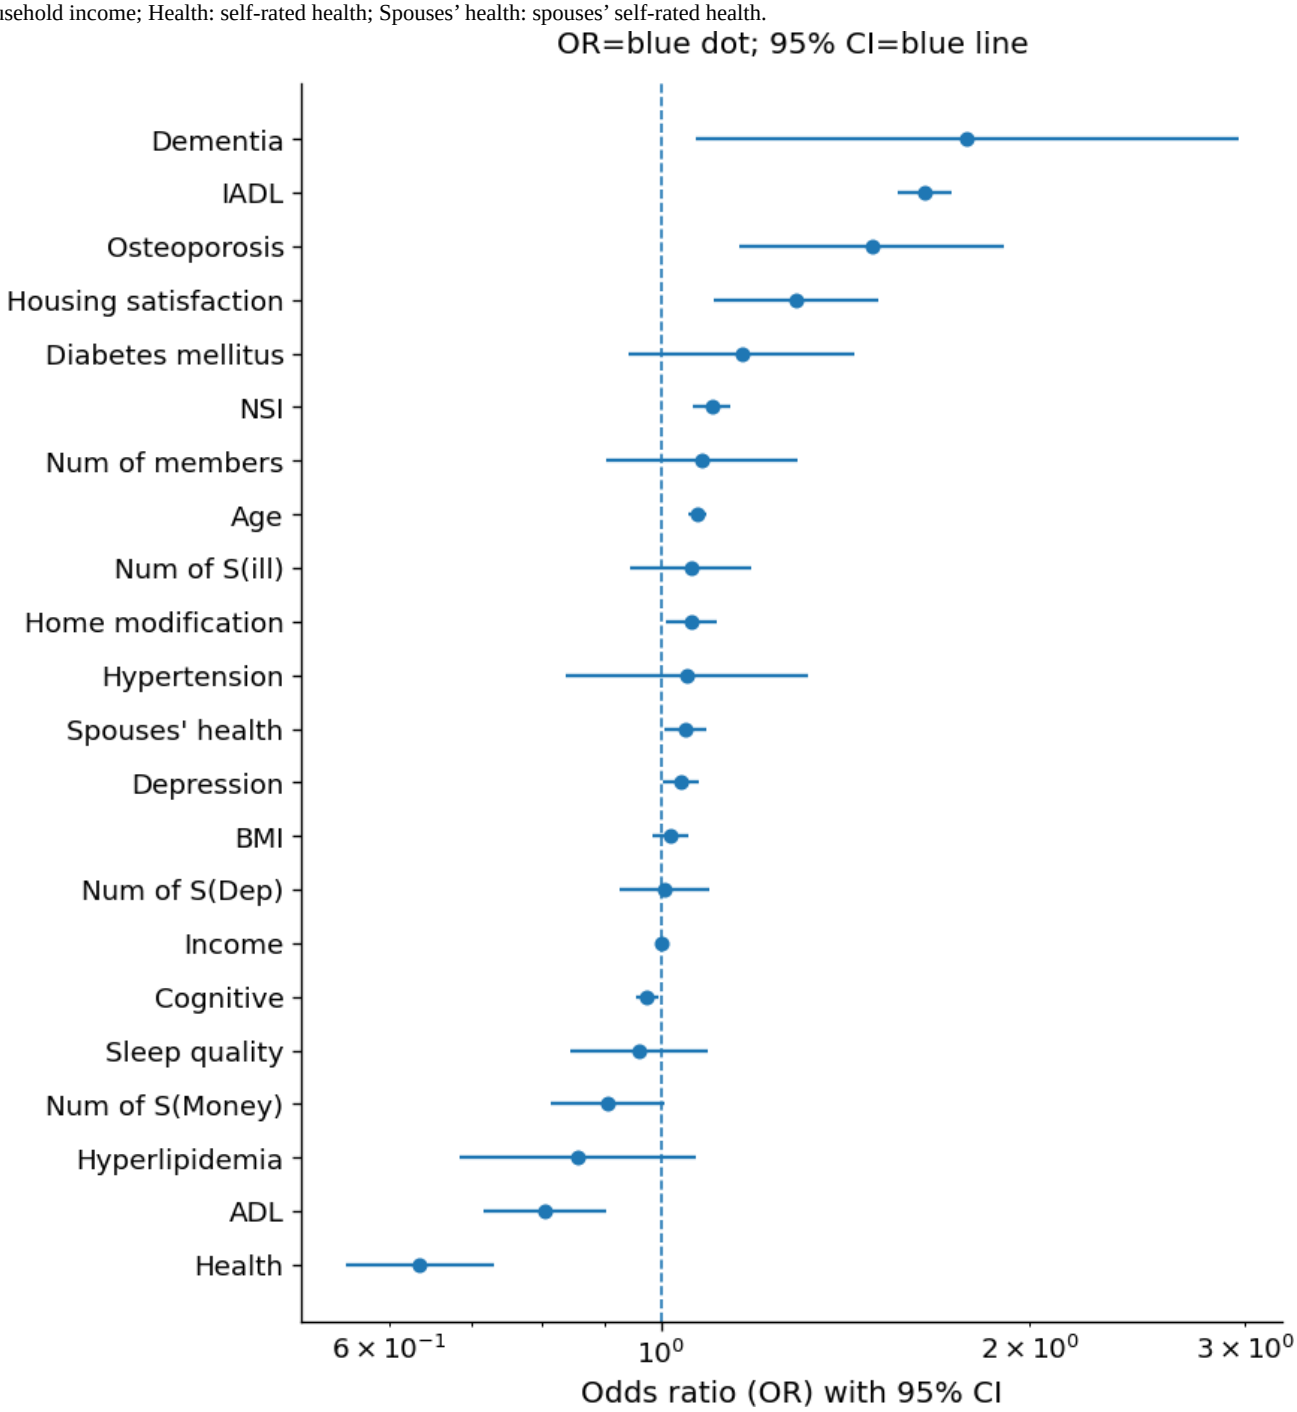
[b]β: regression coefficient.

[c]OR: odds ratio.

Older age was significantly associated with higher odds of care needs, indicating an increased likelihood of requiring care with advancing age. In contrast, better self-rated health was associated with lower odds of care needs, suggesting a protective effect. Regarding health-related factors, spouse's poor self-rated health, osteoporosis, and dementia were significantly associated with increased odds of care needs. Additionally, higher nutritional risk scores and greater depressive symptoms were positively associated with care needs, indicating that nutritional vulnerability and mental health status play important roles.



Functional status showed strong and distinct associations. Greater limitations in IADL were associated with higher odds of care needs, whereas better performance in basic ADL was associated with lower odds. Higher cognitive function scores were also inversely associated with care needs. Regarding the residential environment, higher housing satisfaction and home modifications were significantly associated with increased odds of care needs, suggesting that housing conditions and environmental adaptations reflect underlying care demands.

Overall, care needs among older adults were independently associated with advanced age, poor health and nutritional status, mental and cognitive vulnerability, functional impairment, and housing-related factors.

Figure 1 visually summarizes the adjusted odds ratios and 95% CIs from the final multivariable LR model. The vertical dashed line indicates an odds ratio of 1.0, representing a null association. This demonstrates that the determinants of care needs vary substantially in magnitude, underscoring the heterogeneous contributions of functional, health-related, and environmental factors within the multivariable model.

Figure 1. Various factors are associated with the specific care needs of the population. ADL: activities of daily living; IADL: instrumental activities of daily living; NSI: Nutritional Screening Initiative total score; Num of members: number of household members; Num of S(Dep): number of supporters when feeling depressed; Num of S(ill): number of supporters when ill; Num of S(Money): number of supporters to borrow money from; Income: household income; Health: self-rated health; Spouses' health: spouses' self-rated health.

Model Performance

Cross-validated performance (5-fold stratified on the training set) is shown in Table 3. GBDT achieved the highest AUC (mean 0.913, SD 0.007), narrowly ahead of XGBoost (mean 0.909, SD 0.010) and RF (mean 0.907, SD 0.007). All 7 algorithms achieved an AUC of more than 0.85 in model A, indicating that the upstream signal is robust to algorithm choice and not dependent on any single inductive bias.

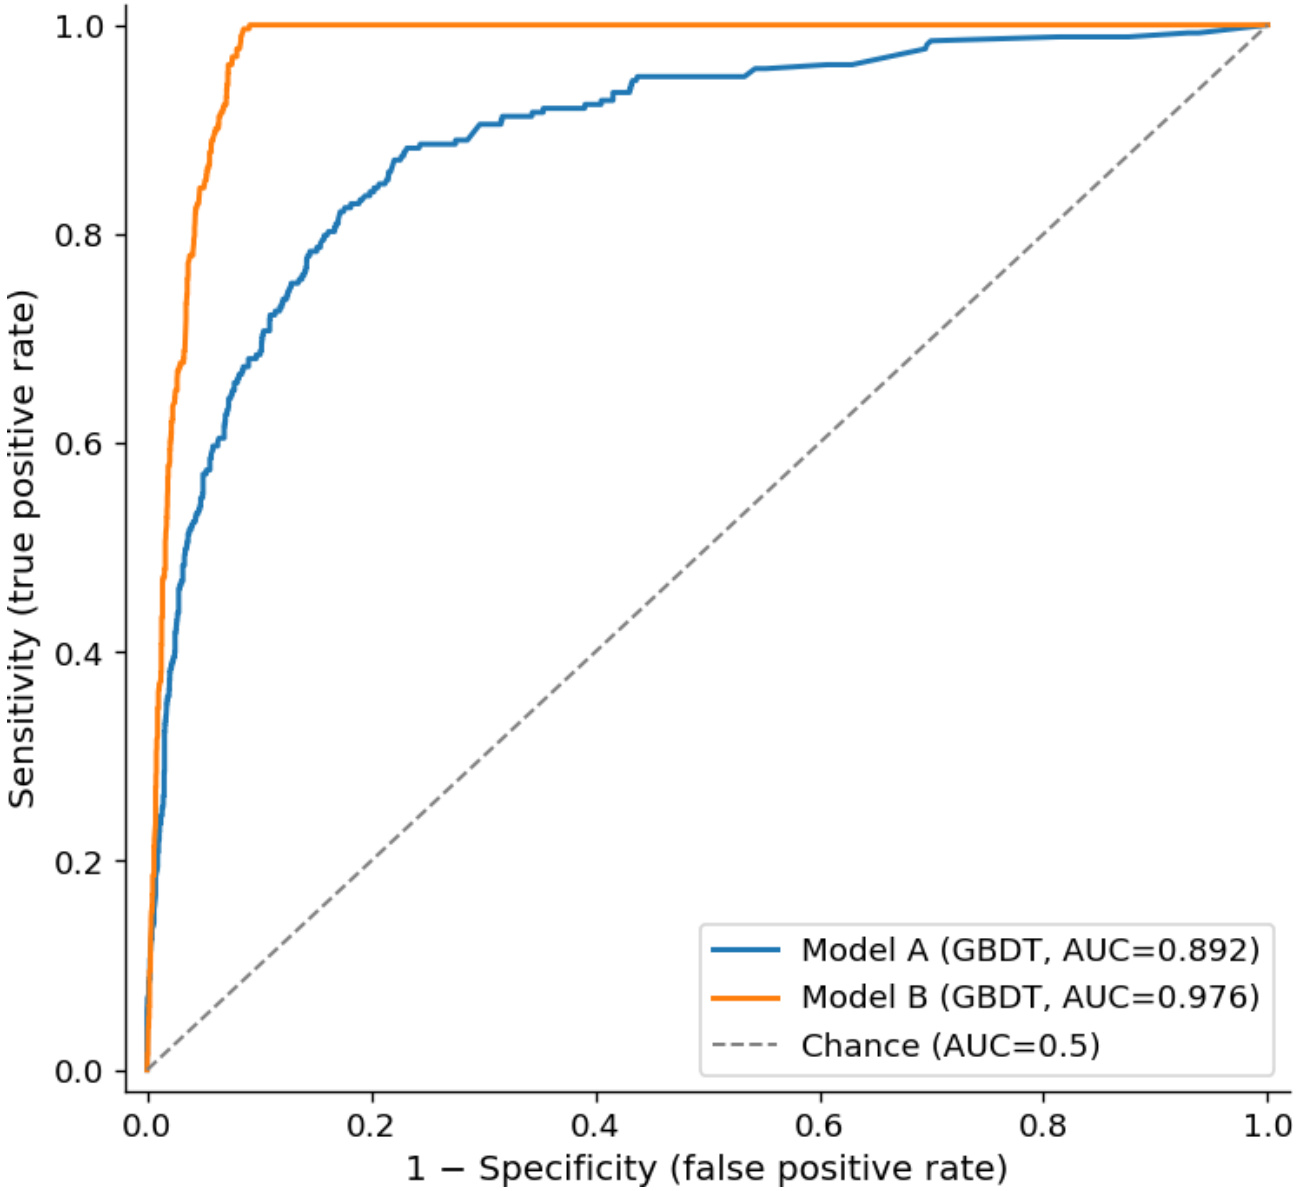
[e]Not applicable.

[f]LightGBM: light gradient boosting machine.

[g]SVM: support vector machine.



On the held-out test set (n=3024), GBDT (model A) achieved an AUC of 0.892 (95% CI 0.866 - 0.918, DeLong method; bootstrap 95% CI 0.870 - 0.912), with a PR-AUC of 0.530 (6.10 × the no-skill baseline of 0.087). At the Youden-optimal threshold (0.077), sensitivity was 0.882, specificity was 0.768, F_1-score was 0.41, and MCC was 0.41. Calibration was adequate after isotonic recalibration (Brier score=0.055, calibration slope=0.826, and intercept=−0.295); a slope below 1.0 indicates mild overfitting, with predicted probabilities slightly more extreme than observed risks. The cross-validation-to-test AUC drop of 0.021 confirms reliable cross-validated estimates and minimal generalization error. The train-test AUC gap was 0.071, modestly larger than ideal but small enough to rule out severe overfitting given the consistent CV-test gap. Model A thus met the prespecified criterion of an AUC of 0.80 or more without ADL or IADL.

For comparison, model B achieved an AUC of 0.976 (95% CI 0.962 - 0.989) using GBDT on the held-out test set, with a sensitivity of 0.996 at the Youden threshold, a train-test AUC gap of 0.018, and a Brier score of 0.036. The 0.084 AUC gap between models B and A, and the near-perfect sensitivity of model B at the Youden threshold, quantitatively confirm the near-tautological relationship between IADL and the self-reported care-need outcome that motivated the prespecified decision to designate model A as the primary model.

Figure 2 compares the receiver operating characteristic curves of the 7 algorithms on the held-out test set. Boosting-based ensembles (GBDT, XGBoost, and LightGBM) and RF showed similar discrimination, while LR, SVM, and DT achieved slightly lower AUCs.

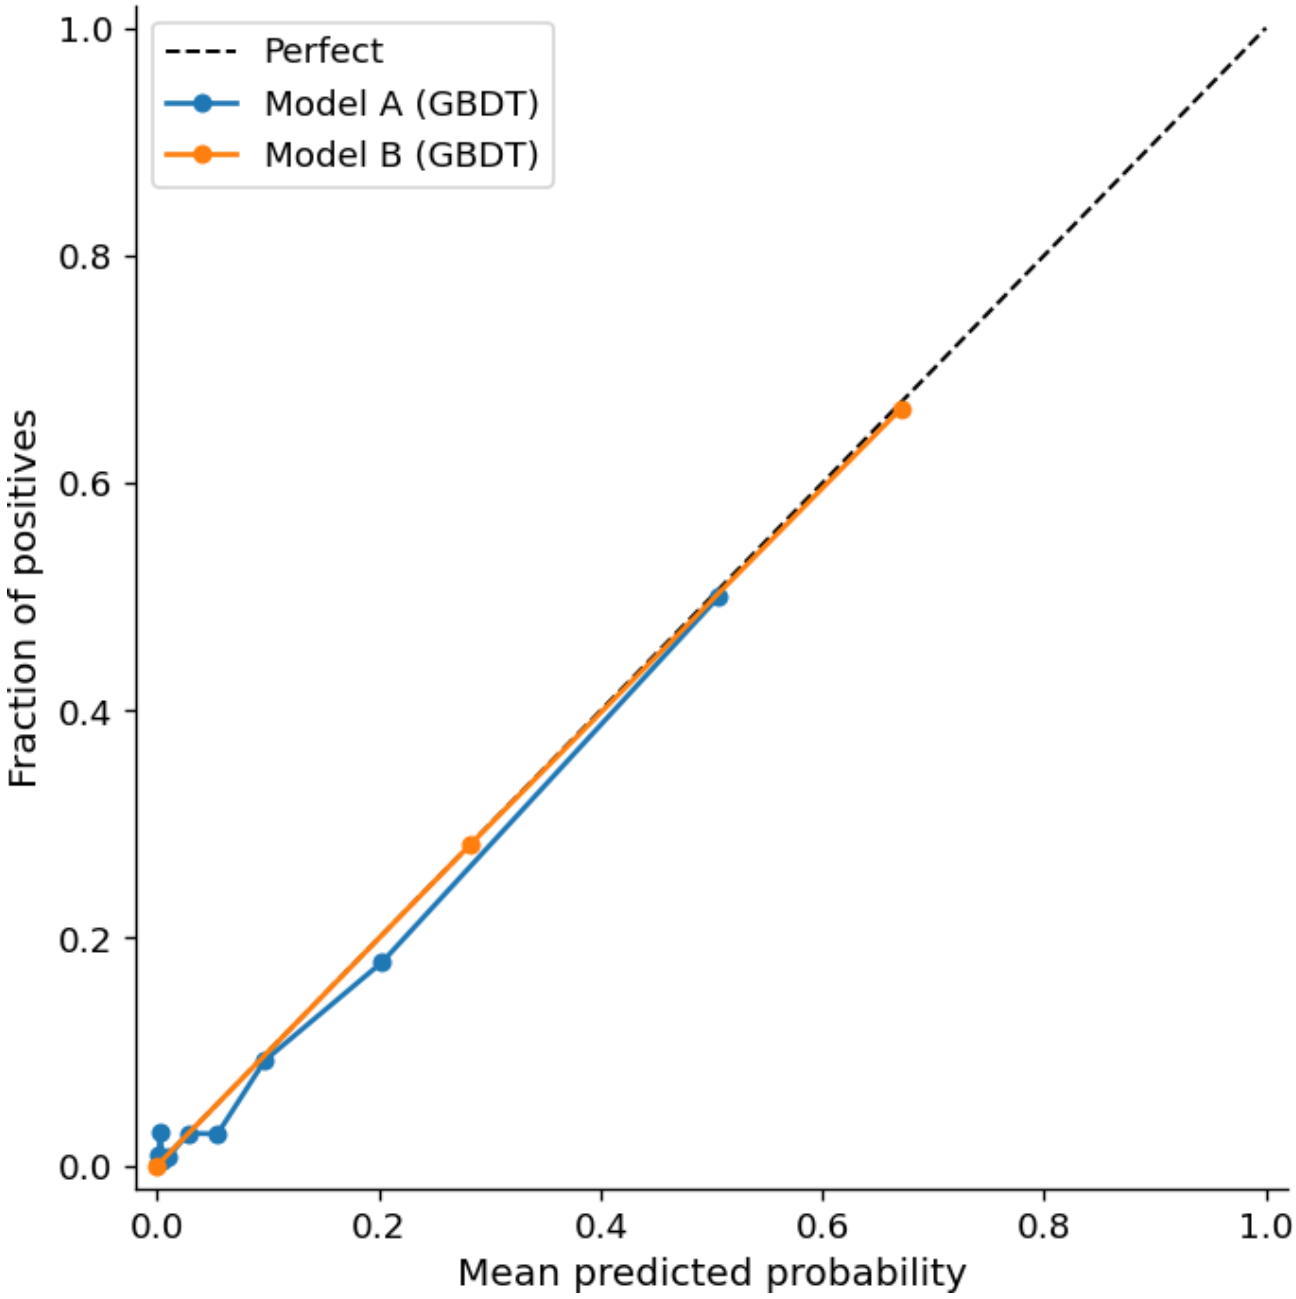
Figure 2. Receiver operating characteristic (ROC) curves for 7 ML models on the held-out test set using model A (primary, no activities of daily living [ADL] or instrumental activities of daily living [IADL]). AUC: area under the receiver operating characteristic curve; SVM: support vector machine; GBDT: gradient-boosted decision trees.



Calibration and Clinical Use

Calibration plots (Figure 3) show that both model A and model B track the perfect-calibration diagonal closely across the entire range of predicted probabilities observed in the held-out test set (0 - 0.7). Decision-curve analysis (Figure 4) demonstrates that model A provides positive net benefit relative to both "treat all" and "treat none" reference strategies across the full clinically plausible range (1% - 50%), suggesting potential use for upstream screening, pending external validation.

Model Interpretation

Figures 5 and 6 present the results of the SHAP analysis based on the best-performing model (GBDT, model A), with high rank stability across cross-validation folds (Jaccard=0.806 for the top 10), illustrating how individual predictors contribute to model predictions of care needs. Figure 5 shows the distribution of SHAP values for each predictor across individuals, indicating both the direction and magnitude of each variable's contribution to the predicted probability of care needs. Predictors are ordered according to their overall importance. Figure 6 summarizes the absolute SHAP values, providing a global ranking of feature importance.

XSL•FO

RenderX

XSL•FO
RenderX

SHAP analyses for model A identified age (mean |SHAP| 1.012, SD 0.073; range 0.910 - 1.093) as the most influential upstream predictor, followed by nutritional risk (NSI; mean 0.686, SD 0.103; range 0.552 - 0.809), employment status (mean 0.628, SD 0.116; range 0.484 - 0.769), depressive symptoms (mean 0.530, SD 0.093; range 0.420 - 0.606), self-rated health (mean 0.515, SD 0.068; range 0.443 - 0.587), cognitive function (mean 0.474, SD 0.069; range 0.398 - 0.567), household income (mean 0.432, SD 0.070; range 0.346 - 0.524), home modification level (mean 0.364, SD 0.061; range 0.270 - 0.407), BMI (mean 0.278, SD 0.032; range 0.244 - 0.316), and number of supporters when feeling depressed (mean 0.251, SD 0.056; range 0.176 - 0.308). All fold-level intervals excluded zero, supporting the stability of the rankings.

The leading predictors span demographic (age), nutritional (NSI), behavioral (employment), mental (depressive symptoms), subjective-health, cognitive, environmental (home modification), socioeconomic (income), and social-support domains, consistent with the study's second objective, indicating that care need behaves as a multidimensional construct. SHAP distributions were smoothly graded with no evident clustering, and all directional patterns were clinically interpretable: higher age, NSI, depressive symptoms, and home modification were associated with higher predicted risk; better self-rated health, higher cognitive function, and higher income were associated with lower predicted risk.

Sensitivity Analyses

For model A, the largest individual ΔAUC drops on removal and retraining were age (−0.005), self-rated health (−0.003), and employment (−0.001). All other top-10 predictors produced |ΔAUC| of 0.002 or less, with 4 (cognitive function, home modification, BMI, and depressive symptoms) showing trivial AUC increases when removed (ΔAUC=0.000 - 0.001), reflecting redundancy within the top-10 set rather than weakness of the included variables. No single nonfunctional variable produced a catastrophic drop, indicating a genuinely multidimensional signal (Multimedia Appendix 3).

When the outcome was redefined as 2 or more IADL limitations and/or 1 or more ADL limitations (1411/10,078, 14.0% prevalence, distinct from the primary self-report 875/10,078, 8.7% prevalence), model A achieved an AUC of 0.892 (95% CI 0.871 - 0.912), identical to its performance against the original self-reported outcome. This congruence between 2 substantively different outcome operationalizations suggests that model A's discrimination is not solely an artifact of self-report bias. However, because the composite outcome itself is based on functional impairment, this analysis primarily demonstrates that the upstream predictors are associated with functional limitation and cannot fully exclude measurement bias in the self-reported outcome.

Discussion

Principal Findings

This study aimed to identify determinants of care needs among community-dwelling older adults in Korea using a comprehensive set of multidimensional variables and explainable ML techniques. The principal finding is that care needs can be identified with good discrimination (AUC 0.892, 95% CI 0.866 - 0.918), adequate calibration (Brier=0.055 and calibration slope=0.826, indicating mild optimism in predicted probabilities), and positive clinical net benefit across the 1% to 50% threshold range using multidimensional nonfunctional features alone (model A). Model A met the prespecified discrimination criterion (AUC≥0.80) without ADL or IADL. Notably, when functional status variables were excluded to identify upstream risk factors, age, nutritional risk, depressive symptoms, self-rated health, employment status, cognitive function, home modifications, and household income emerged as the leading predictors, with high rank stability across folds (Jaccard=0.806). Discrimination is preserved when the outcome is redefined objectively (AUC=0.892), suggesting that the model captures a construct shared between subjective perception and objective functional impairment, though this does not by itself rule out self-report bias in the primary outcome.

The implications of this study are as follows. First, methodologically, the findings demonstrate the strong utility of explainable ML models in gerontological research. By comparing the predictive performance of 7 ML algorithms, the results suggest that ensemble learning methods are highly effective in capturing complex, nonlinear interactions among diverse risk factors inherent in gerontological data. Furthermore, the integration of SHAP values addresses the limitations of ML and provides transparent and interpretable evidence for prioritizing interventions. This study also replicates a recurring lesson in clinical-prediction ML: unusually high AUCs in survey-based studies often reflect outcome-predictor proximity rather than true upstream predictive value. The full-featured model B achieved an AUC of 0.976, but this reflects the near-tautological inclusion of IADL alongside a self-reported care-need outcome [17,18]; reporting model A as the primary result, alongside calibration, decision-curve analysis, and TRIPOD+AI–compliant documentation, provides a more honest characterization of model utility for screening.

Second, this study verified that care needs are multidimensional constructs shaped not only by physical function but also by upstream sociodemographic and environmental determinants across the following domains: demographics; health (eg, functional status, subjective health, nutritional health, mental health, and cognitive health); health behaviors (experience of falls and health-related behaviors); usage (medical use); social domains (participation, support); and the living environment. While previous studies have been limited to medical records or functional status, this study demonstrates that care needs are shaped by a complex interplay of sociodemographic and environmental factors alongside physical function.

Policy Implications

Based on the study's findings, several policy and practical implications can be proposed to support successful aging in place among older adults.

First, it is essential to prioritize functional status for immediate service allocation. Consistent with existing long-term care eligibility criteria, functional limitations (IADL and ADL) were identified as the strongest predictors of care needs in model B.

XSL•FO
RenderX

This finding validates the current assessment system, which prioritizes physical assistance for individuals with established functional dependence.

Second, targeting hidden-risk groups for preventive interventions is a critical secondary strategy. Model A highlighted the need for a preventive pathway. Even among older adults without severe functional impairments, specific multidimensional factors are associated with elevated care needs. The analysis identified advanced age, nutritional instability, depressive symptoms, cognitive decline, and poor housing conditions as key predictors. Therefore, a secondary pathway could be considered for older adults who are physically independent but exhibit these vulnerabilities. These cross-sectional associations are hypothesis-generating and require longitudinal confirmation before informing preventive deployment.

Third, care services must extend beyond physical support to include integrated lifestyle and environmental management. Specifically, services should encompass nutritional management, psychological counseling for depression, and cognitive training programs. Additionally, the strong predictive power of housing satisfaction and home modification levels underscores the importance of the living environment in aging. Housing interventions, such as barrier-free renovations and environmental adjustments, may be integrated into care strategies; whether such interventions delay the onset of physical dependency requires prospective evaluation [19].

Limitations

This study had several limitations. First, as a cross-sectional study, it identified associations but could not establish causal relationships between risk factors and the onset of care needs. Longitudinal studies are needed to track these trajectories over time. Specifically, the model identifies older adults whose contemporaneous profile is consistent with current care needs; it has not been validated as a forward-looking incidence-prediction tool. Longitudinal validation using the panel waves of the Korea Senior Survey is a planned next step.

Second, care need was self-reported and was therefore subject to the cultural, psychological, and gendered patterns of need-perception described in the gerontology literature [20]. This study mitigated this concern through (1) sensitivity analysis using an objective composite outcome (results were substantively unchanged: AUC=0.892), and (2) stratification by depressive symptoms (with discrimination preserved across quartiles). Future work should triangulate self-reported need with caregiver-reported and clinician-assessed need.

Third, the model underwent internal validation only (cross-validation and a held-out test split from the same survey); it has not been externally or temporally validated, and the calibration slope of 0.826 indicates that predicted probabilities would likely require recalibration in new settings. Geographic and cross-national validation in independent cohorts (eg, Japanese LTCI claims; the Survey of Health, Ageing and Retirement in Europe; and the China Health and Retirement Longitudinal Study or Chinese Longitudinal Healthy Longevity Survey) are required before clinical or policy deployment. The present model is framed as an evidence-based step toward, not a substitute for, such validation.

Also, the outcome variable, defined as binary care needs, should be expanded in the context of the LTCI system (eg, predicting grades 1 - 5 or preventive levels). Future research should apply multiclass classification models to predict specific levels of care needs, thereby enabling more granular and tailored resource allocation.

Finally, hyperparameters were prespecified rather than tuned. This avoids the optimistic bias from data-driven tuning, but the relative performance across algorithms should be interpreted as a comparison under common, nonoptimized settings, rather than as each algorithm's best achievable performance.

Conclusions

This study demonstrates that explainable ML models can accurately and transparently predict care needs among older adults using multidimensional survey data. While functional impairment plays a central role, care needs are also shaped by health-related, nutritional, social, and environmental factors. By highlighting the importance of nonfunctional indicators and emphasizing interpretability, this study offers a robust framework for the identification of care needs to inform proactive, community-based aging, and long-term care policies.

Abstract

Background: Technology can enhance the quality of life and social engagement for older adults; yet, many require assistance to use it effectively. In assisted living facilities, care workers play a crucial role in supporting residents' use of technology. However, little research has examined the experiences and challenges of care workers in this context.

Objective: In this study, we examine the perspectives and experiences of care workers in supporting older residents with technology.

Methods: We conducted semistructured interviews with 20 professional care workers in the United States, with an average of 4.9 years of experience working in assisted living facilities.

Results: The findings indicate that participants regularly provided technology support to their residents, while their perspectives on and acceptance of this technology support role varied. For many, this responsibility placed additional demands on their existing workload, requiring both explicit and nuanced physical and emotional labor input.

Conclusions: These findings underscore the need for greater recognition and systemic support for care workers as they increasingly take on the responsibility of facilitating technology use in residential care settings.

Introduction

Background

Assisted living facilities, a type of long-term care, serve older adults who can no longer live safely and independently at home. These residential communities provide housing and are staffed with care workers who support residents with a wide range of daily needs and activities [1]. Assisted living emphasizes person-centered care within a home-like environment, catering to a broader spectrum of care and social needs, including those of residents with complex medical conditions [2]. This sector represents a fast-growing segment of long-term care in the United States [3]. However, chronic staffing shortages pose ongoing challenges, which are exacerbated by the rapidly growing aging population [4]. In response, digital and emerging technologies have been explored as a promising means to help bridge this caregiving gap [5,6]. Examples include the use of information and communication technologies (ICTs) to facilitate proactive social engagement and health communication, as well as wearable devices for disease self-management [6-8]. These innovations have demonstrated significant potential to enhance the well-being of older adults, improve their quality of life, and reduce caregiver burden, both within long-term care settings and beyond [6,9].

Yet, the successful applications of technology depend on effective usage, and older adults often face barriers due to lower digital skills, physical and cognitive declines, and a lack of prior exposure to technology [10,11]. While the ownership of digital

XSL•FO
RenderX

technologies among older adults has grown [12], they continue to struggle with independent use, often experiencing anxiety, distrust, and avoidance of technology [13-15].

Consequently, studies consistently highlight that older adults' adoption and effective use of technology heavily depend on their immediate support networks, such as their children and community workers, for assistance with technology [16-18]. In assisted-living settings, care workers often serve as a critical source of technology support for older residents [19]. The term "care workers" refers to individuals who provide essential physical, emotional, and practical support to people requiring assistance with activities of daily living due to age, illness, disability, or other life circumstances [20]. This category encompasses a wide range of occupational roles, including nurses, nursing assistants, and care aides [4,20]. Despite variation in professional training and job titles, care workers share core responsibilities centered on facilitating mobility, administering medication, assisting with daily routines, and supporting the overall well-being of care recipients. Collectively, their labor constitutes a critical component of long-term care systems and plays a vital role in maintaining the quality of life of older adults [4,21].

Previous research on technology use in long-term care indicates that as more older residents adopt digital technologies, their reliance on care workers for technological support may also introduce additional work demand and challenges for care workers [21,22]. However, while emerging studies have begun to attend to those challenges [19,21], the literature has given little attention to care workers' perspectives on and experiences with providing such technology support to older residents. Consequently, there remain limited insights into how to best support care workers within increasingly digitalized caregiving environments.

Understanding the perspectives and experiences of care workers is particularly important given the vulnerabilities they face in the workplace. Caregiving often demands intensive physical and emotional labor, with care workers frequently expected to invest effort beyond their formal job requirements while receiving limited financial compensation and insufficient recognition from employers [21-24]. As the demand for assisted living continues to grow [25], providing better support for care workers is essential for enhancing staff retention and the quality of care.

To explore these issues, we conducted semistructured interviews with 20 care workers employed in assisted living facilities in the United States. Our study aimed to answer the following research questions:

1. How do care workers perceive their involvement in providing technology support?
2. What challenges do care workers face as they navigate the provision of technology support?

Our findings indicate that, although participants held varying views on their engagement in technology support, they consistently recognized it as an integral part of care workers' daily responsibilities. This role adds new dimensions of physical and emotional labor beyond their core job duties. Moreover, the heavy reliance of older residents on care workers for tech support highlights the need for greater recognition of this labor, as well as involving both care workers and older adults in the design of technology for older adults. Additionally, our findings highlight the importance of support programs that empower care workers, enabling them to establish clear work boundaries and navigate their roles more effectively in long-term care settings.

Literature Review

Care Workers' Roles and Workload

Care workers in long-term care broadly refer to individuals who deliver direct care services to people needing daily assistance, typically older adults, in home or residential settings [26]. In residential long-term care facilities, such as assisted living, these professionals are commonly referred to as care assistants, social workers, nursing assistants, and other health care professionals [20,27]. Prior studies indicate that care workers' roles and job responsibilities are often loosely defined, primarily determined by the individualized needs of their residents [28]. This role ambiguity is particularly pronounced in residential care settings, where person-centered care is a key emphasis [29,30]. While fostering meaningful relationships with residents is central to care work, this closeness can blur professional boundaries, making it difficult to delineate responsibilities [29,30]. As a result, care workers frequently feel an overarching sense of duty for residents' well-being, taking on multiple roles beyond their formal job descriptions [28,30]. Qualitative studies on care workers' attitudes toward their responsibility further highlight a persistent tension between care workers' commitment to holistic resident care and the emotional strain of multitasking, burnout, and heavy workloads [23,31].

Commonly recognized care workers' routine responsibilities include, but are not limited to, hygiene assistance, medication management, mobility support, case management, and administrative tasks [32]. While these duties already demonstrate the labor-intensive nature of caregiving, research further reveals that many essential caretaking roles and tasks remain unseen and unpaid [23,28]. These include the emotional investment involved in building trust relationships with clients, managing their clients' emotional responses, and regulating one's own emotions in high-stress environments [33,34]. Additionally, care workers often coordinate to facilitate communication between their clients, health care providers, and other third parties [19,28]. Ongoing studies have continuously advocated for greater recognition of care workers' contribution, particularly the less recognized aspects of their labor, to improve their overall financial and social well-being [23,29].

Technology Use Among Older Adults in Long-Term Care

A growing body of literature has explored the role of technology in enhancing the quality of life and supporting independent engagement in social and health management activities among older adults in long-term care settings [7,9,35]. ICTs, such as computers, laptops, smartphones, and mobile apps, play a crucial role in enabling older residents to maintain connections with family and friends outside of facilities and engage in various

XSL•FO
RenderX

leisure activities [7,36,37]. The use of social media and videoconferencing platforms has been shown to effectively reduce social isolation and feelings of loneliness [37-39]. Beyond social engagement, ICTs are also widely used to deliver essential care services, such as telemedicine and mobile health (mHealth) applications, which facilitate the remote provision of routine care and health information [40,41]. These applications help deliver effective personalized care [40]. Moreover, technologies gaining popularity in long-term care facilities also include wearable devices, such as smartwatches and fitness trackers [6,42], as well as assistive technologies, such as autonomous wheelchairs, designed to enhance functional capacities [43]. These tools support mobility, help monitor health indicators, promote physical activity, and support self-management of chronic diseases [40-43].

The growing use of technologies within long-term care facilities is partly driven by older adults' voluntary adoption, as evidenced by the steady increase in personal device ownership within this demographic [12]. Additionally, as the long-term care sector continues to experience staffing shortages, these technologies are increasingly recognized for their potential to bridge workforce gaps [44]. Consequently, many facilities have expanded their technological resources by providing residents with access to ICT, assistive, and wearable devices, while actively promoting their use [9,17,37,45]. In some cases, technologies have become so embedded in facility operations that residents must engage with them to carry out routine activities and access services and information within the facility [45]. This trend underscores the increasing significance of technology in the daily lives of older residents in long-term care.

Dependency, Technology Support, and Potential Challenges

While most technologies require the direct involvement of older adults, studies have highlighted the heightened challenges that older users face in realizing the intended benefits of these tools [18,46]. Older adults exhibit wide variation in digital literacy, prior experience with technology, and physical or cognitive abilities, all of which affect their capacity to use digital tools independently [13,14,46]. Despite the growing availability of technological resources in long-term care facilities, individuals with higher levels of technological proficiency or prior experience are more likely to engage with these tools [17]. In contrast, those with limited experience or skills often remain disengaged, even when they recognize the potential benefits of technology use [16,17]. Moreover, regardless of their skill levels and motivation, many older adults still struggle with basic interactions due to age-related declines in vision, hearing, fine motor skills, or cognitive processing [21,36]. The continuous diversification of devices and interfaces, each requiring different levels of engagement, from basic device operation to security credential management, can further exacerbate the distrust and anxiety associated with technology use for older adults with cognitive and functional impairments [14,15,46].

Consequently, older adults often rely on close social networks for assistance in using technology effectively [16,18]. These networks typically include family caregivers or other younger family and community members who live in close proximity to older adults [16-18]. In long-term care facilities, several studies have shown that professional care workers often become the primary source of technology support for older residents [19,21]. Nevertheless, providing technology support can be challenging [21,22]. For instance, Hardy et al [22] found that facilitating videoconferencing for cognitively impaired older residents was physically demanding, requiring multiple steps to connect them to virtual platforms. Similarly, Chew et al [21] reported dissatisfaction was found among care workers tasked with setting up and managing virtual visits during the COVID-19 pandemic, a responsibility they found burdensome due to visitor restrictions that placed greater reliance on digital communication.

Despite increasing integration of technology in long-term care facilities, limited research has specifically examined care workers' experiences with providing technology support to their older residents. While prior research emphasizes the importance of care workers in daily resident support, little is known about how technology-related responsibilities intersect with their existing workloads. This gap in the literature risks rendering this emerging aspect of care work unrecognized, thereby negatively affecting their financial and social well-being [22,23]. By examining the direct experiences and perspectives of care workers, this study aims to inform strategies that better support them in long-term care settings.

Methods

Participants

We conducted semistructured interviews with 20 individuals working in assisted living facilities in the Greater New York area. Participants were eligible if they had worked in any care worker role at an assisted living facility for more than 1 year and were at least 18 years old. To recruit participants, we contacted assisted living facilities in the region and provided managers with a detailed explanation of the study's objectives. Upon their approval, recruitment flyers were distributed via email, and managers and supervisors referred potential participants to the research team.

The final sample included 20 participants (9 male and 11 female), with an average of 4.9 (SD 3.08) years of work experience and an age range of 23 to 56 (mean 38.15, SD 8.23) years. All participants were paid professional care workers employed by an assisted-living facility at the time of the interviews. While the resident base in these facilities exhibits varying levels of independence and diverse health needs, many live with chronic conditions, including diabetes, hypertension, or heart disease, and require mobility support, including assistance with walking and using mobility aids. Some also require monitoring for safety or adherence to care routines.

All participants' job titles were self-reported. Nine participants identified as caregivers or care assistants; 6 held medical-care-oriented roles, such as nurse or medication assistant, and 4 worked in social-care-oriented roles, such as case managers and activity assistants. One participant held an administrative role but still reported frequent direct interactions

XSL•FO
RenderX

and support for residents. A detailed breakdown of participant demographics is provided in Table 1. Job descriptions are synthesized from participants' accounts and sources, including professional associations such as the American Nurses Association, government websites like the U.S. Department of Health and Human Services, and career websites like Glassdoor. While they offer a general understanding of each role, they may not fully capture the daily experiences of care workers, a discrepancy explored in the Results section.

Table 1. Participant demographics.

ID	Gender	Age (years)	Work experience (years)	Job title
P1	Female	48	5	Case Manager[a]
P2	Female	40	8	Case Manager
P3	Female	56	10.5	Case Manager
P4	Male	39	3	Caregiver[b]
P5	Male	33	6	Caregiver
P6	Female	39	10	Caregiver
P7	Female	32	3	Care Assistant[b]
P8	Female	35	2	Care Assistant
P9	Female	32	4	Care Assistant
P10	Female	30	3	Care Assistant
P11	Male	23	3	Care Assistant
P12	Female	29	2	Care Assistant
P13	Male	38	7	Nurse[c]
P14	Female	47	1.5	Nurse
P15	Female	51	1	Nurse
P16	Male	40	8	Nurse
P17	Female	30	1	Nursing Assistant[d]
P18	Male	37	5	Medication Assistant[e]
P19	Male	35	7	Activity Assistant[f]
P20	Female	49	8	Administrator[g]

[a]Case managers are health care professionals who help clients with health management, service coordination, and patient advocacy.

[b]Care assistants, caregivers, or personal care aides are care professionals who provide a broad spectrum of services to those who need assistance with daily activities. Their duties include personal care, domestic care, and companionship.

[c]Nurse is a health care professional who attends to patients' biological, physical, and behavioral needs. In the United States, all nurses are required to complete formal training to obtain licenses and certifications.

[d]Nurse assistants provide support in daily activities, health monitoring, and hygiene for clients. Different from nurses, nursing assistants are not always certified.

[e]Medication assistant helps administer medications in a hospital or other care facility.

[f]An activities assistant helps to plan events for socialization and enjoyment in a variety of settings.

[g]Long-term care administrator plans, organizes, directs, and manages the operation and implements policies.

Data Collection

An interview guide was developed to facilitate open-ended, semistructured interviews (Multimedia Appendix 1). The guide consisted of several key topics, with the first few questions concerning participants' job titles and responsibilities, as well as their day-to-day work life. The latter part of the questions focused on participants' perceptions of their residents' technology use and experiences helping their residents with technology-related inquiries. This set of questions is followed by those concerning their use of technology. All interviews were conducted virtually using the videoconferencing software of the participants' choice (eg, Zoom). Each session lasted up to 60 minutes, allowing for an in-depth discussion of their experiences. With participants' consent, all interviews were audio-recorded and transcribed using transcription software. Each transcript was then carefully reviewed and manually corrected to ensure accuracy.

Data Analysis

We used a grounded theory approach to identify recurring patterns within our interview data [47]. The process began with

XSL•FO
RenderX

open coding, where transcripts were systematically examined to label key concepts related to care workers' perspectives and experiences with tech support [48]. We then conducted axial coding, organizing related concepts into broader categories, referred to as phenomena, such as recurring events, actions, or interactions that illustrate how care workers navigate their tech support roles. Lastly, we engaged in selective coding to synthesize the phenomena into a cohesive framework, capturing overarching themes and relationships within the data. This iterative approach continued until data saturation was achieved, ensuring a comprehensive understanding of participants' experiences.

Ethical Considerations

The study received approval from the institutional review board (IRB) at Rutgers, The State University of New Jersey (IRB# Pro2021001731). At the beginning of each interview, participants were informed about the research procedure and their rights as participants, including the voluntary nature of participation and the right to withdraw at any time. All participants provided voluntary, informed, and written consent to participate in the study and had the interview audio recorded. All recordings were deleted upon transcription. The research team ensured that the transcripts contained no identifying information about the participants and that all data was stored on a passcode-protected drive accessible only to the research team. As a token of appreciation, participants received a US $20 e-gift card upon completing the interview.

Results

Overview

Through an analysis of participants' experiences in providing care services to residents, three key themes emerged: (1) the current state of care workers' daily responsibilities, (2) care workers' perspectives on their engagement in technology support, and (3) challenges and labor demands associated with providing technology support. Since this study was conducted in an assisted living setting, we use the term "resident" to refer to the older adults served by the participants. This terminology also aligns with how participants commonly referred to those in their care.

The Current State of Care Workers' Daily Responsibilities

Multifaceted Job Responsibilities

At the beginning of each interview, participants were asked to describe their job titles, primary responsibilities, and a typical day at work. Despite variations in job titles, all participants reported being actively involved in providing a range of direct care services to residents, extending beyond the generally defined duties associated with each job title. Caregivers, for instance, described a wide array of duties addressing residents' individual needs holistically, including assistance with meals, hygiene, medication, mobility, and companionship. Participants in medical-care-oriented positions, such as nurses and medication assistants, whose primary responsibilities involved medication administration, condition monitoring, and care plan development, also frequently assisted with personal care tasks, including hygiene and mobility support. Similarly, the administrator, despite primarily handling administrative duties, also engaged directly with residents and their families to ensure their needs were met. Across participants' narratives, the extensive list of daily tasks highlighted the labor-intensive and multifaceted nature of their work.

> *I help in assisting condition management...administering medications...monitoring them, and ensuring that they carry out the proper exercises...I also help them with grooming and hygiene needs...household tasks like washing the dishes and cleaning up pots.* [Participant 6, caregiver]

> *Medication administration, insulin administration, doctor's visits...Assistance with transfers, ambulation, personal hygiene...On some occasions, nurses would help with showers if we had a shortage of nurses. I am in charge of a lot of responsibilities that change on a daily basis.* [Participant 14, nurse]

There was a strong consensus among the participants that their primary goal was to provide responsive, individualized care tailored to residents' needs. Consequently, their daily tasks were not rigidly defined but instead heavily shaped by evolving demands of those they cared for. The fluid nature of their work demanded flexibility and adaptability to provide timely and effective support, requiring them to juggle multiple responsibilities and roles. However, the continuous demands of addressing age-related frailty and the complexities of care sometimes led to experiences of burnout.

> *In the mornings, people usually call on the system for assistance if they need to. And then they start looking for things to do. We also accompany them if they want us to or if they need supervision. So, it's not like I have a specific role that you carry out every day. I have to switch and perform different roles.* [Participant 19, activities assistant]

> *My typical day at our facility was kind of hectic because I had a lot of roles to take on in the facility. That is the administration of medicine, and also daily monitoring and reporting of vital signs. These residents, most of them are old, so they get sick quite often. On a busy day, on average, my day was kind of tiresome because I had to do this work...it was always tough for me.* [Participant 13, nurse]

Among all these responsibilities, technology support consistently emerged as a significant and recurring task, which we explore in detail in the next section.

Tech Support as a Frequent Need of Residents

When initially outlining their responsibilities, participants rarely mentioned providing technology support. However, upon deeper reflection on their daily interactions with residents, in the context of technology use, it became clear that technology is well-integrated into residents' lives, but often at the condition of their ongoing assistance. Across the board, participants reported varying levels of digital technology use among residents in their facilities, and that many residents frequently

XSL•FO
RenderX

relied on their assistance to use these technologies. The most used devices were residents' personal smartphones and tablets, which they primarily used to access a range of mobile apps. Communication apps, such as WhatsApp, Facebook, and Skype, were frequently used to stay connected with family members and access social networks outside the facilities, as well as to stay informed about news. Additionally, some residents were observed using health and wellness applications, including those for fitness tracking and medication management. A smaller number of participants noted residents using gaming apps and streaming services, such as YouTube. Beyond personal devices, some facilities provided residents with access to shared technological resources, actively encouraging their use. For instance, one facility offered virtual reality equipment to enhance exercise routines, while another maintained a computer lab for residents' personal use. In many cases, participants noted that residents, whether using personal or facility-provided technology, frequently sought their assistance when encountering difficulties or needing additional guidance.

> *They mostly use the apps and platforms I mentioned to reconnect with their family members back home. So, these are the most commonly used in the facility...Some use it on their own, while others seek assistance from me and other staff working in the facility.* [Participant 5, caregiver]
>
> *They like to make video calls with their family, like Skype, and use the laptop. Sometimes, we help them out with that. And there are VR fitness oculars that we sometimes use to engage them in physical activities. And they actually also require assistance with using them.* [Participant 12, primary caregiver]

When explicitly prompted to reflect on the frequency of technology support, participants not only revealed the high occurrence of such tasks but also the high percentage of residents performing them. This suggests that providing technology support becomes an essential part of their daily duties, alongside their other caregiving responsibilities.

> *(Q: Do residents often ask for instructions on using these technologies? [referring to residents' phones]) Yeah, most of the time, 80% of time I would say.* [Participant 18, medication assistant]
>
> *(Q: Do residents often ask for instructions [referring to the in-facility computer lab]?) Yeah, I'd say a big percentage of them. They ask for help whenever they need help and instructions.* [Participant 13, nurse]

Care Workers' Perspectives on Their Engagement in Technology Support

Care Workers' Degrees to Accepting a Technology Support Role

As participants reflected more deeply on residents' technology use and support needs, their narratives revealed varying attitudes toward the boundaries between providing tech support and their assigned job responsibilities. On the one hand, some participants viewed tech support work positively, embracing it as a natural extension of their duties. This perspective was often rooted in the belief that technology assistance represents an emerging and essential need among residents. Given that their responsibilities were already seen as multifaceted, they felt that addressing these needs naturally aligned with their role in providing comprehensive care.

> *(Q: Do residents help each other with technology?) No, they don't. Because it's the staff's job to help them.* [Participant 8, care assistant]
>
> *When residents have difficulties with technology or ask for help, we were all more than happy to help with computers or cell phones...because it was something for them.* [Participant 14, nurse]

In contrast, other participants perceived technology support as outside the scope of their assigned responsibilities. While not entirely opposed to assisting residents, they emphasized the challenges associated with incorporating an additional tech support role into their already multifaceted duties and demanding schedules. This burden was further exacerbated by staffing shortages in long-term care facilities. In response, some participants advocated for alternative solutions, such as hiring dedicated technology support professionals, assigning specific staff for tech-related tasks, or implementing resident training programs to promote digital independence and reduce reliance on care workers for technical assistance. These varying perspectives demonstrated the tensions between evolving care demands in the digital age and traditional understandings of caregiving.

> *Staff is busy. It's not always feasible to help somebody. They have their own work to do.* [Participant 15, nurse]
>
> *Problems arise due to not having enough staff to show residents how to use it...I know a lot of facilities right now experience a lack of staff. Especially with using technology, I believe it needs to be professional, in some way.* [Participant 3, case manager]
>
> *It would be a nice development if all the facilities can give some kind of sensitization or training to residents on how to operate basic technologies themselves, other than leave the tasks solely to staff.* [Participant 4, caregiver]

Dual Recognition of Technology as Essential and Independent Use as Unachievable

Despite different opinions on whether technology support was a part of their core duties or not, all participants continued to assist residents with technology. This was driven, in part, by a shared acknowledgment that technology use is important to their residents and particularly beneficial in providing the familiar emotional support that participants were unable to offer. As identified by existing studies, one of the major challenges older adults residing in long-term care facilities face is experiences of loneliness and isolation due to reduced opportunities to interact with their families and neighbors [49]. Participants' narratives also echoed these findings, underlying the prevalence of this issue, particularly among those whose families did not visit regularly. In this case, ICTs served as the primary tool for maintaining residents' communication with their social networks outside the facilities.

XSL•FO
RenderX

> *They seek out help regularly, because it's not something they can do without. They have to stay in touch with their loved ones, and they rely on technology to receive daily reminders about their medications.* [Participant 16, nurse]

> *A lot of families come in to visit, but some of them don't...Nowadays, Facebook and Skype is probably the best way since technology makes it much easier.* [Participant 15, nurse]

> *They would have a better quality of life if they can actively participate using technology to improve their memory and well-being, because technology has its minuses and pluses. But overall, it keeps people connected in such a disconnected world.* [Participant 2, case manager]

Moreover, there was a collective acknowledgment among participants that the issue related to residents' heavy reliance on care workers for tech support is inevitable. As revealed by participants, it is simply not possible for residents with heightened age-related physical and cognitive disabilities to use technologies independently. While their deep understanding and empathy for their residents are admirable, it is also crucial to attribute the root cause of this issue not to the inevitable age-related constraints, but to the flawed, existing technology systems that consistently overlook the accessibility needs of older adults [50]. In one facility where a voice assistant was used, the participant demonstrated ongoing difficulties; as such, the device consistently failed to recognize and execute the commands of Spanish-speaking residents. She explicitly attributed her residents' reliance on staff for tech support to the lack of inclusive technology design, highlighting how language barriers further complicated their ability to navigate digital tools independently.

> *I think it's normal for someone of their age or physical situation to sometimes require some assistance with the use of technology.* [Participant 12, caregiver]

> *Not everybody's able to do it due to memory issues...so we're always there to assist them.* [Participant 15, nurse]

> *It's very difficult for bilingual residents to use, because in our facility we have Spanish-speaking residents. They have accents and intonation when speaking English. It's very hard for voice assistants to pick up those particular commands from them. So, there are a lot of errors...Those are the reasons related to the interface of those particular technologies that pose difficulties for them...they seek out help regularly.* [Participant 16, nurse]

Technology Support as a Rewarding Experience

While perceptions toward the role boundaries between caregiving and technology support varied, there is a general acknowledgment that the experience of tech support could be rewarding. For instance, participants shared sentimental stories of helping residents reconnect with a long-lost family member through videoconference or experience the outside world through virtual reality devices. Furthermore, participants' kindness and efforts in providing technology support were reciprocated by residents' gratitude and positive emotional feedback, allowing participants to have a sense of meaning and fulfillment in their work. By supporting residents with technology-related issues, participants also strengthened trust and fostered positive relationships, creating a more positive work environment.

> *They do appreciate my assistance with assisting them with their technology.* [Participant 4, caregiver]

> *By integrating them with necessary VR applications, we are able to take them back to their favorite places, like going on tours or climbing mountains...While such interventions can take hours...they responded positively. So it wasn't that stressful.* [Participant 16, nurse]

> *I was helping a resident establish a full connection to a podcast they were listening to. They needed assistance to get the full connection, and they were very happy...We are there to help all of them, so I am always available to help any resident who needs assistance.* [Participant 13, nurse]

Challenges and Labor Demands Associated With Providing Technology Support

The Repetitive Burden of Tech Support

Although not all participants explicitly voiced complaints and concerns about the workload associated with providing tech support, a closer examination of their detailed experiences revealed that this role was both physically and emotionally demanding. When prompted to share their observations on the coping strategies residents used to deal with technology-related difficulties, only a few participants mentioned occasional instances of mutual support among residents. In most cases, participants identified that residents relied primarily on staff for assistance, positioning care workers as the first responders to residents' tech-related requests with the expectation that they would be readily available whenever needed. The high volume and frequency of these demands further exacerbated their already labor-intensive primary responsibilities, contributing to burnout, as outlined in the first section.

> *I feel like their greatest strategy is the fact that they actually have the staff to rely on. So, whenever they have difficulties and all of that, they have the staff at their disposal to help them out.* [Participant 7, care assistant]

> *The only strategy they have is calling for help. So, when they aren't understanding, you have them yelling your name, trying to call you. So sometimes you can have like five people calling you at the same time. It can be really draining and challenging.* [Participant 18, medication assistant]

Moreover, the workload was further complicated by the repetitive nature of technology-related requests, which often involved recurring issues. As previously mentioned, residents required the most support with emerging digital technologies, particularly mobile apps on their phones and tablets. Modern

XSL•FO
RenderX

apps often require users to navigate multistep interactions, manage various settings, and adapt to frequent updates to fully utilize their features. Consequently, assisting residents often involves step-by-step navigation and detailed instructions. However, the initial guidance efforts seldom led to meaningful learning or skill acquisition among residents, leading to repeated interventions for the same issues. As a result, tech support work often became a repetitive task, requiring significant patience, time, and emotional energy, which further strains participants' already demanding roles.

> *You just try to open the apps, see the updates, and then just explain to them what the problem is and show them how they'll go about it. Then the next time they are in the same situation.* [Participant 19, care assistant]

> *Initially, he was unsure of how to use it (an app that tracks residents' movement). I explained that when he wakes up, he needs to open the app, place the phone either on his body or hold it in his hand...He didn't fully understand on the first day, so I had to repeat the instructions multiple times.* [Participant 9, care assistant]

Additional Responsibilities Associated With a Tech Support Role

In addition to the taxing and multifaceted nature of juggling multiple roles and responsibilities, their experiences also revealed that "tech support" encompasses far more than simply addressing technical difficulties. Instead, it often required participants to take on multiple responsibilities, often involving complex coordination tasks. Many participants found themselves acting as coordinators, facilitating communications between residents and third parties, such as families and medical providers. These coordinating tasks included setting up the devices, coordinating schedules with various external parties, and even securing permissions for communication when needed. These responsibilities were particularly pronounced for participants assisting residents experiencing cognitive impairments.

> *I always double-check with the family if it's okay to [call] or no, because you don't know what they're gonna open up and you know viruses and everything else on the internet.* [Participant 15, nurse]

> *We tend to help them do that because some of them don't get to have their telephones with them. So, we tend to call their families for them on a weekly basis or, in special cases, like the woman (with dementia and only remember her child at times) that wanted to see her child at the time. So, we tend to communicate to the families for them.* [Participant 10, care assistant]

Several facilities that offered communal technology resources and devices for residents actively promoted their use to enhance residents' health and social engagement. However, these technologies were rarely used by residents without assistance from participants. In facilities where these technology resources were more established, there were formal guidelines regulating residents' use of technology. Participants' narratives suggest that such regulation stems from the facility's concern about potential damage to the high-cost devices. As a result, participants were directly assigned supervisory responsibilities by their employers to ensure the proper functioning, maintenance, and safe use of these devices. Additionally, while the purpose of technologies such as medicine dispensaries is to facilitate residents' disease self-management, their lack of technology proficiency also led to heightened concerns among participants about the potential health hazards resulting from technology misuse. Consequently, participants voluntarily took on supervisory roles to monitor residents' technology use.

> *In our facility, we have rules because if residents are allowed to use this technology on their own, they may mess things up. So, we guide them to ensure maximum utilization of the technology.* [Participant 13, nurse]

> *This digital medication dispenser, there was a day a resident who is on medication forgot to take her medication. So, she was having doubts since she had missed a dose...I just had to monitor her to ensure that she made use of the dispenser in my presence.* [Participant 20, administrator]

Moreover, intertwined with their coordination role, participants often had to advocate for technology use among residents who avoided it for various reasons, particularly in facilities with communal technology resources. Aligning with prior research on older adults' reduced interest in technology adoption [11], participants observed varying degrees of technology hesitation, especially among the oldest residents. Despite well-intentioned efforts to introduce mobile apps and other emerging technologies to enhance residents' health and social well-being, these efforts were sometimes met with dismissiveness or resistance. Encouraging reluctant residents to engage with technology required patience, empathy, and careful navigation of their moods to foster a supportive and encouraging environment.

> *Most of them are a bit older than I think, and for them to embrace the technology, they need so much convincing.* [Participant 19, activity assistant]

> *I had an encounter with one of the residents who was basically not in the mood because...she didn't want to actually use the app...I tried to convince her that it would be beneficial for her to try it.* [Participant 7, care assistant]

Emotional Dimension of Tech Support

Navigating technology later in life without prior exposure to digital learning experience can be emotionally challenging [51,52], particularly for older adults who wish to use technology but struggle to do so. Participants found these difficulties often triggered a range of negative emotions among residents, including frustrations, confusion, and mood swings, which created challenges in their daily work. As a result, participants were responsible not only for addressing technical problems but also for managing residents' emotional responses while using technologies. To de-escalate these situations, participants used various strategies, such as providing encouragement,

XSL•FO
RenderX

offering empathetic guidance, and maintaining patient and supportive communication.

> *What I've observed is that it's become difficult for some of them; they get depressed, or they feel less motivated because they are trying to access these technological platforms, but it's hard for them. Whenever I find them in these kinds of situations where they feel down or their mood is low, I initiate interactive conversations and some fun activities.* [Participant 5, caregiver]

> *They start with panic because something they really need is not working...So the interaction usually begins in a panic mode. After interacting with them, I assured them that we will take care of it and fix the issue as soon as possible. Then they calm down.* [Participant 6, caregiver]

Defensiveness was a particularly common emotional response among residents who highly valued their independence and believed they possessed sufficient knowledge. This often manifested as stubbornness or a reluctance to seek help. While frequent tech support requests could overwhelm participants' already strained schedules, residents' intentional avoidance of seeking help posed a different challenge. This was especially true for those managing communal technological devices, as they often had to resolve issues caused by residents' mishandling. To manage these situations, participants adopted proactive and sensitive approaches when offering assistance, ensuring that residents felt their independence was respected while still receiving the support they needed.

> *Some of these residents are stubborn...because they think they know, but they don't know. That's why it's important for them to seek help. Some of them are actually stubborn because they always assume they know things, but whenever they're trying to apply, they always mess up.* [Participant 13, nurse]

> *Most of the time when they come around..."I need assistance with this. I need to check this, I need to check that, and can you please help?"...If it's someone who couldn't act fast or you know that this person needs assistance, you just ask the person, Can I help you? Can I help you to do this?* [Participant 11, care assistant]

In turn, managing residents' emotions negatively impacted participants' own emotional well-being and can be mentally draining [53]. Yet, their emotional labor often goes unrecognized by their employers and even by the participants themselves, overshadowed by the deep emotional bonds they share with residents [54]. Correspondingly, in this study, while participants did not explicitly describe technology support work as emotionally burdensome, the constant need to navigate residents' frustrations with patience and sensitivity, alongside physical tasks, suggested that such work takes an emotional toll. Participants' narratives made it clear that to provide effective and satisfying technology support, they frequently needed to regulate their own emotions, even in the face of challenging behaviors.

> *One of the most important things in working in assisted living is that you have to always be calm, even when you are not pleased with some behaviors of the residents; you have to be the one who has to be calm.* [Participant 7, care assistant]

Discussion

Overview

Recent studies on technology use in long-term care facilities revealed the frequent need for care workers to provide technology assistance [21,22]. Nevertheless, research examining care workers' experiences with tech support remains limited. This underscores the need for a deeper understanding of their evolving role in the digital age. This study specifically focuses on the perspectives and experiences of care workers in assisting residents with technology in assisted living settings. In what follows, we discuss implications for better recognizing, supporting, and including care workers in the integration of technology in long-term care.

Increase Recognition of Labor Associated With a Tech Support Role

Our findings highlight that caregivers' technology support extends beyond assisting with devices, encompassing various roles and tasks generated by one seemingly singular tech support role. Echoing existing studies [21], tech support often leads to various coordination activities involving external parties, such as residents' families and health providers. Additionally, our studies uniquely highlight the supervisory responsibilities associated with maintaining and ensuring the safe use of technology devices in care facilities. This burden is particularly pronounced among participants in facilities that implement on-site technological solutions, contributing to workplace stress. As participants indicated, the potential damage to high-cost in-facility devices or residents' misuse of technology can be perceived as a failure in their professional practice. Such pressure, in turn, can compel them to take on even more supervisory and support tasks to mitigate risks, ultimately creating a relentless cycle of labor. As vulnerable workers, even minor perceived failures can overshadow their significant daily contributions, highlighting the urgent need for greater recognition of their labor input.

This study also highlights the emotionally challenging nature of tech support in caregiving. Research increasingly acknowledges the emotional labor inherent in caregiving, defined as the regulation of one's emotions to align with expected professional expressions, even when they conflict with personal feelings [33,53]. Consistent with prior studies [13,51], our participants described how older adults' struggles with technology often trigger frustration, confusion, and emotional outbursts. Consequently, caregivers frequently become the direct target of these frustrations, absorbing residents' emotional distress while striving to offer patient and compassionate support.

Despite being an integral part of resident care, these additional layers of labor associated with a tech support role remain largely unrecognized. Job descriptions and verbal accounts of caregiving

XSL•FO
RenderX

roles often fail to acknowledge the full extent of tech support responsibilities. As previous research noted, care workers' dedication to their professional identity should not justify the normalization of excessive labor [23,28,29]. The continued lack of recognition perpetuates the devaluation of caregiving work [28]. Therefore, given the rapid digitalization of the care sector, this study emphasizes the need for ongoing research and policy interventions to recognize the physical and emotional investments made by care workers in providing tech support and how these responsibilities contribute to their already demanding workloads. Additionally, employers must implement stronger support systems, such as on-site mental health services and training, and recognize this labor through improved compensation and workplace policies.

Technology Use, Design, and Implementation in Long-Term Care Needs Ongoing Careful Evaluation

We found a wide range of technologies are used in assisted living, including residents' personal devices and assistive technologies provided by the facilities. Participants also expressed an overall positive attitude toward residents' use of technology and their willingness to offer support. This willingness stemmed not only from residents' requests but also from participants' genuine belief that technology enhances the quality of life for residents. These findings align with the broader discourse and research on technology in long-term care, where its potential to improve the social and physical well-being of older adults has been widely acknowledged [6,7].

By highlighting how technological innovations introduce new responsibilities for care workers, this study calls for a more nuanced perspective in the ongoing discourse and research on the use of technology and caregiving in long-term care. While technologies can enhance service delivery, support aging independence, and assist care workers, their successful implementation should not be discussed in isolation from the labor of care workers. Too often, the discussions around technology in long-term care focus on the potential for automation to replace routine aspects of caregiving, which risks further devaluing care work [55]. Yet, as this study and others have shown [21], the success of residents' technology use and the implementation of new devices in facilities remain heavily dependent on the support of care workers. Future studies should evaluate the effectiveness of technology use in long-term care by centering care workers' perspectives on both the benefits and shortcomings these innovations introduce.

Moreover, the significant challenges older residents experienced when using these devices and their reliance on others for support, as identified by participants, highlight the persistent digital divide and the lack of age-inclusive design thinking in current technology systems [50,56]. While some may argue that such challenges are unique to the current cohort of older adults, who may have had limited opportunities to engage with technology earlier in life, other challenges, particularly those associated with age-related health conditions such as cognitive impairment, will remain relevant going forward. These findings further demonstrate the lack of inclusivity in existing technology design and the urgent need for improvement.

Existing studies on the technology use of older adults have advocated for a user-centered approach, emphasizing the importance of involving older adults in the design process [57-59]. Building on this, our study recommends the inclusion of care workers in technology design to integrate their expertise and acknowledge their central role in supporting older adults. By involving care workers, we can create more inclusive and practical care-based technologies that address the challenges faced by both older adults and their caregivers. Moreover, this collaborative approach ensures that technological advancements do not come at the expense of frontline care workers, reinforcing the need to value their labor rather than further marginalizing it.

Amplify Care Workers' Agency in Defining and Navigating the Work Boundaries

Consistent with previous research [29,60], this study demonstrates that care workers' job roles are often ambiguously defined and shaped by the evolving needs of residents. Then, the added responsibility of providing tech support further complicated their work [29,30]. While some participants attempted to distinguish their caregiving duties from tech support, their ongoing assistance with residents' technology needs blurred these boundaries over time. This role expansion, driven by their dedication to resident well-being, contributed to an increased workload and emotional exhaustion, aligning with prior research that links caregiving to burnout [61].

However, given the dynamic nature of person-centered care in assisted living, rigidly defining caregiving responsibilities may not be the most effective approach. Indeed, a degree of flexibility is beneficial, as it allows care workers to respond adaptively to residents' needs while reducing workplace strain [60,61]. Therefore, rather than imposing strict role definitions, we emphasize the importance of empowering care workers to define their own work boundaries within a supportive environment [60]. In practice, encouraging open discussions with peers and supervisors will help establish and adjust these boundaries as needed. Lastly, we recommend that employers acknowledge the additional labor associated with less-recognized tasks, such as tech support, and create spaces for care workers to reflect on these responsibilities. Practical steps include offering paid workshops, professional development opportunities, and structured communication channels to foster collaboration and ensure that care workers feel supported in balancing their evolving responsibilities while maintaining their well-being.

Limitations

Our findings must be considered in light of several limitations. First, our sample consisted mainly of younger care workers who did not report experiencing tech-related difficulties while assisting residents. Given that the US caretaking workforce is aging, with a median age of 47 years [62], future research should examine how age-related factors influence care workers' ability to provide tech support. Second, although we did not find differences in experiences across job titles, this may be because our analysis primarily focused on general care-support tasks that remain consistent across caregiving roles. Moreover, the small sample size within each job category might have limited

XSL•FO
RenderX

the feasibility of comparative analysis. Future studies should include a larger sample to explore potential variations in experiences across different caregiving positions. Third, all participants were based in the United States, meaning the findings primarily reflect Western perspectives. Cross-cultural comparisons can provide a more comprehensive understanding of how care workers use technology support. Fourth, the study relied on self-reported experiences, which may be subject to bias. Participants might have underreported difficulties or overemphasized their ability to provide tech support, potentially skewing the findings. Future research could incorporate diverse methods to capture a more objective understanding of the challenges faced by care workers.

Conclusions

Given the rise in technology adoption among older adults and in long-term residential facilities, this study explored the perspectives and experiences of care workers in providing technology support to residents. We identified the nuanced physical and emotional labor involved in technology support, which has become a core yet often unrecognized aspect of caregiving. Additionally, the varying perspectives of care workers on their technology support roles highlight ongoing tensions in work expectations within long-term care. Based on these findings, we advocate for greater recognition of care workers' efforts through recommendations for further research, improved workplace policies, and enhanced program design in long-term care.

Acknowledgments

The research would not have been possible without our participants' contributions. We deeply appreciate the time they took to talk with us and their valuable insights and perspectives.

Data Availability

Data will be made available on reasonable request.

Funding

No external financial support or grants were received from any public, commercial, or not-for-profit entities for the research, authorship, or publication of this article.

Authors' Contributions

YW led the data analysis and manuscript writing and editing, and assisted with project administration. NR led the data collection and assisted with data analysis. SK oversaw the overall project administration, assisted with data analysis, and participated in manuscript writing and editing.

Abstract

Background: Subjective cognitive decline (SCD) typically refers to self- or informant-reported decline in cognition despite the absence of objective impairment on standardized testing. Older adults with documented normal cognitive test performance provide a pragmatic anchor cohort for electronic health record (EHR)–based SCD phenotyping. However, cognitive concerns are primarily recorded in unstructured notes and are inconsistently documented, making it unclear how often and in whom concerns are captured in routine care.

Objective: This study aims to operationalize EHR-based SCD phenotyping in an objectively normal-testing cohort using a large language model (LLM)–based natural language processing approach and to examine the frequency and clinical and sociodemographic correlates of cognitive concern documentation.

Methods: We conducted an EHR-based observational study of patients aged 65 years or older with a first normal cognitive test recorded in EHR flowsheets between January 2019 and April 2024 in a large health care system. We developed and iteratively refined a 2-stage LLM-based natural language processing pipeline to identify documented cognitive concerns in unstructured notes during the 12 months prior to the index date, and evaluated performance against manual review. We quantified the frequency of documented concerns within this normal-testing cohort and used multivariable logistic regression to assess associations with sociodemographic factors (age, marital status, insurance, and neighborhood Area Deprivation Index), sequentially adjusting for clinical comorbidities and relevant medications.

Results: Among 15,750 older adults with normal cognitive test scores, 13.8% (n=2175) had at least 1 documented cognitive concern in the prior year, captured in 1.2% (7394/605,177) of notes. On manual validation, the 2-stage pipeline (Med42-v2-8B screening followed by GPT-4o confirmation) achieved a sensitivity of 0.957, positive predictive value of 0.935, specificity of 0.985, and F_1-score of 0.945 for cognitive concern identification. Documentation was more likely in older individuals, those with commercial (vs Medicare) insurance, and those with neurological and psychiatric conditions. In fully adjusted models, Parkinson disease (adjusted odds ratio [aOR] 5.29, 95% CI 3.60 - 7.77), traumatic brain injury (aOR 4.63, 95% CI 3.15 - 6.81), stroke or transient ischemic attack (aOR 3.46, 95% CI 3.15 - 4.18), epilepsy (aOR 2.52, 95% CI 1.83 - 3.49), depression (aOR 1.54, 95% CI 1.36 - 1.75), and excessive alcohol use (aOR 1.48, 95% CI 1.06 - 2.06) were among the strongest correlates of cognitive concern documentation. In contrast, obesity (aOR 0.73, 95% CI 0.65 - 0.82), hyperlipidemia (aOR 0.59, 95% CI 0.51 - 0.67), and residence in more deprived neighborhoods (higher Area Deprivation Index) were associated with lower odds of documented cognitive concerns.

Conclusions: A 2-stage LLM pipeline enabled accurate identification of documented cognitive concerns consistent with SCD among older adults with normal cognitive testing. Documentation was uncommon and selectively captured by clinical and sociodemographic factors, with implications for equity and the validity of EHR-based phenotypes.

large language model; cognitive concern; subjective cognitive decline; electronic health records; documentation

Introduction

Given emerging therapies for Alzheimer disease (AD), early detection is increasingly critical to ensure interventions are delivered at the most beneficial stage of the disease trajectory. Subjective cognitive decline (SCD) is characterized by self- or partner-reported concerns about memory or other cognitive functions despite normal performance on standardized cognitive tests [1]. SCD represents one of the earliest stages at which cognitive changes become noticeable to patients, family members, or clinicians, often preceding measurable impairment, such as mild cognitive impairment (MCI) [2,3]. Importantly, longitudinal meta-analyses show that SCD is associated with approximately 2-fold higher risk of subsequent dementia and elevated risk of incident MCI, supporting SCD as a clinically meaningful risk marker rather than a universally benign complaint [4,5]. As such, recognizing SCD in clinical settings provides a valuable window of opportunity for early intervention, risk reduction, and enrollment in clinical trials targeting preclinical AD [6].

However, SCD remains underrecognized in routine care and is difficult to identify systematically in electronic health records (EHRs). Unlike MCI or dementia, SCD lacks a standardized diagnostic code, limiting scalable identification for clinical screening and research. In practice, documented cognitive concerns and objective testing are often misaligned: many individuals never undergo formal cognitive testing, while others are tested without any documented concerns [7,8]. Among individuals with normal test scores, the presence vs absence of documented cognitive concerns provides a clinically relevant contrast for examining how early symptoms are recognized and recorded. Characterizing variation in documentation by clinical and sociodemographic characteristics is critical for equitable early detection and for valid EHR-based cognitive aging research. Emerging evidence suggests that recognition, reporting, and clinical documentation of cognitive concerns may vary across socioeconomic, racial or ethnic, and health care access contexts, potentially introducing bias into EHR-based phenotyping and delaying identification of individuals at risk for future cognitive decline [9]. Individuals from disadvantaged communities may also face barriers to early evaluation and specialty memory care, further affecting how cognitive concerns are documented in routine clinical practice [10,11].

Cognitive concerns are typically embedded in free-text clinical notes rather than structured fields, making automated detection challenging, particularly given the wide variation in language describing cognitive concerns among clinicians, patients, and family members [12,13]. Recent advances in large language models (LLMs) present an opportunity to overcome these barriers. LLMs have significantly enhanced the depth, accuracy, and efficiency of natural language processing (NLP) for automated information extraction from EHR data. Unlike traditional rule-based NLP tools that rely on predefined patterns and keywords, LLMs are trained on vast text corpora to learn statistical relationships in language, enabling them to capture context, nuance, and phrasing variation beyond the capabilities of rule-based systems. LLMs can analyze unstructured notes at scale, searching for nuanced mentions of cognitive concerns that might otherwise go unnoticed. Although our prior studies have used deep learning and LLMs to detect broad indicators of cognitive decline in EHRs [14], few studies have focused on SCD, and fewer have compared individuals with and without SCD among those with normal cognitive test performance [12,13]. Moreover, factors that may affect the documentation of subjective concerns, such as comorbidities, medication use, and sociodemographic characteristics, remain incompletely understood.

In the present study, we leveraged LLM and EHR data to systematically identify SCD among individuals with normal cognitive test performance. The aims of this study were to (1) develop and evaluate a scalable LLM-based approach for identifying documented SCD from unstructured clinical notes and (2) compare sociodemographic, clinical, and medication characteristics of individuals with and without documented SCD. We hypothesized that individuals with documented SCD would differ in clinical and sociodemographic profile despite normal cognitive testing.

Methods

Data Sources

We used EHR data from Mass General Brigham (MGB), a large integrated health care system that includes Massachusetts General Hospital, Brigham Women's Hospital, and affiliated community hospitals in Massachusetts. Data were obtained from 2 enterprise EHR data repositories, including the Research Patient Data Registry (RPDR) and the Enterprise Data Warehouse (EDW), spanning from January 1, 2015, to April 10, 2024.

Ethical Considerations

The study was approved by the MGB Institutional Review Board. Cognitive assessment data were collected as part of routine clinical care and obtained retrospectively from the EHR. The study team did not administer any cognitive assessment instruments for research purposes, and licensing information was not available through the EHR repositories.

Study Sample

We defined presumed SCD as the presence of documented cognitive concerns among individuals with normal cognitive test scores. Individuals were initially identified based on cognitive assessments recorded in EHR flowsheets between January 1, 2015, and April 10, 2024. Cognitive assessments included the Mini-Cog, Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA), Saint Louis University Mental Status (SLUMS) examination, and the Ascertain Dementia 8-Item Informant Questionnaire (AD8) dementia screening interview. When all MMSE items were documented, but the total score was missing, we calculated the

XSL•FO
RenderX

total by summing item scores. Cognitive assessments without a total score were excluded, including partly administered tests due to time constraints.

To establish a baseline of normal cognition, we defined the index data as each individual's first cognitive assessment occurring between January 1, 2019, and April 10, 2024. The period from January 1, 2015, to December 31, 2018, served as a lookback window to identify prior cognitive assessments. Individuals with any cognitive assessment recorded during this earlier period were excluded to ensure that the index assessment represented the first observed cognitive assessment in the EHR during the study period. We further restricted the cohort to individuals aged ≥65 years at the time of their first assessment to focus on age groups most relevant to AD and related dementias.

We narrowed down the study cohort to include individuals with normal cognitive test scores based on established cutoff criteria: Mini-Cog: 4‐5, MMSE: ≥26, MoCA: ≥26, SLUMS: ≥27, AD8: 0‐1. For the remaining individuals, we extracted all their clinical notes within 1 year prior to the initial cognitive test from MGB's EHR databases. Individuals who did not have notes available in the MGB EHR were excluded. We further excluded individuals who had a prior history of cognitive decline, related diagnosis (eg, MCI or dementia) prior to the index date. Specifically, we excluded individuals with evidence of prior cognitive decline or related diagnoses before the index date. Prior history was identified using structured EHR data extracted from RPDR and EDW, including diagnosis records and problem list entries, based on relevant *International Classification of Diseases* (*ICD*) codes for dementia, MCI, AD, and related cognitive disorders documented before the index cognitive assessment date. In addition, note-derived cognitive concern information (see *LLM-Based Cognitive Concern Extraction* section) was used to identify prior patient-related cognitive decline documentation, including cognitive assessments, MCI, and dementia documentation in the notes. Individuals meeting any of these criteria before the index date were excluded from the final cohort.

Dependent Variable: Cognitive Concerns

The primary dependent variable was the presence of cognitive concerns within one year prior to the first normal cognitive assessment, defined as a binary indicator (yes/no). Given that cognitive concerns in the early stages of cognitive decline were often documented in free-text, we used LLMs to identify and extract cognitive concerns from clinical notes (described in the *LLM-Based Cognitive Concern Extraction* section).

LLM-Based Cognitive Concern Extraction

We used a combination of open-source and commercial LLMs to extract cognitive concerns from clinical notes. Notes were first split into smaller sections of up to 300 words. For each section, the model was prompted to (1) indicate whether a cognitive concern is mentioned (yes/no) and (2) extract the relevant text verbatim (see Table S1 in Multimedia Appendix 1 for prompts). As the open-source model, we selected Med42-v2-8B, a Llama 3-based model fine-tuned on clinical data, which enables efficient processing of large volumes of notes at minimal cost [15]. The prompt of this model was optimized for high sensitivity to exclude cases that clearly lacked cognitive concerns while capturing as many potential positives as possible. As the commercial model, we deployed OpenAI GPT-4o in a Health Insurance Portability and Accountability Act (HIPAA)-compliant Microsoft Azure environment. We adopted a 2-stage pipeline to balance scalability and accuracy. In iterative prompt development, Med42-v2-8B was effective as a high-sensitivity screening model but produced more false positives, including occasional overinterpretation or hallucination of cognitive concerns. More restrictive prompts improved precision but reduced sensitivity and did not fully eliminate these errors. Therefore, Med42-v2-8B was used to screen out notes unlikely to contain cognitive concerns, and GPT-4o was applied only to Med42-v2-8B-positive notes to improve confirmation accuracy while reducing computational cost.

Evaluation of LLMs in Cognitive Concern Extraction

To evaluate cognitive concern identification, we constructed an evaluation set of 500 note chunks using stratified sampling by model-predicted class. Because the prevalence of cognitive concerns in the full corpus was low, we randomly sampled note chunks classified as positive and negative by the Med42-v2-8B model at a 3:1 ratio to enrich positive cases. Two annotators (JT and SV) independently reviewed an initial subset of 100 note chunks to assess interannotator agreement for binary cognitive concern identification using Cohen κ. After substantial agreement was achieved (κ=0.70; overall agreement=90%), the annotators independently reviewed the remaining note chunks, with each annotator reviewing an additional 200 chunks. Discrepancies between annotators were adjudicated by a cognitive neurologist (GAM) to establish the reference standard. In addition, selected discordant cases between LLM predictions and reference labels were reviewed by domain experts to better characterize sources of disagreement and model errors. We then compared the LLM outputs with this reference standard and assessed performance using sensitivity, specificity, positive predictive value (PPV), and F_1 score (the harmonized score of sensitivity and PPV).

Covariates

Individual-level covariates included age (in years), patient-reported sex, race or ethnicity, marital status, education level, language preference, and insurance type. Neighborhood deprivation was assessed using the 2023 Area Deprivation Index (ADI) [16]. For each individual, we derived a 9-digit ZIP code from the residential address and ZIP code, then linked this to the ADI database to obtain the national ADI percentile. Individuals were categorized into three groups based on their national ADI percentile: low (1st-20th percentile), medium (21st-40th percentile), and high (41st-100th percentile).

To account for documentation opportunity, we calculated the number of clinical notes in the year prior to the index date. To capture comorbidity burden, we identified relevant medical conditions across domains like neurological, cardiovascular, cerebrovascular, metabolic, endocrine, psychiatric, autoimmune, infectious diseases, and sensory impairment (eg, hearing and visual loss), as well as lifestyle factors (eg, smoking) [17].

XSL•FO
RenderX

Conditions were identified using rule-based phenotyping algorithms tailored to individual conditions (see Table S2 in Multimedia Appendix 1). We also calculated the Charlson Comorbidity Index using *ICD* diagnosis codes recorded in the 2 years prior to the index date.

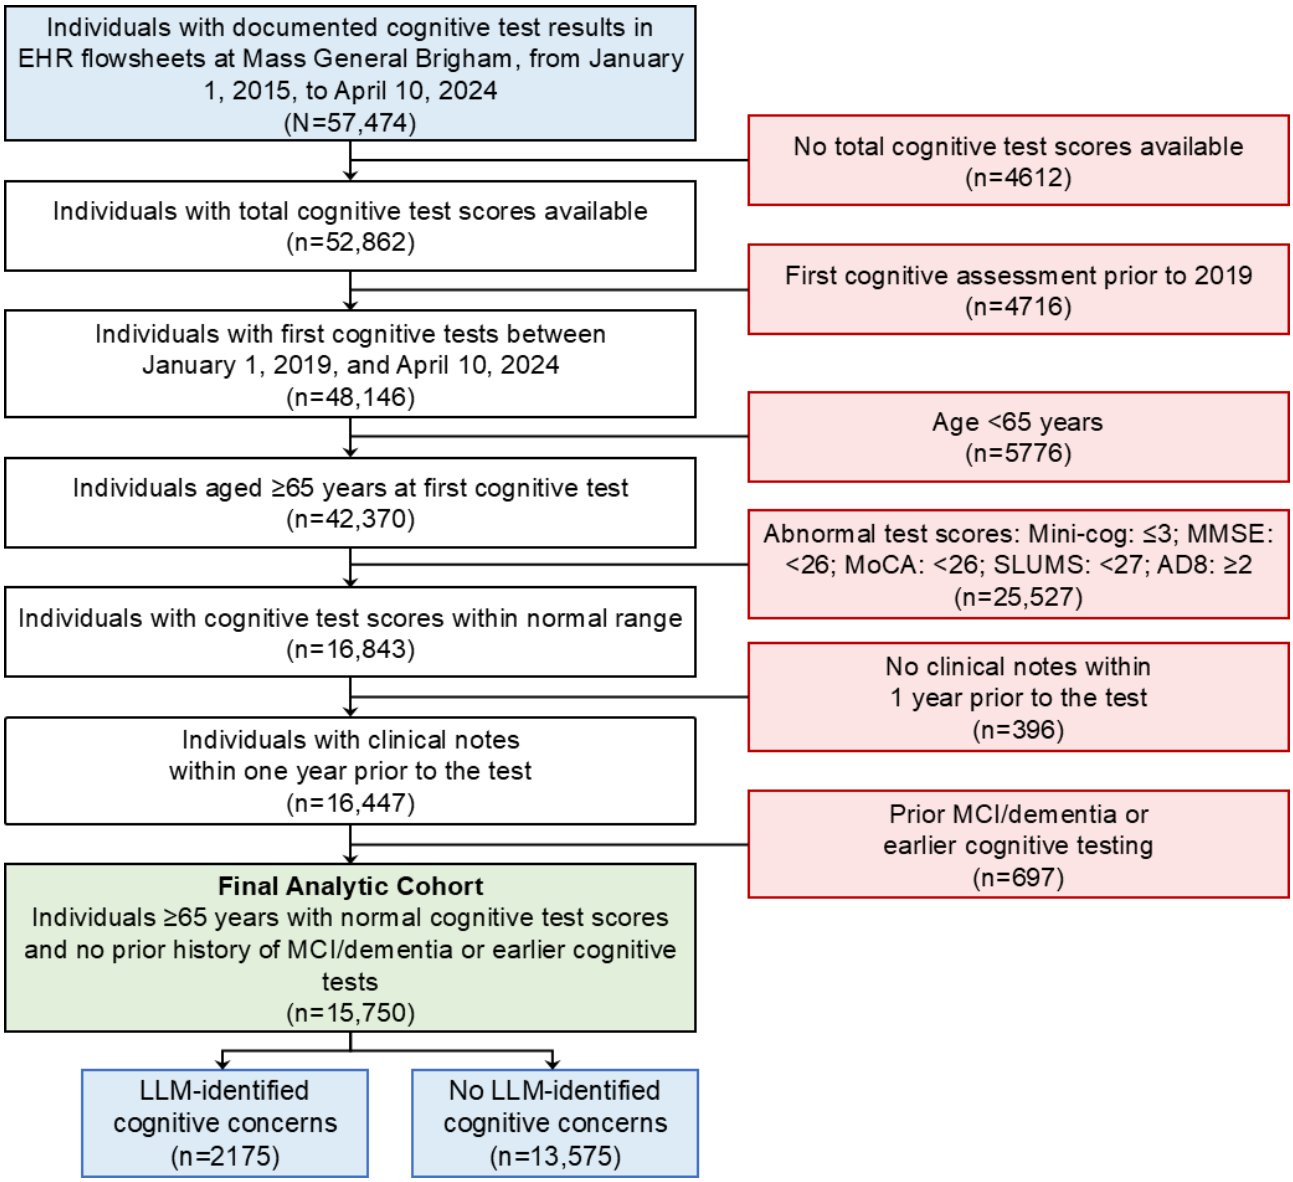
In addition, we reviewed the medication history within 1 year prior to the cognitive tests based on prescription records. Medications were grouped into categories based on their potential cognitive effects, including anticholinergic medications, benzodiazepines and sedative-hypnotics, antidepressants, antipsychotics, antiepileptics, opioids, and other medications of concern (eg, beta-blockers, corticosteroids, chemotherapy agents, and H2-receptor antagonists; Table S3 in Multimedia Appendix 1). Each class includes medications known to impair cognition through mechanisms such as anticholinergic burden, GABAergic activity, sedative properties, or blood-brain barrier penetration.

Statistical Analysis

We compared demographic and clinical characteristics between individuals with and without documented cognitive concerns. For continuous variables, we used 2-tailed *t* tests; for categorical variables, we used the chi-square tests or Fisher exact tests. To identify factors associated with documented cognitive concerns, we fitted multivariable logistic regression models with cognitive concern (yes/no) as the dependent variable. For the number of clinical notes in the year prior to the index date, we modeled it as a log2-transformed variable to address right-skew and facilitate interpretation (ie, per doubling of note count). Three nested models were constructed: Model 1 included sociodemographic variables and log2-transformed note count; model 2 additionally included clinical conditions (eg, Charlson Comorbidity Index and selected comorbidities); and model 3 further included medication classes based on medication prescriptions (eg, anticholinergics and antidepressants). Variables with $P<.05$ in univariate analyses were considered for inclusion in multivariable models. We reported crude and adjusted odds ratios (aORs) with 95% CIs. All analyses were conducted in R (version 4.4.1; R Foundation for Statistical Computing) using RStudio.

Results

We identified 57,474 individuals with cognitive assessments documented in EHR flowsheets (Figure 1), of whom 52,862 had total scores available. We then restricted the cohort to 48,146 individuals whose first cognitive test occurred between January 1, 2019, and April 10, 2024, and further to 42,370 individuals aged 65 years or older. Limiting the cohort to those with normal cognitive scores yielded 16,477 individuals. After excluding individuals with prior cognitive decline or earlier cognitive assessments, 15,750 individuals met all inclusion and exclusion criteria.



Among the final study cohort, 13.8% (n=2175) had a documented cognitive concern in the prior year. The cognitive concerns were identified from 7395 of 605,177 (1.2%) notes recorded in the year before the first normal cognitive test. The Med42-v2-8B model showed high sensitivity (97.8%) but moderate PPV (64.7%) for identifying cognitive concerns (Table S4 in Multimedia Appendix 1). When GPT-4o was used to reprocess all positive cases identified by the Med42-v2-8B, sensitivity remained high (95.7%) while PPV increased to 93.5% and specificity to 98.5%, improving the F_1-score from 0.779 to 0.945 and yielding more balanced performance across all metrics. We manually reviewed false positives and false negatives from the final pipeline. Most false positives reflected ambiguous or inferential mentions, often related to delirium or other acute conditions, whereas false negatives typically involved very subtle or indirect references to cognitive symptoms (eg, mentions of a “memory unit”) and institutional abbreviations or shorthand.

Most index cognitive assessments occurred in outpatient primary care settings (14,427/15,750, 91.6%), followed by hospital or rehabilitation settings (460/15,750, 2.9%) and outpatient neurology or geriatrics settings (440/15,750, 2.8%; Table S5 in Multimedia Appendix 1). Cognitive concern documentation was distributed across multiple clinical settings, including hospital or rehabilitation settings (574/2175, 26.4% patients), outpatient primary care (1045/2175, 48.0%), neurology or geriatrics (257/2175, 11.8%), and medical specialties (215/2175, 9.9%; Table S6 in Multimedia Appendix 1). These findings suggest that cognitive concerns were captured across diverse clinical contexts rather than solely in primary care or neurology encounters. Detailed score distributions by cognitive test are provided in Table S7 in Multimedia Appendix 1.

Among these 15,750 individuals, 15,038 (95.5%) were White, only 228 (1.4%) identified as Hispanic, and 9651 (61.3%) were female (Table 1). Most were married (n=10,095, 64%). More than half of the cohort (n=8115, 51.5%) had a college education or higher, and 97.9% (n=15,426) reported English as their preferred language. The majority (n=12,202, 77.5%) had Medicare as their insurance, while 3031 (19.2%) had commercial insurance. In terms of neighborhood socioeconomic status, 8278 (52.6%) lived in the least deprived area with national ADI≤20.

[d]MMSE: Mini-Mental State Examination.

[e]SLUMS: Saint Louis University Mental Status Examination.

[f]AD8: Ascertain Dementia 8-Item Informant Questionnaire

[g]Of these notes, 7394 had mention of cognitive concerns.

[h]Not applicable.

Individuals with cognitive concerns were older (mean 75.0, SD 6.9 y vs 73.2, SD 6.3 y), less likely to be married (1267/2175, 58.3% vs 8828/13,575, 65%), more likely to have commercial insurance (484/2175, 22.3% vs 2547/13,575, 18.8%), and more likely to live in less deprived neighborhoods (low ADI: 1207/2175, 55.5% vs 7071/13,575, 52.1%; high ADI: 198/2175, 9.1% vs 1623/13,575, 12.0%). Sex, race, ethnicity, and education distribution were similar between groups with and without documented cognitive concerns. Consistent with these patterns, unadjusted analyses showed higher odds of concern documentation with older age (crude odds ratio [OR] 1.51 per 10-y increase, 95% CI 1.41 - 1.61) and commercial insurance (vs Medicare; OR 1.25, 95% CI 1.12 - 1.40), and lower odds with being married (OR 0.75, 95% CI 0.68 - 0.82) and with greater neighborhood deprivation (medium vs low ADI: OR 0.88, 95% CI 0.79 - 0.97; high vs low ADI: OR 0.71, 95% CI 0.61 - 0.84; Table S8 in Multimedia Appendix 1).

Cognitive assessment type differed significantly by cognitive concern status (*P*<.001). Individuals without cognitive concerns were more likely to undergo the Mini-Cog (12,876/13,575, 94.9% vs 1402/2175, 64.5%), whereas those with cognitive concerns were more frequently assessed with the MoCA (566/2175, 26% vs 338/13,575, 2.5%) or MMSE (183/2175, 8.4% vs 355/13,575, 2.6%). Mini-Cog scores were marginally lower in the cognitive concern group (4.7 vs 4.8, *P*<.001). Individuals with cognitive concerns also had a substantially higher number of clinical notes per individual (median 54, IQR 28 - 102 vs median 22, IQR 10 - 41; *P*<.001).

Compared with individuals without cognitive concerns, those with cognitive concerns had a markedly higher frequency of several neurological conditions (stroke or transient ischemic attack [TIA], Parkinson disease, traumatic brain injury [TBI], and epilepsy) and cardiovascular conditions (hypertension, coronary artery disease, atrial fibrillation, and heart failure), whereas obesity and hyperlipidemia were slightly less common (Table 2). In crude analysis, the strongest associations with cognitive concern documentation were observed for Parkinson disease (OR 6.13, 95% CI 4.37 - 8.60), TBI (OR 7.75, 95% CI 5.55 - 10.85), stroke or TIA (OR 5.00, 95% CI 4.23 - 5.90), and epilepsy (OR 3.70, 95% CI 2.78 - 4.90), with additional positive associations for depression (OR 2.53, 95% CI 2.29 - 2.79), excessive alcohol use (OR 2.36, 95% CI 1.76 - 3.12), and anxiety (OR 1.82, 95% CI 1.65 - 2.01; Table S5 in Multimedia Appendix 1). Conversely, obesity (OR 0.83, 95% CI 0.75 - 0.92) and hyperlipidemia (OR 0.76, 95% CI 0.68 - 0.84) were associated with lower odds, indicating cognitive concerns were less likely to be documented in patients with these comorbidities.

[d]CCI: Charlson Comorbidity Index.

Individuals with subjective cognitive concerns had greater exposure to medications with potential cognitive effects than those without concerns (Table 3). Across most major drug classes, including anticholinergics, benzodiazepines and other sedative-hypnotics, antidepressants, antiepileptics, opioids, and other medications of concern such as H2-receptor antagonists, beta-blockers, corticosteroids, and chemotherapy agents, individuals with cognitive concerns were significantly more likely to have at least one prescription. Subclasses that were rarely prescribed (eg, barbiturates and antiparkinsonian anticholinergics) showed no significant differences between groups.

In multivariable models that are sequentially adjusted for sociodemographic and documentation opportunity factors (model 1), then additionally for clinical comorbidities (model 2), and finally for relevant medication prescriptions (model 3), most associations were attenuated but remained significant (Multimedia Appendix 1 Table S5). Figure 2 shows the aORs and 95% CIs from the fully adjusted model (model 3) across sociodemographics, documentation opportunity, clinical comorbidities, and medication classes. In the fully adjusted model (model 3), among the sociodemographics factors, older age (aOR 1.27 per 10-y increase, 95% CI 1.17 - 1.37) and commercial insurance (vs Medicare; aOR 1.35, 95% CI

XSL•FO
RenderX

1.19 - 1.53) remained strongly associated with cognitive concern documentation, whereas higher neighborhood deprivation was attenuated (medium vs low ADI: aOR 0.87, 95% CI 0.78 - 0.98; high vs low ADI: aOR 0.79, 95% CI 0.66 - 0.95). As expected, the number of notes was strongly associated with the documentation of cognitive concerns across all models. Neurological conditions showed the strongest associations, including Parkinson disease (aOR 5.29, 95% CI 3.60 - 7.77), TBI (aOR 4.63, 95% CI 3.15 - 6.81), stroke or TIA (aOR 3.46, 95% CI 2.86 - 4.18), and epilepsy (aOR 2.52, 95% CI 1.83 - 3.49). Depression (aOR 1.54, 95% CI 1.36 - 1.75) and excessive alcohol use (aOR 1.48, 95% CI 1.06 - 2.06) also remained significant. Obesity (aOR 0.73, 95% CI 0.65 - 0.82) and hyperlipidemia (aOR 0.59, 95% CI 0.51 - 0.67) were associated with lower odds of documentation.

Figure 2. Factors associated with documentation of cognitive concerns in cognitively unimpaired older adults (N=15,750): (A) sociodemographics, (B) documentation opportunity, (C) clinical comorbidities, and (D) medications. GI: gastrointestinal; TIA: transient ischemic attack.

Discussion

Principal Findings

In this study, we examined how cognitive concerns are documented in routine clinical care among older adults with normal cognitive test scores. Using EHR data from a large cohort of individuals aged 65 years or older with an initial normal cognitive assessment, we applied an LLM-based NLP pipeline to identify cognitive concerns from clinical notes in the year prior to testing and used multivariable logistic regression to evaluate the association of cognitive concerns with sociodemographic and clinical factors. We found that cognitive concerns were documented in a minority of individuals and within a very small fraction of notes. Several neurologic (Parkinson disease, TBI, stroke or TIA, and epilepsy) and psychiatric (depression, anxiety, and excessive alcohol use) conditions were associated with higher odds of documentation of cognitive concerns, whereas some metabolic conditions (hyperlipidemia and obesity) and living in more deprived neighborhoods (higher ADI) were associated with lower odds. These associations largely persisted after adjustment for sociodemographic factors, documentation opportunity, comorbidities, and relevant medications. By linking structured cognitive test scores with concerns extracted from unstructured notes at scale, this work provides novel insights into how early cognitive symptoms are selectively recognized and recorded in the EHR, with important implications for both clinical care and EHR-based phenotyping.

The frequency of documented cognitive concerns prior to a normal test was low (13.8% overall). Documentation of cognitive concerns was even less common for individuals assessed with the Mini-Cog, which is a very brief cognitive screening test, than for those assessed with other instruments (MoCA, MMSE, SLUMS, and AD8), most of which are longer cognitive screening tests. This suggests that many cognitive tests are performed without an explicitly documented concern, which may reflect routine screening, clinician-initiated evaluation, or underdocumentation of symptoms. Additionally, it suggests that for individuals with cognitive concerns, a longer cognitive screening test is usually used.

Among sociodemographic factors, we observed clear patterns in documentation of cognitive concerns. Older age was associated with higher odds of documentation, consistent with greater symptom burden and increased clinician vigilance in older adults. Individuals with commercial insurance remained more likely to have cognitive concerns documented than those with Medicare, even in the fully adjusted model. This pattern is consistent with prior work showing that privately insured individuals are more likely to receive preventive services and certain types of outpatient care than publicly insured individuals, which may increase opportunities for patients to report and clinicians to document cognitive concerns [18]. In addition, our finding that higher neighborhood deprivation was associated with lower odds of documented cognitive concerns contrasts with prior work linking more disadvantaged neighborhoods to a higher risk of cognitive decline and dementia [19,20]. However, this discrepancy may reflect differential recognition or documentation of early cognitive symptoms in routine care rather than a truly lower burden of cognitive problems. Individuals from more disadvantaged communities may be less likely to access evaluation at earlier stages and may present for care at later stages of cognitive impairment, when deficits are more apparent [10,11]. Thus, lower documentation of subjective concerns among residents of high-ADI neighborhoods may indicate delayed help-seeking, competing clinical priorities, and fewer opportunities for symptom elicitation and recording [10].

Clinical comorbidities showed a coherent pattern. Neurological conditions, such as Parkinson disease, TBI, stroke or TIA, and epilepsy, had the highest adjusted odds, indicating that clinicians are particularly likely to document cognitive concerns when clear neurologic risk factors are present. Depression and excessive alcohol use were also associated with higher odds, likely reflecting overlapping symptoms (eg, memory complaints and concentration) with cognitive concerns and more frequent discussion of cognition in mental health-focused encounters. Hearing impairment showed a modest but consistent association, which may reflect either shared vulnerability or clinical "diagnostic uncertainty," as hearing-related communication difficulties can prompt concerns about cognition. In contrast, obesity and hyperlipidemia were linked to lower odds of documentation, which may reflect competing clinical priorities, underrecognition of cognitive issues in individuals seen primarily for metabolic disease, and residual confounding, and should be interpreted cautiously pending further study. Other cardiovascular and systemic conditions, including coronary artery disease, showed small positive associations, while several conditions (eg, hypertension and type 2 diabetes) were not independently associated after adjustment. The association for anxiety was attenuated after medication adjustment and became borderline, suggesting the crude comorbidity association may be partly explained by medication use.

Individuals with documented cognitive concerns were also more likely to receive medications with potential cognitive effects, including anticholinergics, benzodiazepines and sedative-hypnotics, antidepressants, antiepileptics, and opioids. These associations may reflect several overlapping mechanisms, including medication-related cognitive symptoms, greater psychiatric and neurological comorbidity burden, and increased clinical attention to cognition among medically complex patients. Because this study focused on documentation of cognitive concerns rather than causal cognitive effects, these findings should not be interpreted as evidence that these medications directly caused cognitive decline. Rather, they highlight the complex clinical context in which cognitive concerns are elicited and documented in routine care.

Strengths

This study is among the first to use LLMs and a large, well-defined cohort of older adults with normal cognitive test scores to examine patterns of subjective cognitive concern documentation before clear cognitive impairment or diagnosed dementia. We applied a 2-tier LLM-based NLP pipeline with high sensitivity and positive predictive value to identify cognitive concerns from unstructured notes, demonstrating the feasibility of scalable, accurate phenotyping beyond structured

XSL•FO
RenderX

data alone. We also integrated rich EHR data, including sociodemographic characteristics, neighborhood deprivation (ADI), detailed comorbidities, and medication prescriptions, enabling a nuanced examination of how clinical and contextual factors jointly affect documentation of SCD. By estimating multiple adjusted models and explicitly focusing on documentation of cognitive concerns rather than test scores or diagnosis, our work offers a novel perspective on how early cognitive symptoms are recognized and recorded in routine care and how this may shape EHR-based research and clinical tools.

Limitations

This study has several limitations. First, we identified the cohort using cognitive test results recorded in flowsheets; individuals whose assessments were documented only in narrative notes may have been missed, introducing selection bias. Second, "normal" cognition was defined using standard screening cutoffs without adjustments. Because these instruments differ in sensitivity and can be biased by educational and sociodemographic factors, subtle impairment may have been misclassified as normal. Third, cognitive concern status may have been misclassified, potentially underestimating differences between groups: we relied on documented concerns, so concerns that were not elicited, reported, or recorded could have been misclassified as "no concern." In addition, we restricted NLP extraction to notes within 1 year before the first qualifying cognitive test, potentially missing concerns documented earlier or outside this window. Because cognitive concerns could be documented repeatedly across multiple encounters and specialties over time, the current study was not designed to evaluate longitudinal care pathways or delays between initial concern documentation and cognitive testing. We also did not explicitly model the temporal ordering of neurological conditions, medication exposure, cognitive concern documentation, and cognitive testing. Some neurological diagnoses and medication exposures may have preceded concern documentation, whereas others may have occurred afterward as part of ongoing clinical evaluation and management. Therefore, observed associations should be interpreted as correlates of cognitive concern documentation rather than evidence regarding causal or prognostic sequencing. Future longitudinal studies should evaluate whether EHR-documented cognitive concerns provide incremental predictive value beyond established neurological and clinical risk factors, particularly when concern documentation precedes the onset or recognition of these conditions. Although our two-tier LLM-based pipeline showed high sensitivity and PPV in cognitive concern extraction, some misclassification is inevitable. Because GPT-4o was applied only to Med42-v2-8B positive note chunks, true positive cases missed at the first screening stage could not be recovered in the second stage. Exploratory analysis identified 2 additional reference-standard positive cases among Med42-v2-8B negative cases, suggesting that direct application of GPT-4o to all note chunks could further improve sensitivity if computational resources permit. However, the staged design substantially reduced computational cost and token usage while maintaining strong overall performance. Finally, this single-health-system, cross-sectional EHR study may have limited generalizability and cannot support causal inference or assessment of subsequent cognitive decline and dementia.

Conclusions

This study used EHR data and LLMs to identify and characterize SCD, showing that cognitive concerns are infrequently documented among older adults with normal cognitive test scores. Documentation was more common in those with neurological, psychiatric, and substance-use conditions, but less common among individuals living in more deprived neighborhoods and those with certain metabolic conditions. These findings suggest inconsistent recognition and documentation of early symptoms, with implications for equity and for EHR-based phenotypes and prediction models. Future work will evaluate whether baseline SCD predicts subsequent cognitive decline, to support more consistent, data-driven early detection and management.

Abstract

Background: Early mortality after long-term care facility (LTCF) admission is common; yet, prognostic tools are often derived from Western minimum dataset-based cohorts or require hospital electronic health record linkages that are unavailable at intake in many LTCFs. There is also limited evidence on explainable, admission-feasible machine learning–based prognostication in Asian LTCF settings.

Objective: The aim of the study is to develop and temporally externally validate an interpretable machine learning model for predicting 6-month all-cause mortality among older adults newly admitted to LTCFs in Taiwan using routinely collected LTCF assessment data.

Methods: We conducted a retrospective cohort study using the JUBO Long-Term Care Database, a nationwide private administrative registry covering 636 LTCFs (37.4% of the national LTCFs) in Taiwan. We included residents with first-time LTCF admission and prespecified nonoverlapping cohorts for temporal validation: development (January 1, 2020, to December 31, 2023; n=23,901) and external validation (January 1 to December 31, 2024; n=6216). The outcome measure was death within 180 days of admission. We compared a nonlinear ensemble model (hybrid of extreme gradient boosting and random forest [HybridXGBRF]) with 7 other algorithms, including tree-based and linear benchmarks. Discrimination (area under the receiver operating characteristic curve [AUROC]), classification metrics (accuracy, precision, recall, and F_1), and calibration (Brier score and calibration plots) were assessed. Model interpretability was examined using Shapley Additive Explanations.

Results: In the development cohort, 5272 of 23,901 (22.1%) residents died within 180 days. In the 2024 temporal validation cohort, 1781 of 6216 (28.7%) residents died. In internal cross-validation, HybridXGBRF had the highest AUROC among the evaluated models (0.89, 95% CI 0.88 - 0.89). In temporal validation, HybridXGBRF maintained strong discrimination (AUROC 0.90, 95% CI 0.89 - 0.91), with an accuracy of 0.85 and an F_1-score of 0.68. Calibration plots indicated close agreement between predicted and observed risks across most probability ranges, with mild divergences at higher predicted risks. Shapley Additive Explanations analysis identified frequent hospitalizations within 6 months, activities of daily living impairment, and weight loss as influential predictors. The model showed stable AUROC across sex and age strata (0.89 - 0.90) and maintained high discrimination among residents with improving activities of daily living scores (AUROC 0.91, 95% CI 0.90 - 0.92).

Conclusions: An interpretable machine learning model using routinely collected Taiwanese LTCF assessment data achieved strong discrimination, acceptable calibration, and stable temporal validation performance without requiring hospital-based electronic health record linkage. The HybridXGBRF had the highest AUROC among the evaluated models, but performance

XSL•FO
RenderX

differences from extreme gradient boosting were small. The model may serve as a risk-stratification tool to help identify residents who could benefit from structured care review, advance care planning, or palliative care assessment. Prospective implementation studies could determine its impact on care processes and resident- or family-centered outcomes.

long-term care facilities; mortality prediction; machine learning; AI; Taiwan

Introduction

The accelerating population aging at a global scale has established long-term care facilities (LTCFs) as cornerstones of geriatric health care systems [1,2]. For many older adults, LTCF transition is a major event in their health trajectory, often marked by precipitous functional decline and limited life expectancy [1,3]. This renders paramount accurate prognostic assessment at admission, not only to align clinical care with patient goals but also to facilitate timely advance care planning (ACP), optimize resource allocation, and ensure equitable access to palliative services [4,5]. Substantial early mortality has been reported after first-time LTCF admission, with approximately 1 in 5 residents dying within the first months of placement, and mortality rates markedly exceeding those in age-matched community populations [2,3]. Therefore, there is importance in promoting the early identification of LTCF residents at high risk for short-term mortality.

Several prognostic tools have been developed to estimate mortality risk among LTCF residents, mostly in the United States and predominantly using a minimum dataset (MDS) or related assessment instruments [5-10]. Examples include the Advanced Dementia Prognostic Tool, designed for residents with advanced dementia [7,9], and the MDS Mortality Risk Index for 6-month risk stratification [5,6,8]. Although several of these models have undergone prospective validation [6,7], most were developed more than a decade ago and may not reflect contemporary care practices, evolving resident acuity, or shifts in LTCF populations following postacute care policy changes. Recent initiatives have attempted to address these limitations, achieving mixed success. The Hospice Eligibility Prediction Index incorporates various clinical indicators of hospital admission history [11], while Jorissen et al [12] developed a comprehensive 51-variable model with individual-, medication-, system-, and health care–related factors known at entry into an LTCF. However, their clinical utility remains hindered by excessive complexity and a lack of external validation in a greater number of populations.

In such contexts, machine learning methods offer potential advantages for risk prediction, including the ability to model nonlinear associations and higher-order interactions within correlated clinical domains [13]. Recent reports have described improved discrimination when using machine learning models that incorporate demographic characteristics, comorbidities, and prior health care use [14,15]. Despite the potential, many of the extant machine learning models for mortality prediction remain dependent on acute care hospitalization data, which are often inaccessible or significantly delayed during the LTCF intake process. Furthermore, evidence of AI-driven prognosis in Asian LTCF contexts remains sparse, leaving a critical gap in health equity and geographical generalizability [16].

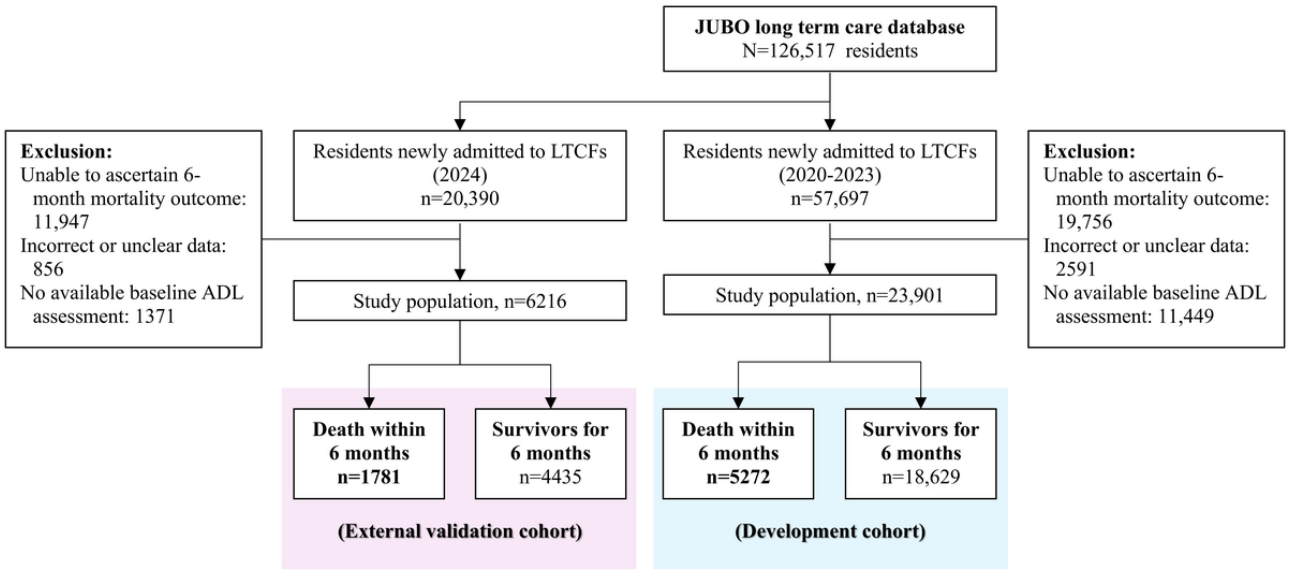
To address these gaps, this study aimed to, first, develop an interpretable machine learning prediction model to predict 6-month mortality among older adults newly admitted to LTCFs in Taiwan, using variables that are routinely collected at the time of admission or routine early-stay assessments. Second, to temporally externally validate the model using a later calendar-year cohort.

Methods

Study Design, Dataset, and Population

Taiwan's long-term care system provides a continuum of home-based, community-based, and institutional services for its rapidly aging population [17]. Residential LTCFs represent an institutional care setting within this continuum, serving older adults who require continuous assistance, supervision, nursing support, or help with activities of daily living (ADL) [18]. Accordingly, Taiwanese LTCF residents generally represent a frail and care-dependent population with substantial functional impairment, diverging from the broader community-dwelling older adult population. This study therefore focused on newly admitted LTCF residents, a clinically relevant point at which risk stratification may inform care planning, family communication, and ACP.

As aforementioned, we conducted a retrospective cohort study to develop and validate a machine learning model for predicting 6-month all-cause mortality among older adults newly admitted to LTCFs in Taiwan. This study used deidentified administrative and clinical assessment data routinely collected at the time of LTCF admission. Data were extracted from the JUBO Long-Term Care Database, a nationwide private administrative registry that captures structured admission, discharge, and clinical assessment data from LTCFs in Taiwan. The JUBO LTCFs system plays a significant role in Taiwan's long-term care market, with its services being used by 37.4% of all LTCFs nationwide (ie, a total of 636 institutions). Most (67.7%) of the facilities were in the south, 20% were in the central region, 11% were in the north, and a small number were in the east. This study was reported in accordance with the TRIPOD-AI (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis Or Diagnosis-Artificial Intelligence) statement (Checklist 1) [19].



The study sample comprised all residents with a first-time LTCF admission recorded in the JUBO database between January 1, 2020, and December 31, 2024. First-time admission was defined as the first LTCF admission recorded for a resident in the JUBO database during the study period. To enable temporal external

XSL•FO
RenderX

validation, we prespecified 2 nonoverlapping cohorts by admission date, as follows: a model development cohort including admissions from January 1, 2020, to December 31, 2023 (n=23,901); a temporal external validation cohort including admissions from January 1, 2024, to December 31, 2024 (n=6216).

To be included in this study, residents were not required to remain in the LTCF for the entire 6-month outcome window. Residents who died within 6 months after admission while under LTCF follow-up were classified as outcome events. Residents were excluded if their 6-month vital status could not be reliably ascertained, such as discharge or loss to follow-up before completion of the outcome window without subsequent status information in the JUBO database. The exclusion criteria also included implausible admission dates, duplicate records that could not be reconciled, and absence of any available baseline ADL assessment required to define baseline functional status. The cohort selection process, exclusions, and event counts are reported in Figure 1.

Figure 1. Flow diagram for study population inclusion. Unable to ascertain 6-month mortality outcome: residents discharged or lost to follow-up before completion of the 6-month outcome window whose postdischarge vital status was unavailable in the JUBO database. Residents who died within 6 months while under LTCF follow-up were included as outcome events. Incorrect or unclear data: records with implausible admission dates, inconsistent admission or discharge information, or duplicate records that could not be reconciled. No available baseline ADL assessment: residents with no recorded ADL assessment at admission and therefore no baseline ADL information available for feature construction. Residents with a baseline ADL assessment were retained in the analytic cohort even if individual ADL items were partially missing or if subsequent ADL information was insufficient to derive the ADL-change variable. These values were treated as predictor-level missingness and handled using the prespecified imputation procedure. ADL: activities of daily living; LTCF: long-term care facility.

Outcome, Predictors, and Data Preprocessing

Outcome Definition

The primary outcome was all-cause mortality within 6 months after LTCF admission. Mortality status and date of death were ascertained from the discharge or case-closure disposition fields in the JUBO database, which contains the recorded reason for case closure, including death, as documented by facility staff at the time of case closure. The outcome was operationalized as a binary indicator of death occurring within 6 months after LTCF admission. Postdischarge vital status data were not consistently available; thus, residents discharged or lost to follow-up before 6 months without subsequent status information were excluded from the primary analysis.

Candidate Predictors

Candidate predictors were prespecified through a 2-step process. First, we conducted a review of published prognostic models and studies on short-term mortality in LTCF and nursing home populations. Several repeatedly reported prognostic domains were identified, including demographics, functional status, comorbidity burden, recent acute care service use, nutritional risk, psychosocial status, and care-related factors (Multimedia Appendix 1). Second, we mapped these domains to the structured variables routinely collected in the JUBO LTCF assessment system, prioritizing predictors that were clinically interpretable, consistently available in routine LTCF workflows, and feasible to implement without linkage to hospital-based electronic health records. Although prior models have incorporated hospital-derived laboratory measures, such information is not consistently available during LTCF admission. Since this study prioritized real-world feasibility, we excluded laboratory variables from the analyses.

In addition to variables available at or shortly after admission, we also considered predictors capturing clinically meaningful changes during the early LTCF stay. This is because the intended use of the model is risk stratification using routinely collected data available at or before the time of risk estimation, not prediction based solely on variables fixed at the moment of admission. We accordingly included selected longitudinal or look-back variables that can be derived from routine LTCF records. Integrating these considerations, we prespecified candidate predictors, including age, sex, recent hospitalization history, level of consciousness measured by the Glasgow Coma Scale [20], ADL score [21], Geriatric Depression Scale-15 score [22], Study of Osteoporotic Fractures score [23], Mini

XSL•FO
RenderX

Nutritional Assessment—Short Form [24], Cumulative Illness Rating Scale for Geriatrics score [25], do-not-resuscitate documentation, number of medications, body weight, fall count, denture use, tube feeding, and use of respiratory aids. The selected longitudinal or look-back predictors, including hospitalization history, falls, weight change, and ADL change, were defined using prespecified assessment windows in the LTCF record. The operational definition, data source, and measurement window for each predictor, including whether it was available before admission, at admission, shortly after admission, or during routine follow-up before risk estimation, are detailed in Multimedia Appendix 2.

Predictor Measurement and Preprocessing

Predictors were extracted from structured fields recorded at admission and from routine LTCF assessments available before or at the time of risk estimation. Variables recorded after death, or otherwise unavailable at the corresponding risk-estimation time point, were not used.

ADL-related features were handled by distinguishing cohort eligibility from predictor-level missingness. Residents were required to have at least 1 baseline ADL assessment to define baseline functional status; those without such assessment were excluded. Among eligible residents, partially missing ADL items were treated as predictor-level missingness, not exclusion criteria. ADL change was calculated only when at least 2 ADL assessments were available within the prespecified assessment window before risk estimation. Otherwise, ADL change was treated as a missing predictor and handled using the prespecified imputation procedure.

Other variables representing recent clinical instability or longitudinal change, such as hospitalization count, falls, and weight change, were calculated using prespecified look-back or assessment windows before the corresponding risk-estimation time point. Continuous variables were retained on their original scales where appropriate, and categorical variables were encoded using standard binary or categorical representations. To balance data quality with feasibility and interpretability, candidate predictors with high missingness (>30%) were excluded from the model development cohort (Multimedia Appendix 3). The remaining missing values were handled using an imputation strategy.

Missing Data Handling

Guided by the clinical documentation patterns of the source database [26-28], we applied a pragmatic rule-based imputation strategy to handle missing values. For binary or count variables typically documented only when present in routine LTCF workflows (eg, do-not-resuscitate documentation, number of hospitalizations within the previous 6 months, falls, use of respiratory assistive devices, tube feeding, and denture use), missing entries were treated as indicating absence (coded as 0). This assumption reflects the usual documentation practice where the event is actively recorded when it occurs, although we acknowledge that under-documentation in some settings may lead to misclassification.

For continuous measures and scale scores, we standardized each variable using *z*-score normalization, with the mean and SD estimated from the model development cohort only. Then, we imputed missing standardized values as 0 (ie, the cohort mean on the original scale). This approach places missing values at a neutral reference point in the distribution, avoiding the imputation of implausible extremes [29]. All preprocessing parameters estimated in the development cohort were applied unchanged to the external validation cohort to prevent information leakage and mirror real-world deployment.

Model Development, Internal Evaluation, and Calibration

We compared 8 classification algorithms on their predictions of 6-month mortality (Multimedia Appendix 4) to investigate the prognostic advantage of advanced computational techniques over traditional statistical methods. The candidates were categorized into two groups, which are explored hereinafter.

1. Tree-based ensemble learners: This group included an extreme gradient boosting (XGB) classifier (gradient boosting) [30], a random forest classifier (bagging) [31], and our proposed hybrid of extreme gradient boosting and random forest [HybridXGBRF] approach. Ensemble models were selected because of their ability to capture intricate nonlinear feature interactions and robustness against noisy clinical data. The HybridXGBRF model is an ensemble architecture that integrates the predictive strengths of gradient boosting and bagging using a weighted probability blending (soft-voting) mechanism. For each prediction, the model computes a final probability P_{Hybrid}, which is as described below:

$$\text{PHybrid}=\alpha\cdot\text{PXGB}+(1-\alpha)\cdot\text{PRF},\ \alpha\in[0,1]$$

where P_{XGB} and P_{RF} are the predicted probabilities from the base learners, and α controls their relative contribution. The blending weight (α) was tuned via an exhaustive search over a prespecified range ($\alpha\in[0,1]$) in the development cohort. For each candidate α, the Hybrid probability was evaluated under the same cross-validation framework. The α yielding the best cross-validated performance (primary criterion: area under the receiver operating characteristic curve [AUROC]) was selected and then fixed for refitting on the full development cohort, as well as evaluation in the external validation cohort.

2. Linear statistical benchmarks: Five linear models were constructed as performance baselines, including standard logistic regression and regularized versions (ie, Ridge, L2 [32]; Lasso, L1 [33]; and Elastic Net [34]), to address potential multicollinearity among clinical predictors.

An internal model evaluation was conducted in the development cohort using 5-fold stratified cross-validation, preserving the event proportion in each fold. Within each fold, all preprocessing steps, including feature screening rules, imputation, standardization (when applicable), and model fitting, were performed using only the training partition and then applied to the corresponding validation partition. This fold-specific pipeline served to minimize information leakage. For each model and fold, we calculated the discrimination and classification performance metrics, as follows: AUROC, accuracy, precision, recall (sensitivity), F_1-score, and confusion matrix. Multimedia Appendix 5 presents the definitions of the evaluation metrics.

XSL•FO
RenderX

When the accuracy was summarized across folds, we reported the mean (SD), while probability accuracy was assessed using the Brier score whenever applicable. We prioritized the AUROC as the primary metric for model comparison because it is threshold-independent and less sensitive to class imbalance. Meanwhile, threshold-dependent metrics (precision, recall, or F_1) were reported at the classification threshold used across models for comparability.

Calibration was first evaluated using reliability diagrams. For each model, predicted 6-month mortality risks were grouped into deciles of predicted risk based on the predicted probability distributions. Within each bin, we calculated the mean predicted probability and observed event rate (ie, the proportion of residents who died within 6 months). These values were plotted against the 45-degree line representing perfect calibration. For internal evaluation and to reduce optimism, calibration curves were generated using out-of-fold predictions from the cross-validation procedure; for temporal external validation, calibration curves were generated using predictions from the final model applied to the 2024 cohort.

In addition to graphical and decile-based calibration assessments, we calculated calibration intercept, calibration slope, observed-to-expected ratio, and Brier score for the final HybridXGBRF model in both cohorts. Calibration intercept and slope were estimated using logistic recalibration; the observed-to-expected ratio was calculated as observed deaths divided by the sum of predicted probabilities; and the Brier score as the mean square difference between observed outcomes and predicted probabilities. CIs were estimated using resident-level bootstrap resampling. We also summarized calibration for the final HybridXGBRF model using risk-decile calibration tables, reporting the number of residents, observed deaths, observed risk, mean predicted risk, and predicted-risk range within each decile.

Temporal External Validation, Calibration, and Subgroup Analyses

To assess generalizability under a temporal dataset shift, we performed temporal external validation in the 2024 cohort (admissions in 2024), which was not used for model development, feature engineering decisions, or cross-validation. The final models were refitted to the full development cohort using the same predictors and preprocessing rules, and then evaluated in the external validation cohort.

All preprocessing parameters estimated in the development cohort (eg, scaling parameters for continuous variables) were applied to the external validation cohort. Model performance in the external validation was quantified using the same set of metrics as in the internal evaluation (Multimedia Appendix 5).

We additionally evaluated discrimination across sex, age (>85 and ≤85 years), and ADL decline (yes or no) to examine performance stability, reporting subgroup AUROC values using the same prediction pipeline.

Clinical Utility and Threshold Analyses

We conducted 2 complementary analyses for the HybridXGBRF model in the temporal external validation cohort in order to assess potential clinical utility beyond discrimination. First, we performed decision-curve analysis: net benefit was calculated across a range of threshold probabilities and compared with default strategies of classifying all residents as high risk or no residents as high risk. Second, we evaluated threshold-specific performance using clinically interpretable predicted-risk thresholds: for each threshold, we reported sensitivity (recall), specificity, positive predictive value, negative predictive value, F_1-score, and the proportion of residents classified as high risk. This analysis was intended to examine the trade-offs between case detection and alert burden under alternative risk-stratification thresholds.

Model Interpretability and Individual-level Risk Explanation

In an attempt to enhance clinical interpretability, we quantified feature contributions using Shapley Additive Explanations (SHAP) [35,36]. Because HybridXGBRF generates the final predicted probability as a weighted blend of the XGB and random forest component predictions, SHAP values were computed for the final HybridXGBRF blended prediction function. The reported feature attributions correspond to the final predicted probability of 6-month mortality, not to either component model alone. Global interpretability was visualized using SHAP beeswarm, and forest plots were used to rank feature importance across the study population. Local interpretability for individual-level risk explanations was demonstrated using SHAP force plots, illustrating how specific clinical features shifted the final HybridXGBRF-predicted probability from the baseline risk estimate.

Statistical Analysis

The descriptive characteristics of residents in the development cohort were summarized overall and by the 6-month mortality status. Group differences were quantified using standardized mean differences to describe the magnitude of imbalance between residents who died within 6 months and those who survived.

Intending to assess potential selection bias regarding cohort exclusion, we compared baseline characteristics between the development cohort and 2 major excluded groups: residents excluded because their 6-month mortality outcome could not be reliably ascertained and residents excluded because no baseline ADL assessment was available.

Model performance metrics were computed for internal evaluation and temporal external validation, as described earlier. For AUROC, precision, recall, F_1-score, accuracy, Brier score, and subgroup-specific performance metrics, 95% CIs were calculated using resident-level bootstrap resampling of the evaluation set.

For the purpose of comparing the discriminative performance of HybridXGBRF with XGB, we conducted paired bootstrap comparisons of AUROC within each cohort using 2000 resident-level bootstrap resamples. In each bootstrap sample, AUROC was calculated for both models using the same resampled residents, and the paired AUROC difference was computed as AUROC_HybridXGBRF−AUROC_XGB. The

XSL•FO
RenderX

95% CI was estimated from the empirical distribution of the paired AUROC differences, and 2-sided *P* values were calculated to test whether the paired difference differed from 0. Statistical significance was set at $P<.05$. Database management and extraction were conducted using PostgreSQL, and all statistical analyses were performed using Python (version 3.12.7; Python Software Foundation).

Sensitivity Analyses

The primary binary 6-month mortality evaluation was complemented by a time-to-event discrimination analysis using cumulative or dynamic area under the curve (AUC) at monthly time points before the 6-month end point. At each time point, cases were defined as residents who had died by that time, and controls were defined as residents who remained event-free beyond that time. Cumulative or dynamic AUC was calculated separately for the development and temporal external validation cohorts. This analysis evaluated whether model discrimination remained stable across earlier time horizons, while the primary model objective remained 6-month mortality risk prediction.

A concern arises here that missing binary or count variables may represent incomplete documentation, not true clinical absence. Thus, 2 additional post-hoc analyses were conducted to tackle this issue. For one, we examined whether missingness in selected key clinical assessments, including subsequent ADL reassessment, initial body weight, and Glasgow Coma Scale score, was associated with 6-month mortality by using missingness indicators for these variables as exposures in adjusted logistic regression models. For another, facility-level variation in overall documentation missingness was examined while stratified by facility size and geographic region, and heterogeneity across individual facilities was tested using a global chi-square test of independence. This analysis was conducted to assess whether missingness patterns reflected institutional documentation practices in addition to patient-level clinical status.

Ethical Considerations

This study was approved by the institutional review board of National Cheng Kung University Hospital (B-ER-112‐466). All data were anonymized prior to analysis, and the use of AI models was aligned with the ethical principles of transparency, clinical utility, and human oversight.

Results

Study Population and Characteristics

Between 2020 and 2023, 57,697 newly admitted LTCF residents were identified in the development cohort. After excluding residents whose 6-month mortality outcome could not be reliably identified (n=19,756), records with incorrect or unclear data (n=2591), and residents with no available baseline ADL assessment required for feature construction (n=11,449), the final development cohort included 23,901 residents from 493 LTCFs. Among them, 5272 residents died within 6 months after admission and 18,629 survived for at least 6 months. The participant flow diagram is presented in Figure 1.

Residents discharged or lost to follow-up before completion of the 6-month outcome window with unknown subsequent vital status were compared with the analytic cohort (Table S1 in Multimedia Appendix 6). Compared with the analytic cohort, this excluded group was younger and had higher ADL scores, higher body weight, lower prevalence of do-not-resuscitate documentation, and a higher prevalence of denture use. Facility size was similar between groups, although facility region differed; indicators of greater medical dependency, including tube feeding and respiratory support were not significantly different.

Residents excluded due to the absence of a baseline ADL assessment were similarly compared with the analytic cohort (Table S2 in Multimedia Appendix 6). This excluded group (vs analytic cohort) was slightly younger and had lower Modified Cumulative Illness Rating Scale for Geriatric Patients scores, lower prevalence of do-not-resuscitate documentation, fewer hospital admissions within 6 months, and markedly lower documentation of denture use, tube feeding, respiratory support, and fall history.

The characteristics of the development cohort are summarized in Table 1. The mean age was 79.3 (SD 11.8) years, and 12,155 (50.9%) residents were female. Residents who died within 6 months (vs who survived for at least 6 months) had greater functional impairment, lower body weight, more frequent hospital admissions, and higher use of tube feeding and respiratory support. Standardized mean differences greater than 0.1 were observed for Cumulative Illness Rating Scale for Geriatrics, ADL measures, body weight, number of hospitalizations, sex, do-not-resuscitate documentation, denture use, tube feeding, respiratory support, and institutional region.

In 2024, a total of 20,390 newly admitted LTCF residents were identified for temporal external validation. After applying the predefined exclusion criteria, the temporal external validation cohort included 6216 residents from 548 LTCFs. Among them, 1781 residents died within 6 months after admission, and 4435 survived for at least 6 months. The mean age was 78.6 (SD 11.7) years, and 3043 (49%) residents were female. Baseline

Model Development, Internal Evaluation, and Calibration

The performance of the 8 classification algorithms in the internal evaluation is summarized in Table 3 and Figure 2. Overall, the linear models were outperformed by the tree-based models (eg, HybridXGBRF, XGB, and random forest), achieving higher AUROC values (0.87 - 0.89 vs 0.86), higher sensitivity or recall (0.51 - 0.54 vs 0.48 - 0.49), and higher F_1-scores (0.62 - 0.64 vs 0.57 - 0.58).

XSL•FO
RenderX

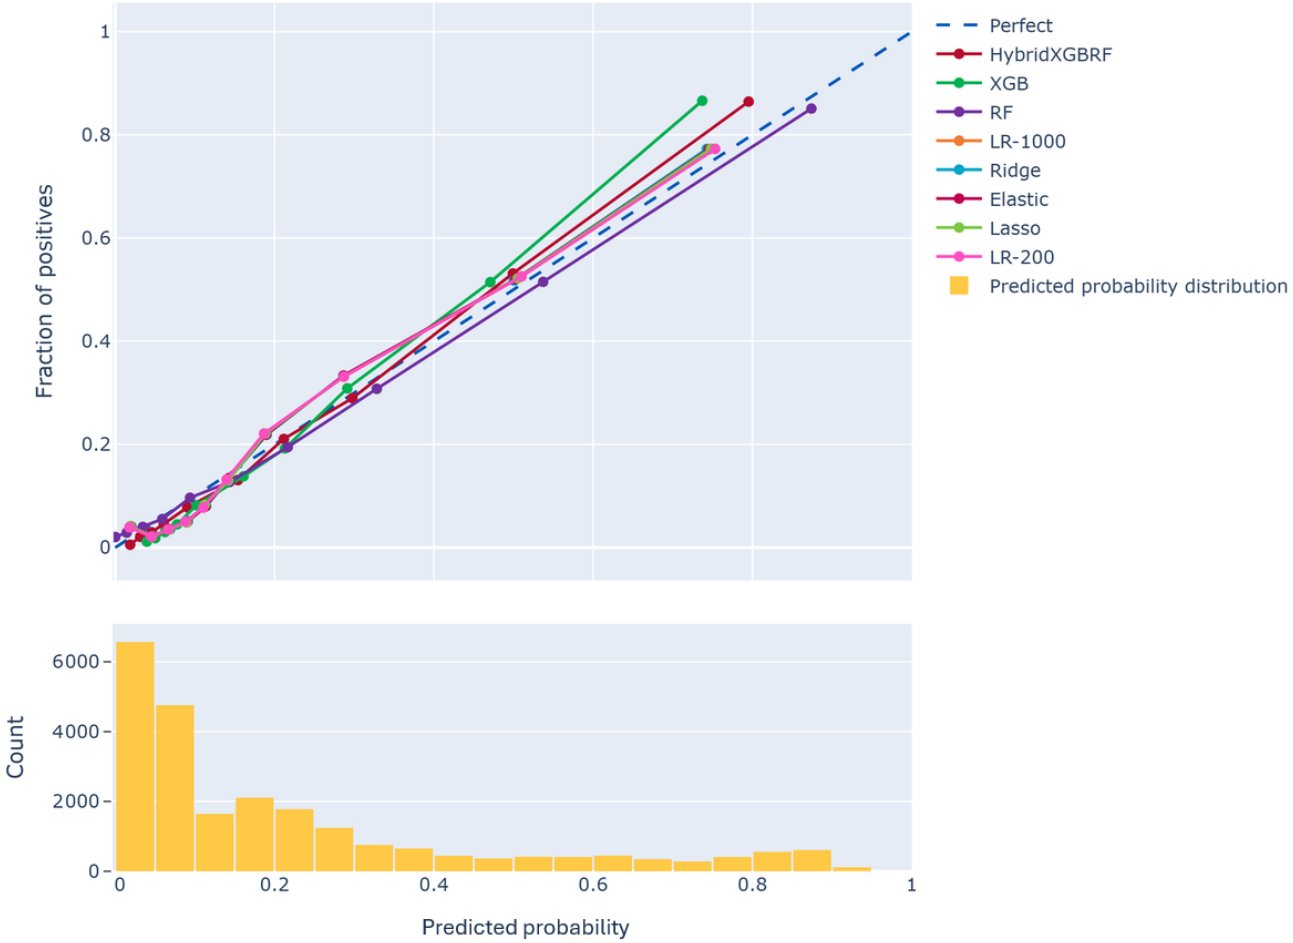
Among all evaluated algorithms, the HybridXGBRF model achieved the best overall internal performance, with the highest AUROC (0.89, 95% CI 0.88 - 0.89), highest F_1-score (0.64, 95% CI 0.63 - 0.65), highest accuracy (0.87, 95% CI 0.86 - 0.87), and lowest Brier score (0.10, 95% CI 0.10 - 0.10). The linear models contrasted this, showing lower classification performance, particularly for sensitivity and F_1-score.

Figure 3 presents the confusion matrices of the evaluated models. Specificity remained consistently high across models (range 0.94 - 0.96), and sensitivity was more modest (range 0.48 - 0.54). Compared with XGB, the HybridXGBRF model identified more positive cases (2824 vs 2685) and achieved higher sensitivity and F_1-score, although XGB generated fewer false-positive predictions (710 vs 761). These findings are aligned with the AUROC, F_1-score, and Brier score results reported in Table 3.

XSL•FO
RenderX

Figure 3. Confusion matrix comparisons between machine learning classifiers. HybridXGBRF: hybrid of extreme gradient boosting and random forest; XGB: extreme gradient boosting.



The HybridXGBRF model also demonstrated strong internal calibration. The observed-to-expected (O/E) ratio was 1.00 (Multimedia Appendix 7). Predicted probabilities closely followed the reference 45-degree line across the low-to-moderate

XSL•FO
RenderX

predicted-risk range (Figure 4) based on the risk-decile distribution (Table S1 in Multimedia Appendix 8). A small degree of underestimation was observed in the highest predicted-risk bin (>0.7), while quantitative calibration metrics showed a calibration slope of 1.21 and an intercept of 0.20. Overall, the HybridXGBRF model achieved the lowest internal Brier score (0.10) among the evaluated models (Multimedia Appendix 9), and tree-based models generally showed lower Brier scores than linear models (Table 3). In paired bootstrap comparisons, HybridXGBRF demonstrated a statistically significant but small AUROC improvement over XGB (Multimedia Appendix 10). In the development cohort, the AUROC difference was 0.003 (95% CI 0.002 - 0.005; P<.001).

Figure 4. Calibration plots and distributions of the machine learning models in the development cohort. HybridXGBRF: hybrid of extreme gradient boosting and random forest; LR: logistic regression; RF: random forest; XGB: extreme gradient boosting.

Temporal External Validation, Calibration, and Subgroup Analyses

In the temporal external validation cohort, the models' predictive performance remained stable, indicating good temporal generalizability. The HybridXGBRF model achieved an AUROC of 0.90 (95% CI 0.89 - 0.91), comparable to its internal evaluation performance, as well as achieved an F_1-score of 0.68 (95% CI 0.66 - 0.70), accuracy of 0.85 (95% CI 0.84 - 0.86), and Brier score of 0.11 (95% CI 0.11 - 0.12; Table 4).

[j]AUROC: area under the receiver operating characteristic curve.

Tree-based models again outperformed linear models in temporal external validation. Tree-based models (vs linear models) showed higher AUROC values (0.88 - 0.90 vs 0.87), higher F_1-scores (0.67 - 0.68 vs 0.63), and higher accuracies (0.84 - 0.85 vs 0.82). In the paired bootstrap comparison, HybridXGBRF showed a small but statistically significant AUROC improvement over XGB in the temporal external validation cohort, with an AUROC difference of 0.004 (95% CI 0.001 - 0.006; *P*=.003; Multimedia Appendix 10).

External validation showed that HybridXGBRF maintained the strongest calibration among the evaluated models, with the lowest Brier score (0.11; Figure 5 and Table 4). Regarding quantitative calibration metrics, the O/E ratio was 1.13, calibration slope of 1.27, and intercept of 0.52 (Multimedia Appendix 7). The detailed risk-decile analysis (Table S2 in Multimedia Appendix 8) showed that the calibration curve closely followed the reference line across most probability ranges, with mild divergence at higher predicted risks. Tree-based models demonstrated better calibration robustness than linear models (Multimedia Appendix 9).

XSL•FO
RenderX

Figure 5. Calibration plots and distributions of the machine learning models in the external validation cohort. HybridXGBRF: hybrid of extreme gradient boosting and random forest; LR: logistic regression; RF: random forest; XGB: extreme gradient boosting.

Subgroup analyses demonstrated that the HybridXGBRF model maintained high and consistent discrimination across sex and age strata, with AUROC values ranging from 0.89 to 0.90 (Table 5). It also showed high discrimination among residents with ADL improvement, with an AUROC of 0.91 (95% CI 0.90 - 0.92), F_1-score of 0.71 (95% CI 0.69 - 0.73), and accuracy of 0.85 (95% CI 0.84 - 0.86). Performance was lower among residents with ADL decline, with an AUROC of 0.71 (95% CI 0.66 - 0.75) and sensitivity of 0.03 (95% CI 0.01 - 0.07).

Clinical Utility and Threshold Analyses

Decision-curve analysis showed that the HybridXGBRF model provided higher net benefit than the default strategies. These default strategies involved classifying all residents as high risk or no residents as high risk across a clinically relevant range of threshold probabilities in the temporal external validation cohort (Multimedia Appendix 11).

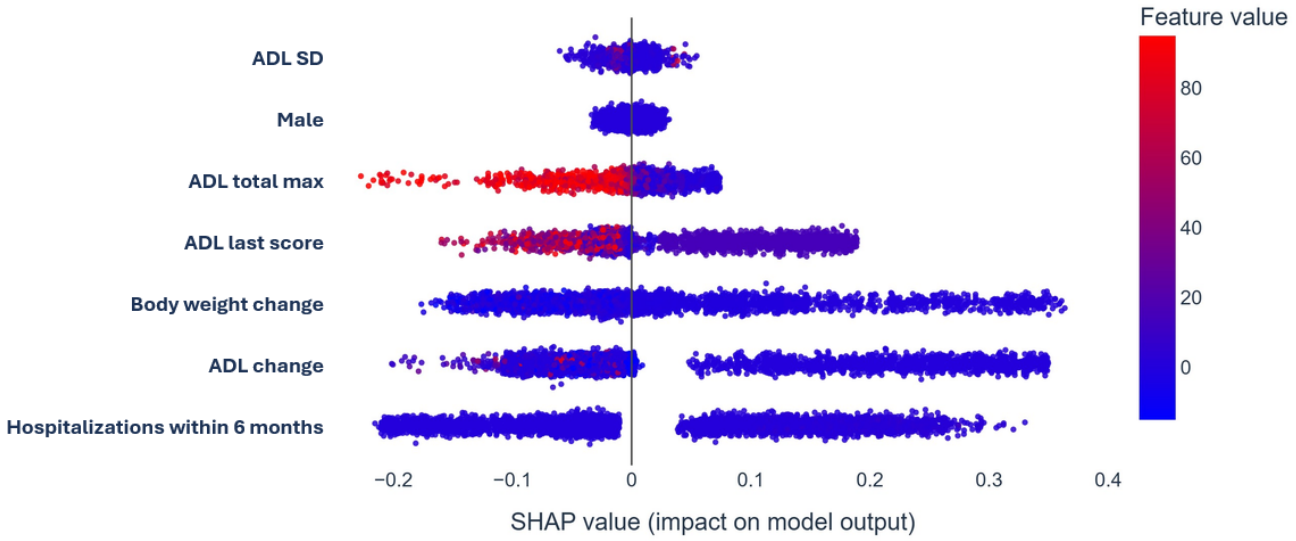
Alternative threshold analyses demonstrated the expected trade-off between case detection and alert burden (Multimedia Appendix 12). At a predicted-risk threshold of 0.20, the model achieved high sensitivity (0.86) and negative predictive value (0.93), but classified 2659 residents as high risk, corresponding to 42.8% of the temporal external validation cohort. At a threshold of 0.30, the model provided a more balanced profile, with sensitivity of 0.72, specificity of 0.88, positive predictive value of 0.71, and the highest F_1-score among the evaluated thresholds (0.72). At a threshold of 0.50, specificity and positive predictive value increased to 0.961 and 0.86, respectively, but sensitivity decreased to 0.57. The combination of the findings here outlines that lower thresholds prioritized sensitivity at the cost of more high-risk classifications, whereas higher thresholds prioritized specificity and positive predictive value at the cost of reduced sensitivity.

Model Interpretability and Individual-Level Risk Explanation

Figure 6 (ie, showing the distribution of individual SHAP values in a beeswarm plot) and Figure 7 (ie, showing the mean absolute SHAP values with 95% CIs in a forest plot) present SHAP-based explanations for the final HybridXGBRF blended prediction output. Across both visualizations, recent hospitalizations within the past 6 months made the largest overall contribution to the final HybridXGBRF-predicted 6-month mortality risk, with higher hospitalization counts generally contributing positively to predicted risk.

XSL•FO
RenderX

Figure 6. SHAP beeswarm plot of the HybridXGBRF model. ADL: activities of daily living; HybridXGBRF: hybrid of extreme gradient boosting and random forest; SHAP: Shapley Additive Explanations.



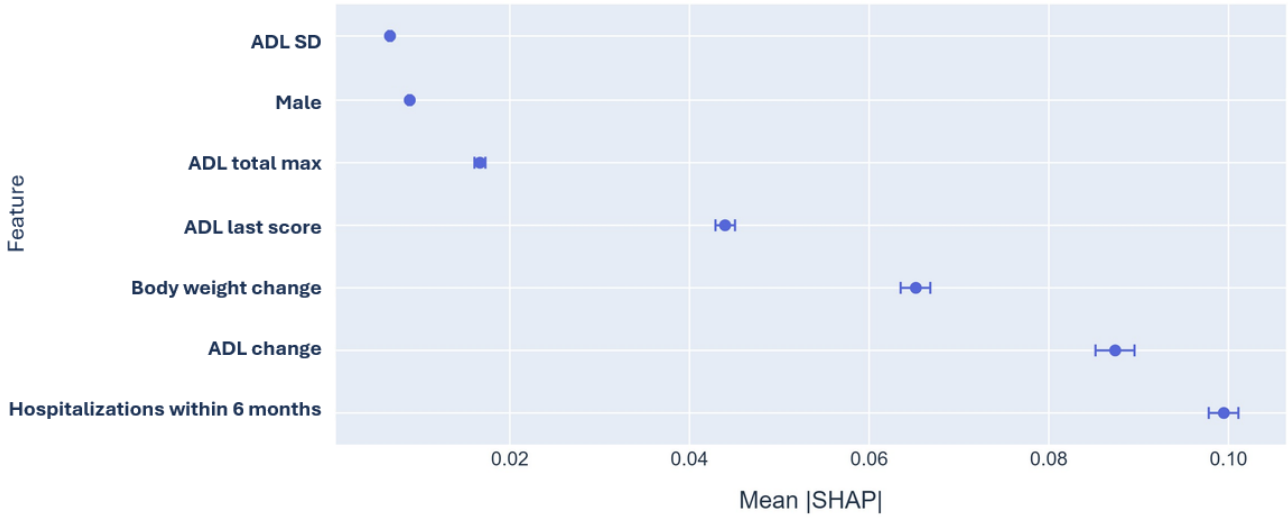


Figure 7. SHAP forest plot of the HybridXGBRF model. ADL: activities of daily living; HybridXGBRF: hybrid of extreme gradient boosting and random forest; SHAP: Shapley Additive Explanations.

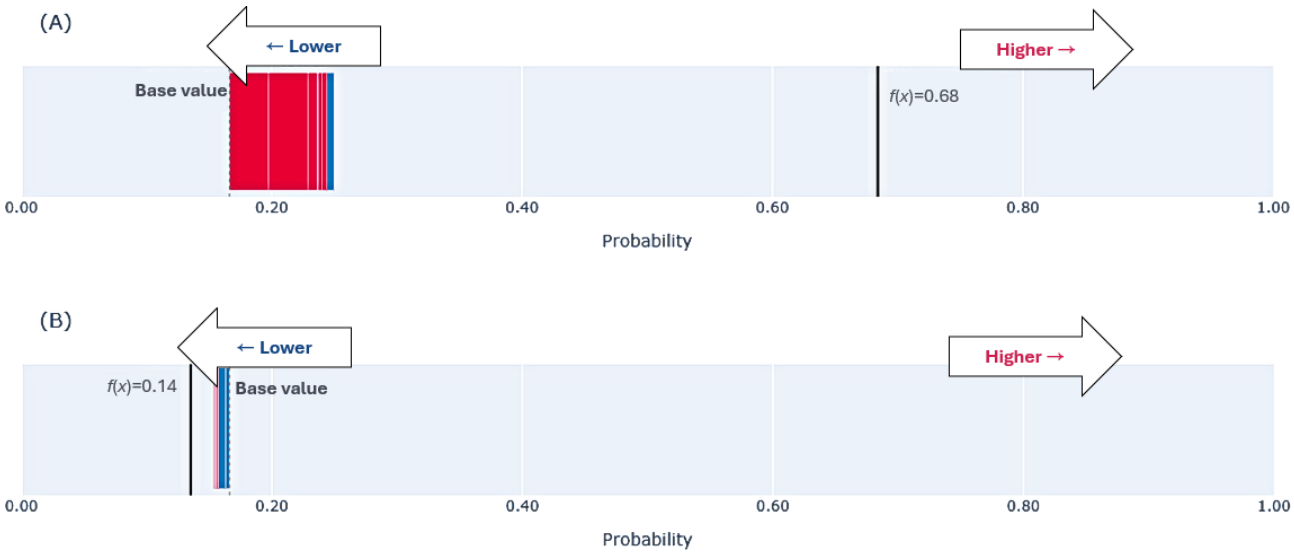

Functional status was also a key determinant of predicted mortality risk. More recent and lower ADL scores, ADL decline, and variability across ADL measurements were associated with increased predicted risk, as reflected by the predominantly positive SHAP values. Conversely, higher maximum ADL scores contributed modestly to lower predicted mortality risk.

Nutritional indicators were similarly influential. Sequential declines in body weight shifted SHAP values upward, indicating heightened predicted risk following nutritional deterioration. Male residents generally showed slightly higher predicted mortality risk than female residents, hence showing that sex contributed to the prediction.

Figure 8 illustrates the SHAP force plots for 2 representative residents. For the positively predicted case (Figure 8A), multiple high-risk features collectively shifted the prediction from the baseline mortality probability (~0.21) to a substantially higher estimated risk (0.68). The contributing factors (ie, pushed the prediction to a higher risk) included impaired functional status, recent functional decline, lower or decreasing body weight, male sex, and recent hospitalization. For the negatively predicted case (Figure 8B), a minimal deviation from the baseline probability (~0.14) was observed, with predominantly protective features (eg, preserved functional ability, stable body weight, and the absence of recent acute care service use) driving the SHAP values toward a lower predicted risk. These examples highlight the manner in which the HybridXGBRF model integrates functional, nutritional, and clinical history features to generate patient-specific risk estimates.

Sensitivity Analyses

In both cohorts, cumulative or dynamic AUCs remained above 0.89 across months 1 to 5, indicating stable discrimination across the earlier time horizons (Multimedia Appendix 13). In the sensitivity analysis evaluating missingness mechanisms, missingness in subsequent ADL assessment, initial body weight, and Glasgow Coma Scale score was significantly associated with 6-month mortality in both cohorts (adjusted odds ratio ranges 13.7 - 16.6, 3.0 - 3.1, and 1.2 - 1.3, respectively; all $P \leq .01$; Multimedia Appendix 14). Overall documentation missingness varied significantly across the 493 individual facilities (χ^2_{492}=140,786.0; P<.001; Cramer V=0.451), with minimal variation by facility size (7.7% - 8.0%) and greater variation by region (5.5% - 12.1%; Multimedia Appendix 15)[37].

Discussion

Principal Findings

This study developed and temporally externally validated an explainable machine learning model for predicting 6-month all-cause mortality among newly admitted LTCF residents using routinely collected LTCF assessment data. In the temporal external validation cohort, the HybridXGBRF model achieved strong discrimination (ie, AUROC of 0.90) without requiring integration with hospital electronic health records nor data collection beyond standard LTCF assessments. Although HybridXGBRF achieved the highest AUROC among the evaluated models, the absolute improvement over XGB was modest. SHAP analysis pinpointed the most influential predictors as frequent hospitalizations within 6 months, ADL impairment, and weight loss, providing clinically interpretable risk attributions at the individual level. The model also maintained stable discrimination across the sex and age subgroups. Therefore, a parsimonious set of routinely collected LTCF variables, when analyzed through an interpretable machine learning framework, may support risk stratification and structured care planning in Taiwanese long-term care settings.

Interpretation in Context of the Existing Literature

The performance of our model compares favorably with that of established prognostic tools for LTCF populations. The MDS Mortality Risk Index is a validated prognostic tool designed to estimate the risk of 6-month mortality in nursing home residents, and it uses routinely collected clinical and demographic data from the MDS assessment [5,6,8]. The original MDS Mortality Risk Index and its revised versions (MDS Mortality Risk Index-Revised and MDS Mortality Risk Index [version 3]) have demonstrated good discrimination for predicting 6-month mortality (AUROC 0.75 - 0.81) and have been adapted for use in various settings, including nursing homes and community-based care [5,6,8]. Moreover, the Advanced Dementia Prognostic Tool score, specifically designed for residents with advanced dementia, reported an AUROC of 0.67 (95% CI 0.62 - 0.72) [7,9]. More recent approaches include the Hospice Eligibility Prediction Index using hospital diagnoses and age (AUROC 0.838) [11] and Jorissen's comprehensive model using 51 variables (AUROC 0.82), such as individual-level factors, LTCF-level factors, medication history, and health (hospital and medical practitioner) service use [12]. In the 2022 study by Chandra et al [14], an AUROC of 0.84 was reported for predicting mortality among hospitalized patients discharged to LTCFs, albeit this model also required extensive hospitalization data (eg, laboratory results and imaging findings). Importantly, models that depend on detailed hospital-derived diagnoses, medication histories, or longitudinal health service use may not consistently have at their disposal the data (or these data may not be readily linkable) they require to provide their predictions, potentially constraining their scalability and routine implementation in many care settings.

Standing apart from several preceding models, our model achieved strong discrimination using a smaller set of predictors, all of which are routinely documented in standard LTCF admission or early-stay assessments. This parsimony is a deliberate design choice that prioritizes real-world actionability:

XSL•FO
RenderX

by avoiding reliance on hospital-derived diagnoses, medication histories, or granular use data, the model can be executed at, or shortly after, LTCF entry, a point at which timely prognostic awareness may highly meaningfully support ACP and goal-concordant care. This positioning is conceptually aligned with the established Changes in Health, End-Stage Disease, and Signs and Symptoms scale, which uses MDS- or International Resident Assessment Instrument–derived clinical indicators to predict short-term mortality and offers substantial improvement in prognostic precision [38]. Still, while the Changes in Health, End-Stage Disease, and Signs and Symptoms 3.0 [39] scale exhibits moderate discrimination for short-term death (AUROC of 0.72 - 0.76 for 30- to 60-day periods), our model achieved a strong AUROC of 0.90 for 6-month mortality in the external validation. What this entails is that by leveraging machine learning to analyze functional trajectories and acute care history (ie, rather than relying primarily on symptomatic clusters), we can provide a resilient and accurate predictive signal supportive of longitudinal care coordination and resource allocation.

Our model was developed and temporally validated in Taiwanese LTCF residents, a population embedded within a long-term care system that includes home-based, community-based, and residential services. Moreover, the baseline characteristics and event rates of our cohort reflect a high-risk institutional population, characterized by substantial functional dependency and 6-month mortality rates of 22.1% in the development cohort and 28.7% in the temporal validation cohort. These mortality rates are broadly consistent with those reported in high-acuity nursing home and long-term care populations internationally [1,2]. Notwithstanding, direct comparisons should be interpreted cautiously, given cross-national differences in admission thresholds, assessment instruments, financing mechanisms, and availability of home- and community-based alternatives.

Most existing mortality prediction tools for LTCF or nursing home residents have been derived from Western cohorts, particularly US MDS-based populations [5-8,11,14]. However, differences in disease prevalence, health care use patterns, long-term care policy, family caregiving availability, cultural attitudes toward end-of-life care, and population health characteristics may limit the generalizability of Western-derived models to Asian LTCF settings [16]. By developing and temporally validating a prediction model using Taiwanese long-term care data, this study contributes region-specific evidence. It outlines that interpretable machine learning can achieve strong discrimination using locally relevant, routinely collected variables. It remains that the greater applicability of the model extends to LTCFs serving functionally dependent and medically complex older adults. External validation and, if necessary, local recalibration would be needed before applying the model to lower-acuity residential care, assisted living settings, or health systems with substantially different care delivery models.

Reliance on machine learning models (vs traditional logistic regression) reflects a deliberate trade-off between interpretability and predictive power. Although logistic regression offers a straightforward coefficient interpretation, it assumes linear relationships and cannot capture complex interactions among predictors without an explicit specification [40]. To address the interpretability challenge inherent in ensemble methods, we used SHAP analysis, which decomposes individual predictions into additive feature contributions grounded in cooperative game theory [35,36]. SHAP analysis revealed that frequent hospitalizations within 6 months, ADL impairment, and weight loss were the most influential predictors; these findings strongly align with established geriatric prognostic frameworks [3,41]. Functional decline (as measured by ADL scores) is a consistent and robust mortality predictor across diverse care settings [3,41]. Weight loss, particularly unintentional loss exceeding 5% of body weight, serves as a clinical marker of frailty, malnutrition, and underlying systemic illnesses [42]. The concordance between the SHAP-identified features and clinically validated risk factors enhances the model's credibility, which may facilitate acceptance among care teams that may otherwise be skeptical of algorithm-driven recommendations.

Additionally, our model was developed and validated exclusively in Taiwanese LTCF residents, specifically and purposefully representing an Asian population. Meanwhile, most existing mortality prediction tools have been derived from Western cohorts, primarily using US MDS registries [5-8,11,14]. The ethnic and geographic differences in disease prevalence, health care use patterns, cultural attitudes toward end-of-life care, and nutritional status may limit the generalizability of Western-derived models to Asian contexts [16]. By developing a prediction model grounded in Taiwanese long-term care data, this study contributes region-specific evidence, emphasizing that interpretable machine learning approaches can achieve strong performance using locally relevant variables.

Subgroup Performance and Algorithmic Fairness

A particularly noteworthy finding was the exceptional performance of the model (accuracy=0.85) among residents who demonstrated ADL improvement after LTCF admission. Functional improvement is typically clinically interpreted as a positive prognostic indicator, being used as a quality metric in institutional care [43,44]. However, a meaningful subset of residents with improving functional status may still face an elevated short-term mortality risk according to our findings, a pattern that may be difficult to identify using conventional clinical assessments alone.

Several mechanisms can explain this paradoxical association. First, some residents may experience transient functional recovery or "terminal lucidity," referring to brief improvements in cognitive or physical function shortly before death, a phenomenon documented in the palliative care literature [45,46]. Second, residents with very low baseline ADL may show relative improvement from institutional rehabilitation while still harboring severe underlying comorbidities or physiological frailty, which may not be fully captured by functional measures alone [47,48]. Similarly, selection effects may operate such that residents admitted to LTCFs in acute decompensation states show functional "improvement" simply by returning toward their prior baseline, yet remain at a high mortality risk due to the severity of the precipitating illness or frailty [47,49].

From an algorithmic fairness perspective, this subgroup represents cases where human clinical judgment is most likely

XSL•FO
RenderX

to underestimate risk, referring to situations sometimes termed "false reassurance" scenarios. The ability of the model to identify elevated mortality risk even in the presence of functional improvement has significant implications for ACP. This holds potential to enable timely goals-of-care conversations and referrals to palliative services for residents whose improving ADL trajectories could otherwise delay such discussions. The potential complementary role of algorithmic decision support is also emphasized here, showing that it does not replace clinical expertise but brings to the surface risk patterns that may be counterintuitive or masked by seemingly positive clinical indicators.

Subgroup analyses demonstrated the model's stable performance across sex and age strata with minimal variation in discrimination (AUROC range 0.89 - 0.90). Therefore, the model does not seem to systematically disadvantage specific demographic groups. This is key if we consider the ongoing concerns regarding algorithmic bias in health care AI [50]. Overall, the evidence from subgroups underlines the model's robustness across key demographic strata, as well as the necessity of a prospective evaluation of whether risk signals in seemingly improving residents translate into better-timed, goal-concordant care when embedded in routine LTCF workflows.

Potential Clinical and Operational Applications

Short-term mortality prediction in LTCFs may support several clinical and operational purposes, including ACP, palliative care assessment, medication review, family meetings, and resource planning [4]. Prognostic information can facilitate serious illness communication and goals-of-care discussions when embedded within structured clinical workflows, although evidence specific to LTCF settings remains lacking [13,51]. In addition, prior work in nursing home residents with advanced dementia has shown that prognostic tools may inform hospice eligibility discussions and care planning, while also underscoring the limitations of relying on prognostic models alone [7]. We put forward that the present model should be interpreted as a risk-stratification tool with potential clinical utility, rather than as evidence that model-guided care will necessarily improve outcomes [19].

Our model has several features that may support future implementation. First, it relies on variables available through LTCF assessment workflows, enabling risk stratification shortly after LTCF entry without requiring hospital record linkage or specialized testing. Second, it generates calibrated probability estimates, not categorical risk labels, allowing facilities to define thresholds according to local resources, resident and family preferences, and palliative care capacity. The threshold and decision-curve analyses also indicate that no single cutoff is optimal for all clinical purposes: lower thresholds may reduce missed high-risk residents but increase the number of residents flagged for review, whereas higher thresholds may reduce alert burden but miss more residents who die within 6 months. Thus, threshold selection should be linked to the intended clinical action and the relative consequences of false-negative versus false-positive classifications [52].

Third, SHAP-based explanations provide interpretable feature contributions that may help clinicians contextualize risk estimates using clinically meaningful domains, such as functional dependency, recent acute-care use, and nutritional decline. Some model features, such as weight loss and frequent hospitalization, should be interpreted as clinically recognizable signals that prompt further assessment, not that provide direction for treatment targets. For example, these signals may lead interdisciplinary teams to review nutritional status, symptom burden, recent care transitions, medication burden, or potentially reversible contributors to functional decline [53,54].

However, clinical utility cannot be assumed from discrimination and calibration alone. These metrics indicate that the model can rank residents by risk and estimate probabilities, while failing to demonstrate that using the model changes clinician behavior, improves care quality, or enhances resident- and family-centered outcomes [17,52]. This brings forth the need for future prospective impact and implementation studies before routine deployment [55]. Such studies should prespecify intended use, risk thresholds, and linked clinical actions; assess workflow integration and implementation outcomes such as acceptability, adoption, appropriateness, feasibility, fidelity, and sustainability; evaluate potential benefits and harms, including ACP uptake, palliative care referral, hospitalization, quality of end-of-life care, family experience, equity, and unintended consequences.

Limitations

This study had several limitations. First, as this was a retrospective analysis of the JUBO database, the findings may be affected by documentation heterogeneity, documentation bias, and unmeasured facility-level effects. Differences in staffing patterns, care protocols, and documentation practices may influence both predictor recording and mortality risk. Facility-level clustering was also not explicitly modeled, and for selected binary or event-based variables, missing values were coded as absence according to the structure of routine LTCF documentation. This later-mentioned approach may conflate true clinical absence with incomplete recording. In sensitivity analyses, missingness in key clinical assessments was significantly associated with 6-month mortality, and facility-level documentation completeness showed significant heterogeneity across facilities and regions (Multimedia Appendices 14 and 15), raising the possibility of informative missingness, not just random documentation gaps. We thus need standardized assessment workflows, routine monitoring of facility-level missingness, and future evaluation of alternative missing-data strategies before prospective implementation of the model.

Second, data availability and temporal measurement limitations may have affected model granularity, benchmark selection, and predictor timing. Although we prioritized routinely available LTCF data to enhance real-world applicability, several potentially high-impact predictors, such as variables related to frailty or specific comorbidities, were excluded because missingness exceeded 30%, which may have reduced the model's clinical granularity. In addition, direct comparison with established MDS- or International Resident Assessment Instrument–based clinical risk scores was not feasible because

XSL•FO
RenderX

the required scoring components are not routinely used in Taiwanese LTCF workflows and were not fully available in the JUBO database. Some predictors also reflected information obtained during routine LTCF assessments after admission rather than strictly at the moment of admission. Although these variables were selected to reflect real-world longitudinal risk monitoring, their use may introduce temporal ambiguity or possible information leakage if the timing of risk estimation is not clearly aligned with predictor availability. Prospective implementation should ensure that each predictor is available before the risk estimate is generated.

Third, post-LTCF discharge vital status data were not consistently available in the JUBO database. Residents discharged or lost to follow-up before completion of the 6-month outcome window without subsequent status information were excluded from the primary analysis. Although the baseline characteristics of included and excluded residents were compared to assess potential selection bias, residual bias cannot be fully excluded because postdischarge mortality could not be directly observed.

Fourth, this study primarily modeled death within 6 months as a binary outcome. Despite adding cumulative or dynamic AUC analyses to evaluate discrimination across earlier time horizons, this approach provides only a complementary time-to-event discrimination assessment, hence not replacing formal survival modeling or fully accounting for censoring and time-to-death. Future studies should compare Cox regression, random survival forests, or gradient-boosted survival models with binary classification approaches to support dynamic risk prediction and updating during LTCF stay.

Fifth, the model's transportability may be affected by cross-national differences in long-term care systems and temporal changes in baseline risk. LTCF admission thresholds vary across countries and may be shaped by financing mechanisms, family caregiving availability, home- and community-based service capacity, and national long-term care policies. In temporal external validation, quantitative calibration analyses showed modest underestimation of observed mortality, particularly at higher predicted-risk levels. This shows that calibration may shift over time or across care settings. External validation, calibration monitoring, and, if necessary, local or temporal recalibration are required before implementation in substantially different care settings.

Finally, the study period encompassed the COVID-19 pandemic, which may have affected LTCF mortality, admission case mix, hospitalization patterns, staffing, infection-control practices, and care delivery. Interpretations of the observed 6-month mortality rates of 22.1% in the development cohort and 28.7% in the temporal validation cohort should thus account for the aforementioned factors. Nevertheless, the model maintained comparable discriminative performance across the development and 2024 temporal validation cohorts, suggesting that the main person-level predictors retained prognostic value despite temporal changes in baseline risk. Validation in future postpandemic cohorts remains warranted.

Future Directions

Future methodological work should go beyond periodic model updating and monitoring of calibration drift, also examining dynamic longitudinal prediction approaches. More recent temporal event prediction methods, including continuous estimation of temporal pattern completion for event prediction, may provide useful frameworks for incorporating repeated ADL assessments, weight trajectories, hospitalization events, falls, resident-reported outcomes, symptom burden, and evolving care needs into updated mortality risk estimates during LTCF stay.

Conclusions

This study developed and temporally externally validated an interpretable machine learning model for predicting 6-month mortality among older LTCF residents in Taiwan using routinely collected LTCF assessment data. The model achieved strong discrimination and acceptable calibration without requiring hospital-based electronic health record linkage, suggesting potential feasibility for risk stratification within LTCF assessment workflows—albeit future prospective impact and implementation studies are recommended before actual deployment in real-world settings. Key predictors, including recent hospitalization, functional dependency and instability, and nutritional decline, were clinically coherent and aligned with geriatric prognostic domains. Prospective implementation studies, formal survival modeling, and external validation in other long-term care systems are needed to determine clinical impact, support dynamic risk updating, and assess broader transportability.

Acknowledgments

The authors thank Smart Ageing Tech Co, Ltd, for their technical support and Ms Chun-Han Tsai for her assistance in this project. The authors also show their appreciation to Professor Sheng-Hsiang Lin and the Biostatistics Consulting Center of National Cheng Kung University Hospital for providing statistical consultation and methodological advice. A portion of the grant funding (NSTC 114-2321-B-006-013) was used to commission the assistance services of Smart Ageing Tech Co, Ltd, for model programming and data processing tasks. The intellectual property of the developed models remains with the research team and the funding agency.

Abstract

Background: Mobility limitations in older adults are associated with an increased physiological cost of walking, reduced functional independence, and elevated fall risk. Conventional wheeled walkers improve stability but lack real-time physiological monitoring and safety feedback. Digital health–enabled assistive devices integrating physiological monitoring and fall detection may enhance mobility performance and safety.

Objective: This study aimed to evaluate the short-term effects of a smart wheeled walker equipped with real-time physiological monitoring and fall detection compared with a standard wheeled walker in improving walking efficiency, dynamic balance, and fear of falling among community-dwelling older adults.

Methods: A single-blind randomized crossover trial was conducted in 30 community-dwelling older adults aged 65 to 80 years with mild balance impairment (Timed Up and Go >13.5 seconds). Participants completed walking trials using both a standard wheeled walker and a smart wheeled walker in a randomized order, with a 30-minute washout period. The smart walker integrated photoplethysmography-based heart rate (HR) monitoring, pulse oximetry (oxygen saturation [SpO_2]), and a tilt-based fall detection system with mobile alert functionality. The primary outcome was walking efficiency assessed using the Physiological Cost Index (PCI). Secondary outcomes included dynamic balance (Expanded Timed Up and Go [ETUG]) and fear of falling (Falls Efficacy Scale-International). Statistical analysis was performed using paired comparisons with a significance level of $P<.05$.

Results: Thirty (100%) participants completed both intervention conditions and were included in the final analysis. Walking speed was significantly higher with the smart wheeled walker than the standard wheeled walker (mean 28.77, SD 11.94 vs mean 18.14, SD 14.55 m/min; mean difference −10.63 m/min, 95% CI −17.51 to −3.75 m/min; $P<.001$). The PCI was significantly lower with the smart wheeled walker (mean 0.36, SD 0.38 vs mean 0.69, SD 1.23 beats/m; mean difference 0.33 beats/m, 95% CI 0.06 - 0.60 beats/m; $P=.02$), indicating improved walking efficiency. Participants also completed the ETUG test significantly faster with the smart wheeled walker (mean 50.06, SD 24.50 vs mean 64.47, SD 23.04 s; mean difference 14.41 s, 95% CI 2.12 - 26.70 s; $P=.048$), indicating improved dynamic balance. Fear of falling did not differ significantly between walker conditions (mean 31.56, SD 9.58 vs mean 32.91, SD 10.37; mean difference 1.35, 95% CI −3.81 to 6.51; $P=.62$).

Conclusions: A smart wheeled walker integrating real-time physiological monitoring and fall detection significantly improved walking efficiency and dynamic balance during short-term supervised testing in community-dwelling older adults. These findings support the potential clinical value of digital health–enabled mobility aids. Further longitudinal studies conducted in real-world settings are warranted to evaluate long-term mobility, fall prevention, independent use, and comprehensive device safety.

Introduction

Over the past decade, rapid global demographic aging has posed significant challenges to public health systems. By 2050, the global population aged 60 years and older is projected to reach approximately 2.1 billion, marking a dramatic rise in demand for older adult care and preventive strategies. Mobility impairments and balance disorders are key contributors to fall risk in older adults, with nearly one-third of community-dwelling seniors experiencing at least 1 fall annually—a proportion that increases to approximately 50% for those aged over 80 years [1,2]. Falls among older adults not only precipitate functional decline and loss of independence but are also a leading cause of injury-related mortality in this population [3].

In addition to biomechanical limitations, physiological responses during ambulation, such as elevated heart rate (HR) and increased oxygen consumption, have been shown to rise significantly among older adults with impaired mobility [4]. These responses reflect greater cardiovascular and muscular effort required for walking, which may contribute to fatigue and instability. A higher physiological cost of walking has also been associated with reduced gait efficiency and a greater risk of falls, particularly among frail individuals. Real-time monitoring of HR and oxygen saturation (SpO_2) during the use of a walker may thus serve as a meaningful indicator of exertion and functional capacity, enabling targeted interventions to optimize mobility assistance and reduce physiological strain [5]. Among current clinical strategies, the use of mobility aids such as wheeled walkers has proven effective in enhancing gait stability and reducing musculoskeletal burden [6,7]. Older adults using wheeled walkers exhibited significantly improved backward walking performance, including higher speed, greater step frequency, and fewer steps, indicating better motor control and energy efficiency [8]. The type of walking aid used can influence walking performance and physiological energy cost in older adults. These findings reinforce the importance of wheeled walkers in supporting older adults with compromised mobility [9].

Despite their benefits, traditional wheeled walkers have notable limitations related to maneuverability, brake use, and navigation in challenging situations, such as negotiating obstacles, slopes, and doorways [10,11]. Two-wheeled walkers were associated with a higher mean Physiological Cost Index (PCI) and lower gait speed than four-wheeled walkers, suggesting that walker configuration may influence functional walking performance in older adults [12]. Moreover, lateral falls during turning were more frequent among 2-wheeled walker users, while 4-wheeled walker users experienced more backward falls during weight shifting [13]. These incidents highlight the persistent risk of falls even when assistive devices are used, often due to device limitations such as poor maneuverability and inadequate lateral stability. Advanced walker designs have sought to address these challenges. An instrumented 4-wheeled rollator incorporating load cells, pressure-sensing insoles, and 3D motion capture was developed to objectively assess user stability and device loading during different walking scenarios. These findings underscore the need for assistive technologies that can accommodate the complex mobility demands encountered by older adult users [14].

Although previous studies have reported the development and technical capabilities of smart walker technologies, evidence regarding their effects on walking efficiency, dynamic balance, physiological responses, and fear of falling in community-dwelling older adults remains limited [15,16]. Moreover, few randomized crossover studies have directly compared a smart wheeled walker with a conventional wheeled walker under supervised clinical conditions [16]. To address these knowledge gaps, we developed a novel smart wheeled walker integrating safety features, ergonomic adjustability, and physiological monitoring capabilities. The smart wheeled walker integrates 4 complementary functional components. First, the ergonomic frame, height-adjustable handles, freely rotating wheels, and braking mechanism were designed to improve maneuverability, walking efficiency, and dynamic balance. Second, the integrated HR and SpO_2 monitoring system provides real-time physiological information to support assessment of the physiological cost of walking and cardiopulmonary responses during ambulation. Third, the tilt sensor–based fall detection system and mobile alert function enhance safety monitoring by notifying caregivers when excessive tilt or a fall is detected. Finally, the foldable and portable design was intended to facilitate transportation and storage of the device. These design features may support future implementation of smart mobility technologies, although their real-world usability and acceptability were not evaluated in the present study. HR monitoring is particularly relevant to the present study because the PCI, the primary outcome measure of walking efficiency, is calculated from the difference between walking HR and resting HR divided by walking speed. Consequently, continuous HR monitoring provides the physiological data required for objective estimation of the physiological cost of walking during functional ambulation [17]. In addition, SpO_2 monitoring serves as an adjunct physiological safety indicator for monitoring cardiopulmonary responses during walking. These monitoring functions support physiological assessment and safety monitoring but are not intended to directly improve walking efficiency, dynamic balance, or fear of falling. Rather, improvements in walking efficiency and dynamic balance are more likely attributable to the walker's ergonomic design, height adjustability, maneuverability, and braking mechanism, while the physiological monitoring and fall detection functions provide additional clinical information to support safer mobility assessment and use [15-17]. Previous studies have demonstrated the feasibility of smart walker technologies and physiological monitoring systems in supporting mobility assessment among older adults. However, these studies evaluated different walker designs, sensor systems, walking tasks, and outcome measures, making direct comparisons difficult. Despite these promising technological advances, high-quality comparative clinical evidence evaluating the effectiveness of smart wheeled walkers remains limited, particularly randomized crossover studies assessing both functional and physiological outcomes under standardized supervised conditions.

XSL•FO
RenderX

Therefore, this randomized crossover trial aimed to compare walking efficiency, dynamic balance, physiological responses, and fear of falling between a smart wheeled walker with integrated physiological monitoring and fall detection and a standard wheeled walker during supervised use among community-dwelling older adults.

Methods

Development Process of the Smart Wheeled Walker

Step 1: Structural and Ergonomic Design

Smart Wheeled Walker

The smart wheeled walker was engineered with a lightweight aluminum alloy frame to provide structural stability while minimizing the physical effort required during ambulation. The device weighed approximately 6.9 kg and supported users weighing up to 120 kg. It featured a compact foldable design (51 cm × 59.6 cm × 86.6 cm) and 4 multidirectional wheels (2 front and 2 rear) to enhance maneuverability during walking. The frame was constructed from SUS-304 stainless steel hollow tubing (1-inch diameter, 1 mm thickness) to ensure durability while maintaining a lightweight structure. The handle height was adjustable to three levels (78 - 88 cm), allowing users to maintain approximately 20°-30° of elbow flexion during ambulation, an ergonomic position associated with reduced upper-limb loading and improved walking efficiency. The walker incorporated a foam-cushioned seat with a backrest and underseat storage to enhance user comfort during rest periods. Dual hand-operated brakes provided both speed control during walking and secure wheel locking while seated. These structural and ergonomic features were designed to provide mechanical characteristics comparable to those of the standard wheeled walker used in this study while incorporating additional physiological monitoring and fall detection functions.

Standard Wheeled Walker (Comparator)

The comparator was a commercially available 4-wheeled rollator with a lightweight aluminum alloy frame. The device weighed 7.2 kg and supported users weighing up to 100 kg. Its overall dimensions were 61 cm × 70 cm × 89 cm when unfolded and 61 cm × 40 cm × 104 cm when folded. The walker was equipped with four 8-inch polyvinyl chloride (PVC) wheels, adjustable-height handles (78 - 89 cm), and a foldable frame to facilitate transportation and storage. The seating system consisted of a foam-cushioned seat (35 × 32 cm) with a backrest to provide resting support during ambulation. A dual hand-operated braking system enabled speed control during walking and wheel locking while seated. The standard wheeled walker was selected because its fundamental mechanical characteristics, including the lightweight frame, 4-wheel configuration, adjustable handle height, braking mechanism, foldable design, and seating structure, were comparable to those of the smart wheeled walker. Unlike the smart wheeled walker, the standard device did not incorporate real-time physiological monitoring, fall detection, or mobile alert functions.

Step 2: Integration of Smart Fall Detection and Alert System

The walker is embedded with a high-precision tilt sensor (accuracy ±1.5°) capable of detecting deviations in real time. When tilt exceeds 30°—an angle validated in the fall biomechanics literature as indicative of instability—a 2-tier alert protocol is activated:

1. A 90 dB audible alarm is emitted to draw attention from nearby individuals.
2. A mobile notification system transmits alerts via SMS and the LINE app to preregistered caregivers or family members.

This system was validated in a lab-controlled environment using a standardized mannequin drop test, replicated across multiple angles and surfaces. Sensor reliability was cross-verified with external motion capture systems (Vicon, Oxford Metrics) and achieved 96% detection accuracy across 30 trials.

Step 3: Physiological Monitoring Module

To assess exertional load, the walker integrates a commercially calibrated photoplethysmography (PPG) sensor and a pulse oximeter (certified ISO 80601-2-61). The system continuously monitors:

- HR (beats per minute [bpm])
- Peripheral SpO_2 (%)

Real-time physiological data are displayed on a 2.4-inch OLED (organic light-emitting diode) interface in large, high-contrast fonts, allowing immediate feedback for users and clinicians. Sensor accuracy was benchmarked against a validated fingertip pulse oximeter (Masimo Radical-7) and showed a mean absolute error of less than ±2 bpm (HR) and ±1.8% (SpO_2), consistent with clinical-grade standards.

All instrumentation underwent repeated calibration and testing in both static and dynamic conditions (eg, walking on a treadmill at 1.0 - 1.5 m/s). A pilot usability study (n=10 older adults) confirmed signal stability during typical community-based ambulation.

Step 4: Testing of the Developed Smart Wheel Walker

Participants

This study included 30 community-dwelling older adults aged between 65 and 80 years, residing in Chonburi Province, Thailand. Participants were recruited from local communities in Chonburi Province, Thailand, through community announcements, village health volunteers, and referrals from local health care personnel. Individuals who expressed interest were invited to the Physical Therapy Laboratory, Burapha University, where eligibility screening was conducted according to the predefined inclusion and exclusion criteria. Eligible participants received verbal and written information about the study, provided written informed consent, and were subsequently enrolled in the trial. Eligibility criteria required that participants be capable of walking independently and performing activities of daily living without assistance. To ensure a mild balance deficit, the Timed Up and Go (TUG) test was administered, and only individuals with scores greater than 13.5 seconds were

XSL•FO
RenderX

enrolled. Exclusion criteria included a diagnosis of any neurological condition that impaired gait and orthopedic or musculoskeletal surgery of the upper or lower limbs within the past 3 months. Additional exclusions were uncorrectable visual impairments such as cataracts or diabetic retinopathy and any severe cardiovascular or musculoskeletal disorders that could interfere with safe ambulation. The study adhered to ethical guidelines, including the right to withdraw at any time and the protection of participant confidentiality. Following enrollment, participants were assigned to the intervention sequence in this randomized crossover trial. After completing the first walking condition, participants rested for 30 minutes to minimize carryover effects before using the alternate walker. The order of walker use was counterbalanced across participants to control for potential sequencing bias.

Study Design

This study used a single-blind randomized crossover trial design in which the outcome assessor was blinded to the allocation sequence. Randomization was performed by an independent researcher using a computer-generated random allocation sequence created with the RAND function in Microsoft Excel. Allocation concealment was maintained using sequentially numbered, sealed, opaque envelopes. Outcome assessments were conducted by a separate blinded assessor who was not involved in the randomization process or intervention administration. Because of the visible differences between the smart wheeled walker and the standard wheeled walker, participant blinding was not feasible. Participants were randomly assigned to begin with either the smart wheeled walker or the standard wheeled walker. After completing the first intervention, participants crossed over to the alternate walker following a 30-minute washout period to minimize potential carryover effects. The washout period was selected to allow physiological recovery following the brief 20-m walking task, particularly recovery of HR before the second assessment. Before formal testing, all participants completed a familiarization session with both walkers. Standardized instructions on the correct use of each device were provided, and participants practiced walking with both walkers before outcome measurements were performed. The short walking distance and self-selected comfortable walking speed were considered unlikely to induce substantial fatigue or persistent physiological effects that could influence the subsequent assessment. This randomized crossover trial was designed to compare the short-term effects of a smart wheeled walker and a standard wheeled walker under standardized, supervised clinical conditions. The primary objective was to evaluate walking efficiency using the PCI. Secondary objectives were to assess dynamic balance and fear of falling. HR and walking speed were recorded to support the calculation and interpretation of PCI rather than as independent confirmatory outcomes. This study was not intended to evaluate long-term clinical effectiveness, independent community use, or real-world implementation. The study was reported in accordance with the CONSORT-eHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (Checklist 1).

Ethical Considerations

This study was approved by the Burapha University Research and Innovation Administration Committee (IRB1-115/2567). The trial was prospectively registered in the Thai Clinical Trials Registry (TCTR20250302008). The study conformed to the ethical standards set forth in the Declaration of Helsinki. All data collection was conducted between April and May 2025 at the Physical Therapy Laboratory of Burapha University, Thailand. Written informed consent was obtained from all participants before enrollment. Participants were informed that participation was voluntary and that they could withdraw from the study at any time without consequences. All data were deidentified before analysis and stored securely to maintain participant confidentiality. Participants received reimbursement for travel expenses but did not receive any additional financial compensation or incentives for participation.

Sample Size Estimation

The sample size was determined using G*Power version 3.1.9.2. The calculation was based on the primary outcome (PCI). An effect size of 0.60 was estimated from preliminary paired PCI data obtained from 10 community-dwelling older adults who completed walking assessments using both the smart wheeled walker and the standard wheeled walker. Assuming a 2-tailed paired *t* test, a significance level (α) of .05, and a statistical power ($1-\beta$) of .80, the estimated minimum sample size was 24 participants. To account for an anticipated 20% attrition rate, the target sample size was increased to 30 participants.

Experimental Procedure

Participants attended an orientation session 1 day prior to testing at the Faculty of Allied Health Sciences, Burapha University. The procedures were explained, and participants practiced adjusting walker height to the level of the greater trochanter, maintaining elbow flexion between 20° and 30°. They were also familiarized with walking using both a standard wheel walker and a smart wheeled walker.

On the testing day, participants were fitted with a Polar FT7 HR monitor (Polar Electro Oy). Resting HR was recorded over 5 minutes before walking trials. Participants then walked 20 m at a normal pace using one of the 2 walker types, with HR recorded every 30 seconds during walking and a 5-minute seated recovery period. Walking speed was also measured. After a 30-minute rest, participants repeated the protocol with the alternate walker. Walker order was randomized.

Outcome Measurements

Primary Outcome: Walking Efficiency

Walking efficiency was quantified using the PCI, calculated as follows: PCI (beats/m) = (HR during walking – Resting HR)/Average walking speed, where HR is expressed in bpm and average walking speed in meters per minute (m/min). A lower PCI value reflects a more efficient gait pattern. This metric was applied to compare energy expenditure during ambulation with both the smart-wheeled walker and the standard walker, thereby reflecting the physiological cost of walking [18]. The PCI was the prespecified primary outcome and served as the principal confirmatory end point. HR and walking speed were

XSL•FO
RenderX

measured to support the calculation and physiological interpretation of PCI and were not considered independent confirmatory outcomes. Dynamic balance (Expanded Timed Up and Go [ETUG]) and fear of falling (Falls Efficacy Scale-International [FES-I]) were evaluated as prespecified secondary outcomes.

Secondary Outcomes

Dynamic Balance

Dynamic balance was evaluated using the ETUG test.

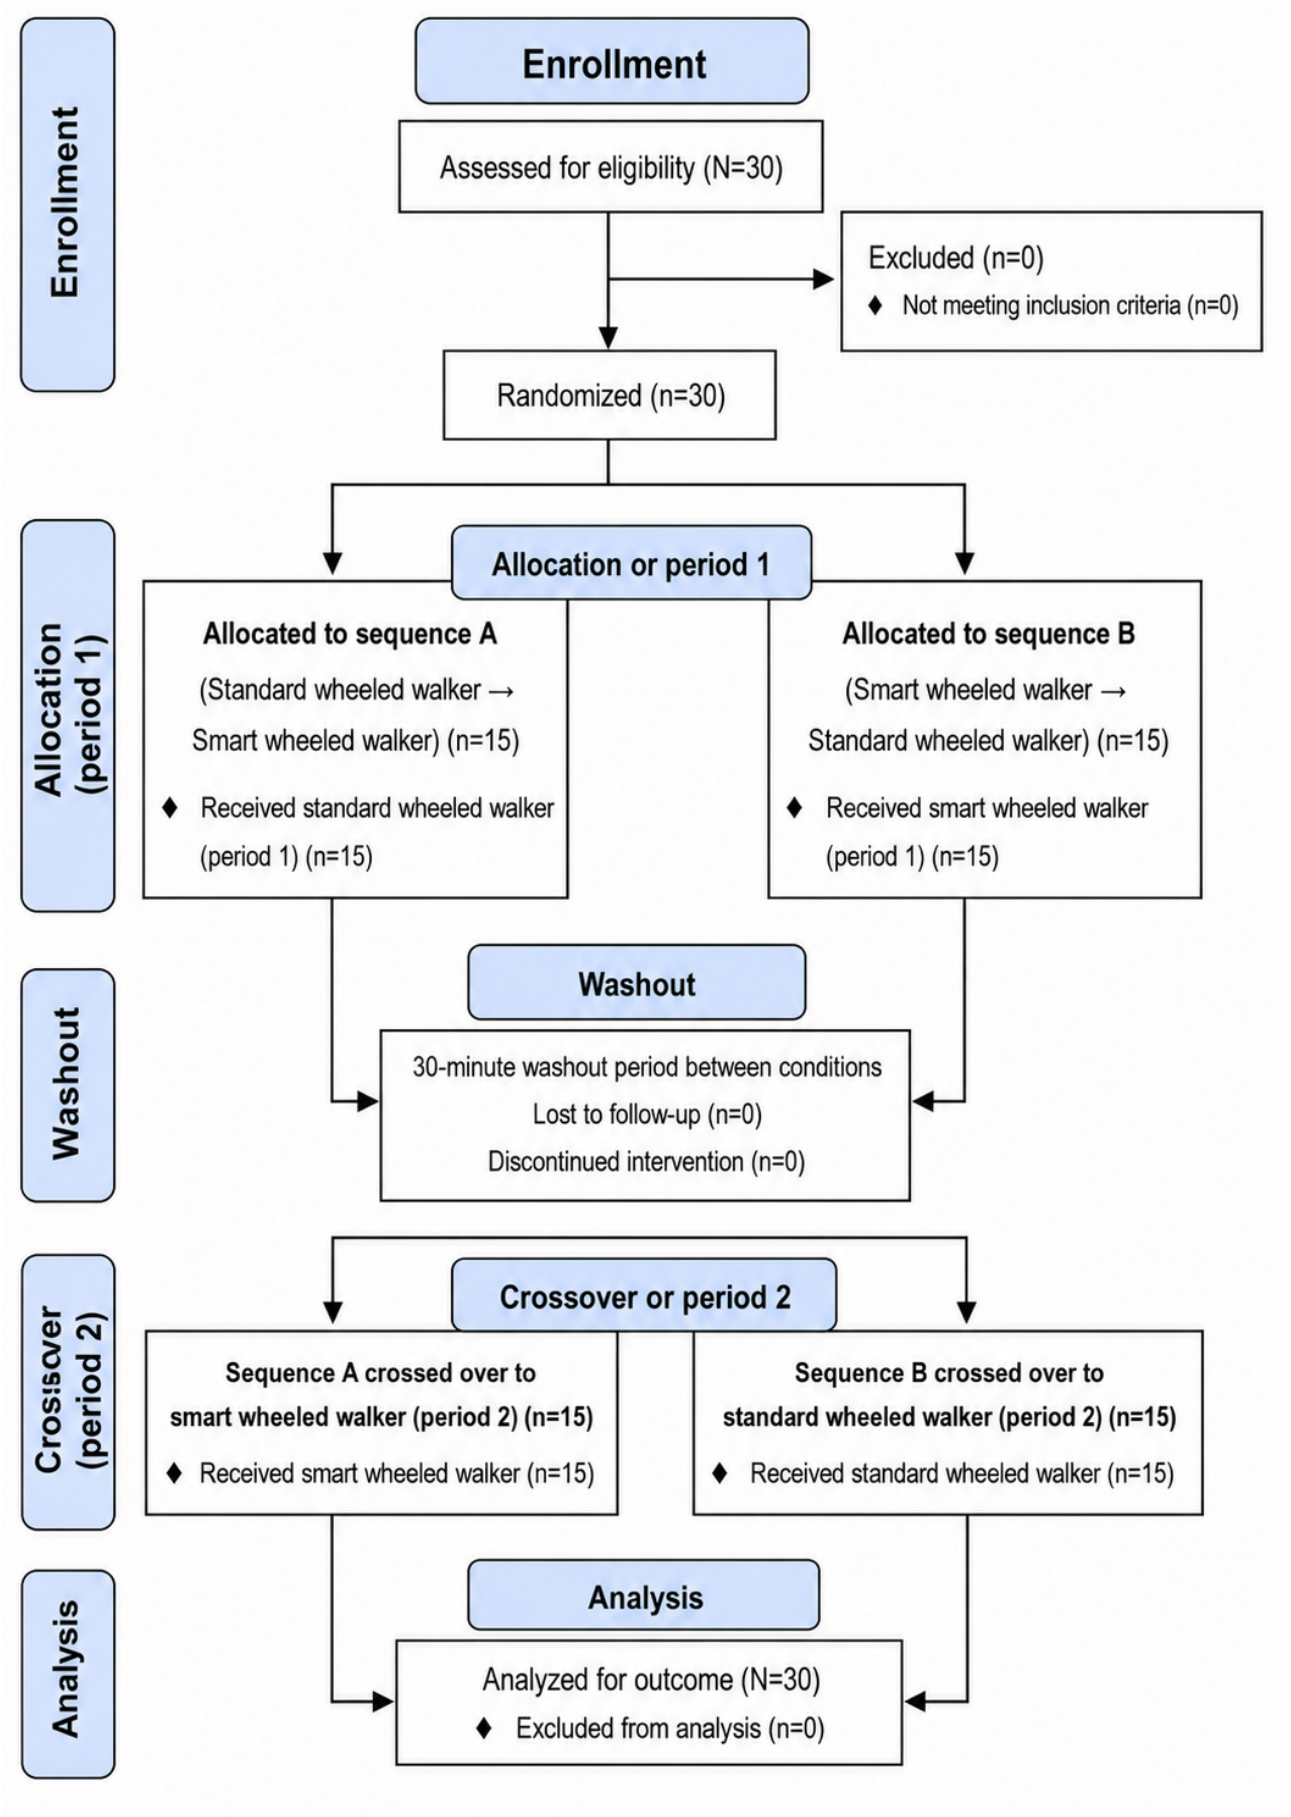
Participants were instructed to rise from a chair, walk a 20-m distance using either walker, circle a designated marker, and return to sit. The time to complete the task was recorded in seconds [19].

Fear of Falling

Fear of falling was assessed using the Thai version of the FES-I, which was adapted and validated by Thiamwong based on the original instrument developed by the Prevention of Falls Network Europe (ProFaNE) [20]. The scale includes 16 items that assess concern about falling during a range of physical and social activities, from basic daily tasks to more demanding functions. Participants rated their concern on a 4-point Likert scale: 1 (not at all concerned), 2 (somewhat concerned), 3 (fairly concerned), and 4 (very concerned). Total scores range from 16 to 64. Scores of 16 to 21 indicate low concern about falling, 22 to 27 reflect moderate concern, and 28 to 64 represent high concern. This scale has been widely used to evaluate fall-related self-efficacy among older adults in community and clinical settings.

Data Analysis

All statistical analyses were conducted using SPSS (SPSS Inc.). Descriptive statistics were used to summarize demographic data. The Shapiro-Wilk test was used to assess the normality of outcome variables. Paired *t* tests were used to compare resting HR, walking HR, average walking speed, PCI, ETUG performance, and fear of falling between the 2 walker conditions for normally distributed data. In addition, a repeated-measures ANOVA was performed as a supplementary analysis for the randomized crossover design. The model included walker condition (smart wheeled walker vs standard wheeled walker) and period (first vs second assessment) as within-participant factors and sequence (smart-standard vs standard-smart) as a between-participant factor, with participants treated as the repeated subject. Sequence and period effects were examined to indirectly assess potential residual carryover effects. Because of the relatively small sample size, these analyses were considered exploratory and were interpreted with caution. A 2-sided *P* value of <.05 was considered statistically significant.



Results

Overview

Figure 1 presents the CONSORT 2010 flow diagram illustrating the flow of participants through enrollment, randomization, allocation to intervention sequence, crossover, follow-up, and analysis. A total of 30 community-dwelling older adults were enrolled and completed both intervention conditions. No participants were lost to follow-up or excluded from the final analysis.

Participant Characteristics

Thirty older adults participated in the study, including 7 (23.33%) men and 23 (76.67%) women. The mean age was 69.83 (SD 3.51) years. The average height and weight were 158.40 (SD 8.29) cm and 60.41(SD 10.99) kg, respectively, yielding a mean BMI of 24.20 (SD 3.56) kg/m². Functional mobility was assessed using the ETUG test, with an average completion time of 13.98 (SD 0.85) seconds (Table 1).

Table . Baseline characteristics of the participants (N=30).

Variable	Values
Sex, n (%)	
Male	7 (23.33)
Female	23 (76.67)
Age (y), mean (SD)	69.83 (3.51)
Weight (kg), mean (SD)	60.41 (10.99)
Height (cm), mean (SD)	158.40 (8.29)
BMI (kg/m²), mean (SD)	24.20 (3.56)
ETUG[a] test (3 m, seconds), mean (SD)	13.98 (0.85)

[a]ETUG: Expanded Timed Up and Go.

Primary Outcome: Walking Efficiency

The analysis showed that HR measurements taken before (*P*=.92), during (*P*=.55), and after walking (*P*>.99) did not differ significantly between the smart wheeled walker and standard wheel walker conditions. However, participants demonstrated a significantly faster average walking speed over the 20-m course when using the smart wheeled walker (*P*<.001). In addition, the PCI, which reflects the energy cost of walking, was significantly lower in the smart wheeled walker condition compared to the standard wheel walker (*P*=.02), indicating more efficient ambulation with the smart device.

Secondary Outcomes

Dynamic Balance

Dynamic balance, evaluated through the ETUG test, showed a statistically significant improvement when participants used the smart wheeled walker. The time required to complete the TUG test was notably shorter with the smart device than with the standard walker (*P*=.048), indicating better balance and mobility performance.

Fear of Falling

The findings of this study indicated that participants who walked with the smart wheeled walker reported lower levels of fear of falling compared to those who used the standard wheel walker. However, the difference between the 2 groups did not reach statistical significance (*P*=.62; Table 2).

Table . Comparison of heart rate (HR), walking efficiency, average speed, and dynamic balance between standard walker and smart wheel walker.

Variables	Standard wheel walker (n=30), mean (SD)	Smart wheel walker (n=30), mean (SD)	Difference among groups (95% CI)	*P*[a] value
Walking efficiency (PCI[b], beats/m)	0.69 (1.23)	0.36 (0.38[c])	0.33 (0.06 to 0.60)	.02
Resting HR (beats/minute)	71.72 (11.36)	71.35 (11.80)	0.37 (−5.61 to 6.35)	.92
Walking HR (beats/minute)	85.47 (11.34)	83.47 (11.89)	2.00 (−4.00 to 8.00)	.55
Postwalking HR (beats/min)	73.23 (12.01)	73.20 (12.62)	0.03 (−6.33 to 6.39)	>.99
Average walking speed (20 m, m/min)	18.14 (14.55)	28.77 (11.94[c])	−10.63 (−17.51 to −3.75)	<.001
Dynamic balance (ETUG[d], seconds)	64.47 (23.04)	50.06 (24.50[c])	14.41 (2.12 to 26.70)	.048
Fear of falling (scores)	32.91 (10.37)	31.56 (9.58)	1.35 (−3.81 to 6.51)	.62

[a]*P*<.05 was considered statistically significant.

[b]PCI: Physiological Cost Index.

[c]Significantly different between walker types.

[d]ETUG: Expanded Time Up and Go.

XSL•FO
RenderX

Additional crossover analyses demonstrated no significant sequence effects for PCI (*P*=.62), ETUG (*P*=.54), walking speed (*P*=.71), or FES-I (*P*=.83). Similarly, no significant period effects were observed for any study outcome (all *P*>.05). These findings indicate that the order of walker administration and testing period did not materially influence the treatment comparisons between the smart wheeled walker and the standard wheeled walker.

Discussion

Principal Findings

This study investigated the comparative impact of a smart wheeled walker and a standard walker on various aspects of mobility and user experience in older adults. The smart wheeled walker, which incorporates advanced functions, including adjustable height, multidirectional wheels, biometric feedback, and real-time fall alert capabilities, was associated with favorable short-term outcomes in several mobility-related measures under supervised testing conditions.

The smart wheeled walker was associated with improved walking efficiency, as reflected by a significantly lower PCI under the supervised conditions of the present study (0.36 beats/m), compared with the standard wheeled walker (0.69 beats/m). This value was lower than that previously reported for conventional wheeled walkers (1.23 beats/m) [12], although direct comparisons between studies should be interpreted with caution because of differences in study populations and experimental protocols. This improvement is likely attributable to multiple design features aimed at optimizing mechanical advantage and reducing muscular workload. The device's adjustable height mechanism allowed users to maintain an elbow flexion angle of approximately 30°, a position that supports optimal force transfer through the upper extremities during assisted gait. This alignment may have minimized unnecessary recruitment of the shoulder depressor muscles, such as the latissimus dorsi and triceps brachii, particularly in taller individuals [2], resulting in reduced fatigue and more efficient propulsion. Additionally, the multidirectional wheels and lightweight aluminum frame likely contributed to smoother gait cycles by decreasing friction and minimizing the need for abrupt deceleration or manual lifting of the device. These factors together may have reduced the cumulative metabolic demand during ambulation. Although the mean HR during walking was not statistically different between the groups, participants using the smart wheeled walker exhibited slightly lower average HRs (83.47, SD 11.89 bpm vs 85.47, SD 11.34 bpm). This trend may reflect a lower cardiovascular load, secondary to the improved mechanical efficiency and reduced physical exertion required to maneuver the device. These physiological findings are in line with prior evidence demonstrating that walker design can influence energy expenditure and cardiopulmonary response during walking [1].

The results of this study suggest that participants demonstrated better dynamic balance while using the smart wheeled walker than the standard wheeled walker, as reflected by ETUG performance under supervised testing conditions. Participants using the smart wheeled walker completed the test in less time (50.06, SD 24.50 s) than those using the standard wheeled walker (64.47, SD 23.04 s), suggesting superior walking efficiency and postural control. These findings align with previous research that demonstrated that wheeled walkers can reduce energy expenditure and support faster straight-line walking in older adults [9]. Previous studies have also reported that wheeled walkers improve balance and stability during ambulation [6]. However, the present study did not evaluate fall incidence; therefore, the potential effect on fall prevention remains to be confirmed in future longitudinal studies [6]. The current study findings are also consistent with previous evidence suggesting that wheeled walkers help prevent physical decline by enabling safe and sustained physical activity in older individuals. Importantly, the smart wheeled walker used in this study featured a height-adjustable frame with 3 levels, allowing users to begin walking from an ergonomically optimal elbow flexion angle of approximately 30° [21]. This positioning reduces arm fatigue and supports more natural and stable movement. Previous research has also demonstrated that height-adjustable walkers are associated with improved balance during ambulation [22]. Additionally, the smart wheeled walker incorporated front and rear wheel locking mechanisms, enhancing safety during use. These braking systems likely provided users with greater control during transitions and when navigating turns or uneven movements. These braking systems may have contributed to improved maneuverability and perceived stability during walking tasks, which may contribute to safer mobility during supervised walking tasks. The potential effect on fall prevention requires confirmation in longitudinal studies. Taken together, these findings suggest that the smart wheeled walker may have the potential to support mobility in older adults under supervised conditions. Because ETUG was a prespecified secondary outcome and no formal adjustment for multiple comparisons was performed, these findings should be interpreted as supportive rather than confirmatory evidence. Therefore, larger randomized controlled trials with long-term follow-up are required to confirm these findings.

In this study, the average score on the fear of falling scale was slightly lower among participants using the smart wheeled walker compared to those using the standard walker, although the difference was not statistically significant. However, the numerical trend observed in the smart wheeled walker condition may warrant further investigation in studies with larger sample sizes and longer follow-up. The smart walker included features such as a lightweight aluminum frame, adjustable handles, 4 rotatable wheels, a built-in seat, and a dual-braking system. Furthermore, it incorporated intelligent capabilities including a tilt sensor that detected deviations greater than 30° and transmitted alerts through mobile messaging apps. The integrated display of real-time HR and SpO_2 may also have provided additional reassurance to users and caregivers. These design features likely enhanced the sense of psychological security, particularly in individuals who ambulate independently or reside alone. Previous studies have suggested that automatic fall detection systems and health-monitoring functions may reduce anxiety related to safety. However, the present study did not evaluate the real-world performance of the fall detection and alert system during actual fall events. Previous research has

XSL•FO
RenderX

highlighted the association between elevated fear of falling and decreased physical and social engagement, which may in turn increase the risk of functional decline and actual falls [23]. Although the difference was not statistically significant, the numerical trend observed in the present study may warrant further investigation in adequately powered studies with longer follow-up to determine whether the smart wheeled walker has a meaningful effect on fear of falling, particularly among older adults at increased risk of falls.

This study has several important limitations. First, the inclusion criteria did not exclude participants with chronic conditions or those taking medications that could influence cardiovascular responses, such as beta-blockers. These factors may have affected HR data and walking performance outcomes. Future research should consider refining the exclusion criteria to control for medical conditions and pharmacological influences that could confound physiological measurements. Second, the number of previous falls among participants was not documented. Since fall history is a known predictor of mobility confidence and functional balance, its absence limits the ability to interpret fear of falling and balance-related outcomes fully. Third, the study was conducted in a controlled indoor setting with uniform flooring. This limits ecological validity, as real-world environments often include uneven surfaces, curbs, or visual distractions that challenge gait and balance. Future studies should assess device performance across diverse environmental conditions to better reflect everyday use. Fourth, no measures of oxygen consumption or electromyographic activity were included. Incorporating such physiological metrics would allow for a more comprehensive understanding of energy expenditure and muscle activation patterns during device use. Fifth, the gender distribution in this sample was notably imbalanced, with a higher number of female participants. Given known sex-related differences in gait characteristics, strength, and perceptions of fall risk, this imbalance may have influenced the study's findings. Future studies should strive for more balanced recruitment or conduct stratified analyses to better understand sex-specific responses to assistive technologies. Sixth, the smart wheeled walker and the standard wheeled walker differed not only in their smart monitoring and fall alert functions but also in several mechanical and ergonomic characteristics, including frame design, wheel configuration, and adjustability. Therefore, the observed differences between the 2 devices cannot be attributed solely to the smart monitoring and alert functions, as the mechanical and ergonomic differences between the devices may also have influenced walking performance and user outcomes. In addition, although the smart wheeled walker incorporates fall detection and mobile alert functions, the present study did not evaluate the real-world performance of these features during actual fall events or independent community use. Although the smart wheeled walker demonstrated promising short-term benefits under supervised conditions, several factors should be considered before its implementation in real-world settings. Older adults may differ in digital literacy, cognitive and sensory abilities, and their willingness to use technology-assisted devices. Caregiver support may be necessary for some users, particularly when responding to remote alerts or assisting with device operation. In addition, privacy and data security should be carefully addressed when transmitting health-related information. Future studies should evaluate the long-term usability, acceptability, safety, and implementation of the smart wheeled walker during independent home and community use in more diverse older adult populations. In addition, the present study did not systematically collect data on usability, user experience, or comprehensive safety outcomes, including adverse events during prolonged use. These aspects should be incorporated into future studies to provide a more comprehensive evaluation of the smart wheeled walker. Seventh, the study assessed only short-term use of each walker type. Longitudinal follow-up would be valuable for evaluating sustained effects on physical performance, fall incidence, and user adherence over time. The randomized crossover design enabled each participant to serve as his or her own control, thereby reducing interindividual variability. Additional crossover analyses demonstrated no significant sequence or period effects, suggesting that the order of walker administration and testing period did not materially influence the study outcomes. However, because of the relatively small sample size, these findings should be interpreted with caution and do not completely exclude the possibility of residual sequence or carryover effects. Moreover, participant familiarization before testing, randomized and counterbalanced allocation, and a 30-minute washout period were implemented to minimize potential carryover, learning, and fatigue effects. Nevertheless, because the study was conducted during a single supervised testing session, residual carryover or learning effects cannot be completely excluded. Future crossover studies with larger sample sizes and longer follow-up should further evaluate these potential influences. In addition, the generalizability of the present findings should be interpreted with caution. The study included only community-dwelling older adults aged 65 to 80 years, with a predominance of female participants, and all assessments were conducted under supervised laboratory conditions. Therefore, the findings may not be generalizable to frailer older adults, institutionalized individuals, people with cognitive impairment, or unsupervised community settings. Future studies should include more diverse populations and evaluate the performance of smart wheeled walkers in real-world environments to improve the external validity of the findings. Finally, this randomized crossover trial involved a relatively small sample size and a single supervised testing session. Therefore, the findings should be interpreted as evidence of short-term performance under supervised conditions rather than definitive evidence of long-term clinical effectiveness or real-world functional benefits. Future adequately powered randomized controlled trials with extended follow-up in community settings are warranted to confirm these findings and evaluate the long-term effectiveness, safety, and user adherence of the smart wheeled walker.

Conclusions

This randomized crossover clinical trial showed that the smart wheeled walker was associated with improved walking efficiency and dynamic balance under supervised testing conditions when compared with a standard wheeled walker. Cardiovascular responses and fear of falling did not differ significantly between walker conditions. Because the smart wheeled walker was evaluated as an integrated device, the

XSL•FO
RenderX

independent contribution of individual design features could not be determined. Further randomized controlled trials with larger and more diverse samples, long-term follow-up, and real-world evaluation are needed to evaluate the individual and combined effects of specific design features and to further establish the clinical effectiveness and practical applicability of smart wheeled walkers for older adults.

Abstract

Background: With the rising prevalence of aging worldwide, there is a necessity for reliable and frequent assessments of older individuals' health status to manage and potentially prevent age-related complications. Digital health technologies (DHTs), such as wearable devices, provide an opportunity to gather objective, continuous, and unobtrusive measurements, enabling effective health management in everyday life.

Objective: We aimed to evaluate the relationship between digital endpoints and frailty, nutritional status, and patient-reported outcomes (PROs) in older individuals, as well as quantified their compliance and comfort with DHTs.

Methods: In two cross-sectional studies, namely the Geriatric Anorexia Studies 1 and 2, including three in-clinic visits and 2-3 weeks of at-home monitoring, 94 participants (mean age 72.98 years, SD 6.28 years) were stratified based on their frailty status (n=39, 41%, nonfrail; n=45, 48%, prefrail; and n=10, 11%, frail) and nutritional status (n=70, 74%, with normal nutrition and n=24, 26%, at risk for malnutrition), as assessed in a clinical setting using the Fried Frailty Score and the Simplified Nutritional Appetite Questionnaire, respectively. We remotely monitored older adults using different DHTs. At home, participants were monitored with a wrist accelerometer for physical activity, continuous glucose monitoring (CGM) for glucose concentration, a digital body scale for weight and body composition, and a digital nutritional scale for meal tracking. Compliance with devices was assessed via wear time and correct at-home usage, while comfort was evaluated using questionnaires. The association between digital endpoints and frailty/nutritional status was investigated via linear regression, followed by ANOVA, and the relationship between digital endpoints collected at home and PROs was evaluated via Spearman's ρ. Weight and body composition were also assessed during in-clinic visits with a research-grade scale, used to validate the at-home digital body scale measurements, via the intraclass correlation coefficient, Pearson's R, and Bland-Altman plots with mean bias.

Results: Physical activity digital endpoints collected at home were significantly different across frailty and nutritional groups and significantly correlated with self-reported appetite, fatigue, and physical function (eg, for mean daily activity in the maximum 60 minutes of activity, ρ=0.28, –0.23, and 0.47, respectively). More than 80% of participants reported that all devices were mostly to very acceptable to wear/use: 95% (88/93) for the body scale, 86% (43/50) for CGM, 80% (40/50) for the nutrition scale, and 91% (84/93) for the wrist accelerometer. Compliance ranged from 60% of monitoring days for the digital nutrition scale to 90% for the wrist accelerometer.

Conclusions: Physical activity digital endpoints show clear prognostic significance for frailty and malnutrition in older individuals and reflect self-reported measures. DHTs can be reliably deployed at home for older individuals to measure their physical activity, weight and body composition, glucose concentration, and meal intakes, thus enabling patient-centric, data-centric clinical trials.

Introduction

Aging is a worldwide phenomenon that is rapidly gaining attention due to the increasing prevalence of older adults and the profound impact it has on individuals and society [1,2]. Aging is associated with a wide variety of comorbidities, such as reduced appetite, undernutrition with associated weight loss and changes in body composition, decreased exercise capacity, and frailty [3]. These conditions are commonly referred to as anorexia of aging (AoA) [4-7].

To diagnose and monitor age-related diseases, typical assessments include, but are not limited to, physical function, weight, and appetite [8]. These assessments are traditionally performed during in-clinic visits using nonscalable devices (eg, research-grade scales to measure weight and body composition) and questionnaires (eg, the Fried Frailty assessment [9]). Notably, in-clinic assessments might not reflect the variability observed in daily life [10,11], because the visits are sporadic and limited in time and space, and participants' performance can be affected by the presence of observers [12]. In addition, self-reported assessments inherently lack objectivity, particularly for individuals with cognitive impairments, making comparisons between individuals difficult [6]. Finally, in-clinic visits require individuals to travel to clinical trial sites, which can be burdensome, especially for those with reduced mobility and/or those living in rural areas [13].

To overcome the limitations of traditional assessments of age-related diseases and address the need for objective, remote, and unobtrusive high-frequency measurements, the use of digital health technologies (DHTs) has been explored in the literature [11,14]. DHTs refer to a broad category of tools, platforms, and systems that integrate software, hardware, and data analytics to monitor different aspects of health and support clinical decision-making, enhance health care management, and improve patient engagement [15]. This work focuses on DHTs to monitor age-related conditions: wearable accelerometers, digital body weight and nutrition scales, continuous glucose monitoring (CGM) devices, and smartphone apps, whose applications are described next.

Wearable accelerometers, such as smartwatches and lumbar belts, allow for objective measurements of the variability of physical activity and gait in daily life. Their use in older individuals has been widely explored in the literature, showing their potential to unlock new insights into older adults' frailty and overall health status [16,17].

Digital body scales, deployed in free-living environments, may afford an opportunity to monitor weight and body composition remotely and with more granularity (eg, daily) and to automatically share data with clinical practitioners. This may enable the early detection of weight loss, weight cycling, or sarcopenia, which are associated with disability and mortality in older adults [18,19].

DHTs can also be used to remotely monitor meal intake and glucose concentration, which can indicate alterations in eating behavior, mitigating the risk for malnutrition and potentially preventing the onset of metabolic disorders [20,21]. Handwritten food diaries are often used to report information about meal timings and amounts, but they rely on users' memory to recall the food consumed, and require the burdensome task of estimating portion size, thus lacking accuracy and reproducibility. In addition, they provide unstructured data, requiring time-consuming and error-prone data harmonization prior to analysis [22-24]. To streamline dietary behavior monitoring, digital nutrition scales can be used to automatically pull meal timings from the network and objectively calculate the serving weight [25,26], resulting in standardized data that can be sent in real time to physicians, dietitians, or nutritionists to accelerate their clinical interpretation. The smartphone apps linked to nutrition scales can provide users with additional features, such as reminders at regular time intervals, which increase compliance and data completeness [27], and the integration of food composition databases, which streamlines the calculation of meals' nutritional content. More advanced tools, such as the one proposed by Ryu et al [28], can perform automatic estimation of meals' macronutrient content by leveraging artificial intelligence models to analyze food pictures taken by individuals.

Furthermore, continuous glucose monitoring (CGM) devices represent state-of-the-art systems to track glucose concentration continuously, with wide applications in the diabetes space across different age ranges [29,30]. Although there is evidence for the use of CGM in different disease areas, including obesity [31], eating disorders [32], or following bariatric surgery [33], its application in healthy older individuals has been poorly explored.

The systematic evaluation and early assessment of frailty and malnutrition are crucial to identify individuals at the highest risk for adverse outcomes, allowing the development of individualized care plans, optimization of physical and mental health, and improvement in overall quality of life for the aging population [34]. In this paper, we investigated the use of DHTs to remotely characterize frailty and malnutrition in older adults. For this purpose, we conducted two cross-sectional studies, namely the Geriatric Anorexia Studies 1 and 2 (GAS-1 and GAS-2), in which older individuals, aged 65-96 years, with different frailty and nutritional statuses were monitored both during in-clinic visits and at home with various DHTs: lumbar and wrist accelerometers, a digital body scale, a digital nutrition scale with a smartphone app, and CGM. Our previous study [35] examined the relationship between older individuals' frailty status and digital endpoints of gait and physical activity using GAS-1 data only. This study integrated GAS-1 and GAS-2 data and broadened the scope by exploring digital endpoints of physical activity, glucose concentration, body composition, and meal composition in relation to (1) the effectiveness of physical

XSL•FO
RenderX

activity digital endpoints in distinguishing between frailty and nutritional status and in correlating with self-reported measures and (2) compliance and comfort with DHTs deployed remotely to measure body weight, glucose concentration, and dietary behavior in order to support the design of more patient-centric clinical trials.

Methods

Dataset: Geriatric Anorexia Studies

The dataset used in this manuscript combined data collected in two studies: GAS-1 (NCT04858932), which monitored community-dwelling older adults, and GAS-2 (NCT05211973), which monitored a cohort of older individuals in long-term care (LTC) settings, such as nursing homes or assisted-living facilities. Both studies included three in-person visits at the participant's facility, where traditional assessments were performed, including questionnaires and weight and body composition data collection via research-grade scales, and 2-3 weeks of at-home monitoring, where DHTs were deployed to collect data remotely. Both studies targeted participants aged 65 years or older, with a Montreal Cognitive Assessment (MoCA) score of ≥19. Additional details on the study design and inclusion/exclusion criteria are reported in Multimedia Appendix 1.

Ethical Considerations

Both studies were reviewed and approved by the Boston University Medical Campus and Boston Medical Center Institutional Review Board (IRB #H-40837 and #H-42048). All participants provided written informed consent prior to enrollment into the study. All study procedures were in accordance with the relevant guidelines/regulations, including data privacy and the Declaration of Helsinki. Data transmission protocols were reviewed by the Boston University Information Technology and the IRB for security and privacy. No identifiable data were used to initialize the devices. Secure File Transfer Protocol (sFTP) was used to transfer data between Boston University and Pfizer, following Good Clinical Practice guidelines, Boston University Information Technology, and Spivack Center for Clinical and Translational Neuroscience policies.

DHTs Used in the Two Studies

Physical activity data were collected using the GENEActiv accelerometer (Activinsights Ltd), which was worn on the nondominant wrist. A lumbar accelerometer was used only in GAS-1, and the related gait endpoints have been discussed elsewhere [35].

Weight and body composition measurements were collected using two scales, the Tanita MC-780U scale (Tanita Corporation of America) and the Renpho ES-BR003 body scale (Renpho Joicom Corporation). The former, used only during in-person visits by study staff, is a Food and Drug Administration (FDA)–cleared scale that uses bioelectrical impedance analysis (BIA) from footplate and hand electrodes [36] and stores data on a wired computer. The latter, used both during in-clinic visits and at home, is a cost-effective, rechargeable, consumer-grade scale that uses lower extremity BIA and stores data through a connection to its own app downloaded on the iPhone XR (Apple Inc) provided. Participants were instructed to use the Renpho body scale every day in the morning upon waking.

The Freestyle Libre Pro CGM (Abbott Laboratories) was used only in GAS-1 to automatically measure the glucose concentration every 15 minutes.

Finally, GAS-1 participants were instructed to use the Renpho ES-SNG01-W smart nutrition scale (Renpho, Joicom Corporation), a digital food scale, paired via Bluetooth with the Gennec app, to capture meals' weight and integrate nutritional insights from a food database, helping keep an automatic and comprehensive food diary. As a backup collection system, participants photographed the weight displayed on the scale using the iPhone provided. Participants were required to perform these operations both before and after consuming each meal, including prepackaged meals provided to them by Epicured.

Assessment of Frailty and Nutritional Status

In this research, the Fried Frailty Score (FFS) was used to evaluate frailty. The FFS involves both questionnaires and objective physical performance tasks (ie, unintentional weight loss, self-reported exhaustion, weakness, slow walking speed, and low physical activity), resulting in a total score of 0-5, which is used to stratify individuals in three frailty groups: nonfrail (FFS=0), prefrail (FFS=1-2), and frail (FFS=3-5) [9]. In some studies [35,37], the FFS has also been used to categorize individuals into two robustness groups, robust (FFS=0, ie, nonfrail), and nonrobust (FFS=1-5, ie, combining prefrail and frail).

In this research, the Mini Nutritional Assessment – Short Form (MNA-SF) and the Simplified Nutritional Appetite Questionnaire (SNAQ) were used to evaluate nutritional status. The MNA-SF includes six questions about food intake, recent weight loss, current mobility, psychological stress or acute disease, neuropsychological problems, and the BMI or calf circumference, resulting in a total score of 0-14, indicating malnutrition (≤7), risk for malnutrition (8-11), and normal nutrition (≥12) [38]. The SNAQ is a four-question tool scored using a 5-point Likert-scale also used to evaluate the nutritional status, resulting in a total score of 4-20, where higher scores indicate better appetite. In particular, scores≤14 have been reported to indicate a significant risk for weight loss of >5% within 6 months [39,40] and to be a marker of malnutrition risk in healthy community-dwelling older adults [41].

Patient-Reported Outcomes

Patient-reported outcomes (PROs) were measured during in-clinic visits and at home on paper by participants. Appetite and fatigue PROs were measured daily. The question on appetite was "How would you rate your appetite during the past 24 hours from 0 to 10 (0=no appetite, 10=very good appetite)?," while the fatigue question was "How would you rate your physical fatigue during the past 24 hours from 0 to 10 (0=no fatigue, 10=worst-possible fatigue)?" These questions were developed by Pfizer based on concept elicitation interviews and cognitive debriefing of questions and response options with the population of interest, following the "FDA Patient-Focused Drug Development Guidance Series for Enhancing the Incorporation

XSL•FO
RenderX

of the Patient's Voice in Medical Product Development and Regulatory Decision Making" [42]. Finally, the well-known PROMIS (Patient-Reported Outcomes Measurement Information System) Physical Function 10a was used during the in-clinic visits [43].

Comfort and wearability questionnaires were used at the last visit to gather feedback on the use of DHTs. The questionnaires included 10 items, with rated questions and free-text comments, reflecting what has been already used in previous studies across different populations [44,45]. In this research, the scores of the questions were not aggregated, but we focused only on the following two questions provided separately per device: "Please rate the ease of wearing and/or using the device," where participants could answer on a 1-7 scale (1=very acceptable, 7=very unacceptable), and "Would you be willing to use the device in the future, and if so, for how long?," where participants could select from "No," "Yes, less than 1 week," "Yes, 1-4 weeks," and "Yes, more than 4 weeks".

Endpoint Generation

Physical activity endpoints were derived from the GENEActiv wrist accelerometer using the vendor-supplied proprietary algorithm. This algorithm aggregates the 50 Hz triaxial raw accelerometry data into 1-minute summaries by extracting the signal vector magnitude (SVMg). Based on SVMg thresholds, the algorithm distinguishes wear from nonwear periods, and during wear periods, it classifies activity as sleep, sedentary, light, moderate, and vigorous. Visit days were excluded from the analysis, as they contained only partial recordings. In addition, only participants with at least 4 compliant days were included in the analysis. For each compliant day, the following physical activity endpoints were derived: time in sedentary activity (hours), time in nonsedentary activity (hours), time in sedentary-to-light physical activity (SLPA; hours), time in moderate-to-vigorous physical activity (MVPA; hours), mean SVMg (arbitrary units [a.u.]), 95th percentile of SVMg (a.u.), mean SVMg during the maximum 6 minutes of activity (M6min; a.u.), and mean SVMg during the maximum 60 minutes of activity (M60min; a.u.). The last two endpoints have been used in the literature to quantify the average activity during the most active 6 and 60 minutes of the day and have shown significant association with traditional measures of functional capacity in older individuals [46]. Finally, physical activity endpoints were averaged across compliant days for each participant.

The following measurements were collected using the Renpho body scale and the Tanita scale: weight (kg), muscle mass (kg), fat mass (kg), fat-free mass (kg), bone mass (kg), and water mass (kg). All body composition measurements were converted to percentages of weight. In-clinic and at-home body measurements were averaged across the three visits and at-home monitoring days per participant, respectively.

To obtain meal-related endpoints, timestamps, which were manually transcribed from each meal photo by two scientists and an independent reviewer, were associated with a meal weight. Weight entries from Gennec and the photos were then paired using their timestamps and meal names. In some cases, weight data were available only from Gennec, if participants did not take the photo correctly (eg, it was too blurry, or the weight was not photographed) or if participants did not take a photo at all. In other cases, weight data were available only from the photo if participants did not connect Gennec to the Renpho nutrition scale, they did not open the app to trigger a new meal recording, or the meal was not left long enough on the scale for the app to record the weight. When the weight was available from both sources, the average weight was computed for both pre- and postmeal entries. The meal net weight (g) was computed as the difference between the post- and premeal weights.

In the case of prepackaged meals, the meal macronutrient content was available, including energy (kcal), fat (g), sodium (g), potassium (g), carbohydrates (g), protein (g), and potassium (g). The net macronutrient content of the meal was computed by applying the percentage of consumed meal weight (ratio of meal net weight and premeal weight) to the macronutrient content of the prepackaged meal, under the assumption that participants consumed the same percentage of macronutrients in the meal. The net macronutrient content was computed only for the prepackaged meals. Meal duration was obtained as the time that elapsed between the pre- and postmeal times. The averages of net weight, energy, macronutrient content, and duration across meals were extracted per participant.

The following endpoints were computed from the Abbott Freestyle Libre Pro CGM data for each at-home monitoring day: mean (SD; mg/dL), minimum (mg/dL), maximum (mg/dL), time in range (TIR, %, defined as the percentage time within 70-180 mg/dL), time below range (TBR, %, defined as the percentage time below 70 mg/dL), and time above range (TAR, %, defined as the percentage time above 180 mg/dL). CGM endpoints were averaged across monitoring days per participant.

PROMIS Physical Function 10a scores were converted to *t*-scores (mean 50, SD 10, representing the US general population) according to standard guidelines [43]. PROMIS Physical Function 10a *t*-scores as well as appetite and fatigue PRO scores were averaged across monitoring days per participant.

Statistical Analysis

The relationship between frailty and nutritional groups was investigated via chi-square tests performed between pairs of categories (ie, FFS vs MNA-SF, FFS vs SNAQ, MNA-SF vs SNAQ), with scatter plots and Spearman's correlation.

The endpoints derived from DHTs at home were tested to assess whether they distinguished the frailty or nutritional groups. For this purpose, a linear regression model was leveraged, with the average endpoint as a dependent variable and the group (ie, nonfrail/prefrail/frail, nonrobust/robust, or normal nutrition/at risk for malnutrition), age, and sex as independent variables. Height was also added as an independent variable for models investigating differences in weight and body composition endpoints.

Model residuals were characterized in terms of normality via the Shapiro-Wilk test and homogeneity of the variance across groups via Levene's test. The presence of an overall statistically significant association between endpoints and groups was investigated via one-way ANOVA in the case of normality and

XSL•FO
RenderX

homogeneity of the residuals, Welch's ANOVA in the case of normality but nonhomogeneity of the residuals, or the Kruskal-Wallis test in the case of nonnormality of the residuals. For $P<0.1$, post hoc pairwise tests were performed to assess differences between pairs of frailty groups via least square comparisons following ANOVA or Wilcoxon tests following the Kruskal-Wallis test. The 0.1 threshold was chosen to flag digital endpoints exhibiting potential trends across groups, thereby reducing type II error. No correction for multiple comparisons was applied [47].

The association between digital endpoints with PRO scores was assessed using Spearman's correlation (ρ) to account for outliers.

Agreement between the Renpho body scale (test device) and the Tanita scale (reference device) endpoints collected during in-clinic visits was assessed using the intraclass correlation coefficient (ICC; two-way random-effects model, absolute agreement) following benchmarks reported by Cicchetti et al [48]: ICC≤0.4, poor agreement; ICC=0.4-0.59, fair agreement; ICC=0.6-0.74, good agreement; and ICC=0.75-1, excellent agreement. The mean difference (bias), limits of agreement (LoA), mean absolute difference, mean percentage error, and Pearson's correlation coefficient (R) were also computed. Scatter plots and Bland-Altman plots with 95% LoA were used to visualize agreement.

All statistical analyses were performed in R version 3.4.2 (R Foundation for Statistical Computing) using the following main packages: *car* for type III ANOVA, *BlandAltmanLeh* for Bland-Altman plots, and *psych* for the ICC.

Results

Demographics

In total, 94 older individuals (n=48, 51%, females) aged 65-96 (mean 72.98, SD 6.28) years with a BMI of 17.3-50.4 (mean 25.81, SD 4.60) kg/m^2 were recruited across GAS-1 (n=50, 53%) and GAS-2 (n=44, 47%) and were monitored with DHTs at home for 8-16 (mean 12.43, SD 1.20) days (excluding visit days). Of the 94 participants, 7 (7%) reported partial use of walking aids (eg, cane, walker, or leg braces), and 6 (6%) reported previous hip or knee replacement.

According to the MNA-SF, nutritional status was classified as "normal" for 67 (71%) participants (mean age 72.39, SD 5.57 years), of which 28 (42%) were females, and "at risk for malnutrition/malnourished" for 27 (29%) participants (mean age 74.44, SD 7.69 years), of which 20 (74%) were females. According to the SNAQ, nutritional status was classified as "normal" for 70 (74%) participants (mean age 73.58, SD 6.17 years), of which 36 (51%) were females, and "at risk for malnutrition/weight loss" for 24 (26%) participants (mean age 71.21, SD 6.39 years), of which 12 (50%) were females. Participants' characteristics are presented in Table 1, stratified by frailty phenotype. Chi-square tests showed expected significant associations between groups (FFS vs MNA-SF: $P<.001$; FFS vs SNAQ: $P<.01$; MNA-SF vs SNAQ: $P<.05$). Scatter plots with Spearman's correlation between the FFS, MNA-SF, and SNAQ are reported in Figure S1 in Multimedia Appendix 1.

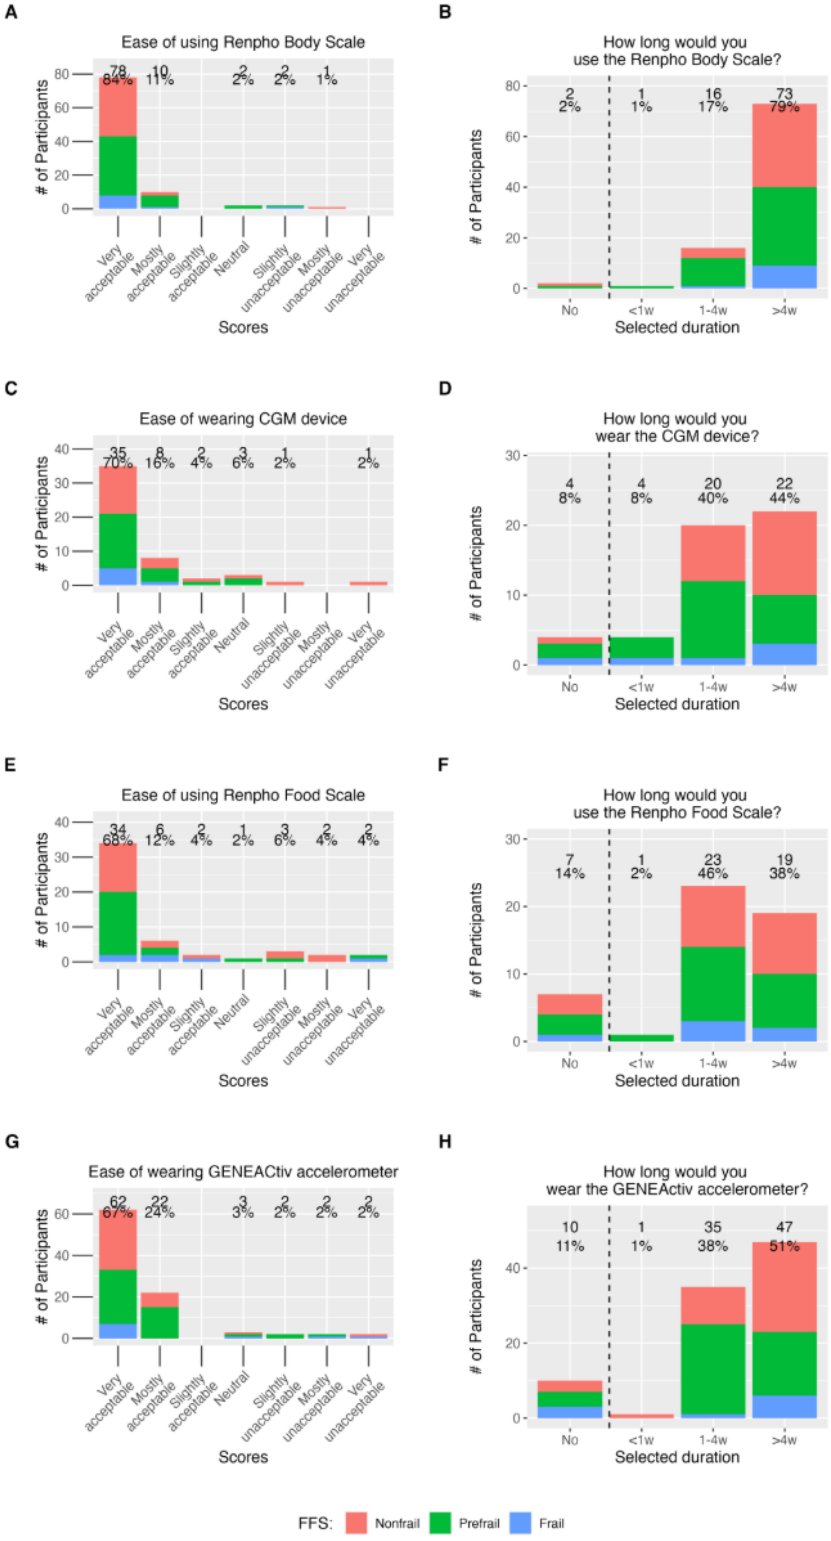
Physical Activity at Home Distinguishes Frailty and Nutritional Status and Correlates With PROs

A compliant day was defined as a day with at least 18 hours of wear time, in agreement with previous literature [49,50], resulting in a mean percentage compliance of 92.04% (SD 17.32%, range 21.00%-100.00%) across participants (Table 1). Data from 3 (3%) participants with less than 4 compliant days were excluded from the analysis, resulting in 91 (97%) compliant participants. During compliant days, participants had a mean wear time of 23.13 (SD 0.82, range 19.91-24.00) hours/day. Questionnaire responses showed that of 93 participants, 84 (91%) found the wrist accelerometer mostly to very acceptable to wear (Figure 1A), and 82 (89%) indicated that they would wear the wrist accelerometer for more than 1 week (Figure 1B).

ANOVA showed a significant effect of frailty status on all physical activity endpoints except SLPA (Table 2). Time spent in sedentary activity, nonsedentary activity, and MVPA (Figure 2A) was significantly different across frailty groups: the nonfrail group spent significantly more time in nonsedentary activity compared to both prefrail and frail groups, significantly more time in MVPA compared to both prefrail and frail groups, and significantly less time in sedentary compared to the frail group. In addition, the mean and 95th percentile of SVMg, as well as M6min and M60min (Figure 2B), were significantly different across frailty groups. The results were concordant when comparisons were performed across the two robustness groups, with the nonrobust group showing significantly higher time in sedentary activity and lower time in nonsedentary activity, MVPA, mean SVMg, 95th percentile of SVMg, M6min, and M60min, compared to the robust group.

Furthermore, a significant age effect was observed for time spent in nonsedentary activity (P<.01), MVPA (P<.01), mean SVMg (P<.05), and 95th percentile of SVMg (P<.01), while a significant effect of sex was observed for M6min (P<.001), with female participants showing a lower M6min (mean 528, SD 135 a.u.) compared to male participants (mean 679.2, SD 270 a.u.).

Physical activity endpoints related to high-intensity activity, that is, M6min and M60min (Figure 2D) were significantly different across SNAQ groups. None of the physical activity endpoints showed a significant difference across MNA-SF groups (Table 3).



Two participants did not complete the appetite and fatigue questionnaires at home, resulting in a total of 92 (98%) respondents. The question on appetite was answered at home for an average of 13.31 (SD 2.28) days per participant, with an average score of 8.02 (SD 1.87) across participants. The average appetite score differed across frailty groups ($F_{2,87}$=4.53, P=.01), robustness ($F_{1,88}$=5.24, P=.02), and nutritional (MNA-SF: $F_{1,88}$=4.76, P=.03; SNAQ: $F_{1,88}$=18.42, P<.001) groups, as illustrated in Figure S5 in Multimedia Appendix 1. M6min (ρ=0.3, P<.01) and M60min (R=0.28, P<.01) showed a significant correlation with the average appetite score.

The question on fatigue was answered at home for an average of 13.27 (SD 2.34) days per participant, with an average score of 2.95 (SD 2.09) across participants. The average fatigue score differed across frailty groups ($F_{2,87}$=10.01, P<.001), robustness ($F_{1,88}$=14.52, P<.001), and nutritional (MNA-SF: $F_{1,88}$=4.01, P<.05; SNAQ: $F_{1,88}$=6.01, P<0.5) groups, as illustrated in Figure S6 in Multimedia Appendix 1. M60min (ρ=–0.23, P<.05) showed a significant but weak correlation with the average fatigue score.

All participants completed the PROMIS Physical Function 10a questionnaire, resulting in a mean t-score of 52.28 (SD 9.01) across participants. The average t-score differed across frailty ($F_{2,89}$=12.68, P<.001), robustness ($F_{1,90}$=11.6, P<.001), and nutritional (MNA-SF: $F_{1,90}$=4.83, P<.05; SNAQ: $F_{1,90}$=20.2, P<.001) groups, as illustrated in Figure S7 in Multimedia Appendix 1. The time spent in nonsedentary activity (ρ=0.35, P<.001), the time spent in MVPA (ρ=0.42, P<.001; Figure 2E), the mean SVMg (ρ=0.32, P<.01), the 95th percentile of SVMg (ρ=0.4, P<.001), M6min (ρ=0.34, P<.01), and M60min (ρ=0.47, P<.001; Figure 2F) were significantly correlated with the PROMIS Physical Function 10a t-scores.

RenderX

Figure 1. Scores from the comfort and wearability questionnaires, stratified across frailty groups. (A, B) Renpho Body Scale, (C, D), CGM, (E, F), Renpho Food Scale, and (G, H) GENEActiv accelerometer. The color indicates the frailty phenotypes: nonfrail (red), prefrail (green), and frail (blue). Most of the participants found the devices easy to wear or use and indicated their willingness to wear or use them for at least 1 week regardless of their frailty status/score. CGM: continuous glucose monitoring; FFS: Fried Frailty Score.

Figure 2. (A, C, E) MVPA and (B, D, F) and M60min across (A, B) frailty groups, (C, D) across nutritional groups, and (E, F) against PROMIS Physical Function 10a t-scores. (A-D) Data are reported in boxplot representation: central horizontal lines represent the median, boxes mark the IQR, black lines are the whiskers, and black dots indicate outliers. H-scores, degrees of freedom, and *P* value of Kruskal-Wallis checking the association between average endpoints and groups are reported in the title. Colors indicate the frailty group (nonfrail [red], prefrail [green], and frail [blue]) or the nutritional group (normal nutrition [green] and at risk for malnutrition [purple]). Frail participants showed significantly lower MVPA and M60min, and participants at risk for malnutrition showed significantly lower M60min and a smaller MVPA median value. (E, F) Data are reported as scatter plots, where each dot represents the average across participants' daily measurements. Colors indicate the frailty group, while shapes indicate the nutritional group. Spearman's correlation and related *P* values are annotated. Significant correlation with self-reported physical function was observed for both MVPA and M60min. FFS: Fried Frailty Score; M60min: maximum 60 minutes of activity; MVPA: moderate-to-vigorous physical activity; PROMIS: Patient-Reported Outcomes Measurement Information System; SNAQ: Simplified Nutritional Appetite Questionnaire.

DHTs Can Enable Patient-Centric Clinical Trials in Older Individuals

The accuracy of the weight and body composition measurements from the Renpho Body Scale and the Tanita scale was compared during in-clinic visits. Perfect agreement (ICC=1) and correlation (R=1) were observed for weight. Mean percentage errors<1% were found for weight and water mass and <4% for muscle mass, fat mass, and fat-free mass. Interestingly, a higher error and nonhomogeneous bias were observed when considering absolute rather than percentage measurements. A comprehensive comparison between the Renpho Body Scale and the Tanita scale is reported in Multimedia Appendix 1.

Compliant days at home using the Renpho Body Scale were defined as those with at least one measurement, resulting in an average percentage compliance of 88.36% (SD 20.49%) across participants. Only 1 (1%) participant did not collect any at-home measurements (0% compliance; this participant felt unsafe using the scale without assistance), while 39 (41%) participants weighed themselves every day (100% compliance). Furthermore, 2 (2%) participants were unable to connect the body scale to the app; thus, only their weight was captured, not the body composition measures.

Questionnaire responses showed that 88 (95%) of 93 participants found the Renpho Body Scale mostly to very acceptable to use, and 89 (97%) of 92 participants indicated that they would use the body scale for more than 1 week.

ANOVA did not show any statistically significant difference across frailty, robustness, or nutritional groups for any of the Renpho Body Scale endpoints. As expected, height showed a significant effect on weight (*P*<.001). In addition, sex showed a significant effect on muscle mass (females: mean 64.96%, SD 8.37%; males: mean 72.85%, SD 4.90%; *P*<.001), fat mass (females: mean 30.92%, SD 8.87%; males: mean 23.30%, SD 5.13%; *P*<.01), water mass (females: mean 47.46%, SD 6.21%; males: mean 55.32%, SD 3.84%; *P*<.001), and fat-free mass (females: mean 69.08%, SD 8.88%; males: mean 76.70%, SD 5.13%; *P*<.01).

Muscle mass (ρ=–0.32, *P*<.01), bone mass (ρ=–0.23, *P*<.05), fat mass (ρ=0.32, *P*<.01), fat-free mass (ρ=–0.32, *P*<.01), and water mass (ρ=–0.31, *P*<.01) showed a significant but weak

XSL•FO
RenderX

correlation with self-reported fatigue. Similarly, muscle mass (ρ=0.32, P<.01), bone mass (ρ=0.21, P<0.05), fat mass (ρ=–0.32, P<.01), fat-free mass (ρ=0.32, P<.01), and water mass (ρ=0.31, P<.01) showed significant correlations with self-reported physical function.

Of 50 participants, CGM data were available for 43 (86%) participants: For 2 (4%) participants, the devices failed to connect to the reader at the last visit; 1 (2%) participant lost the device during the study; for 3 (6%) participants, the device fell off during the second day of monitoring; and for 1 (2%) participant, the device appeared damaged at the last visit (with the adhesive partially removed and the needle bent sideways).

Excluding visit days, CGM data were recorded for an average of 10.12 (SD 3.37, range 1.00-14.00) days, corresponding to an average of 84.27% (SD 26.68%, range 8.33%-100.00%) of the monitoring period. In total, 25 (50%) participants wore the CGM every day (100% compliance). During days with CGM recordings, the average wear time was 23.23 (SD 1.39, range 18.00-24.00) hours across participants.

Questionnaire responses showed that 43 (86%) of 50 participants found the CGM device mostly to very acceptable to wear, and 42 (84%) of 50 participants indicated that they would use the CGM for more than 1 week.

ANOVA did not show any statistically significant differences across frailty, robustness, or nutritional groups for any CGM endpoints. However, the frail group showed a higher TBR (~7%), and a lower TIR (~8%) compared to nonfrail and prefrail groups (Table S3 in Multimedia Appendix 1).

The minimum glucose concentration showed a significant correlation with self-reported appetite (ρ=0.32, P=.04) and self-reported fatigue (ρ=–0.31, P=.05).

Participants were considered compliant with using the Renpho Nutrition Scale only if they weighed a meal both before and after consumption. The percentage of days with at least one compliant meal entry was an average of 60.29% (SD 37.00%, range 0.00%-100.00%) across all participants. In addition, 1 (2%) participant was unable to record any meals with the nutrition scale throughout the study, while 4 (8%) participants weighed their meals only once (either before or after consumption) throughout the study. Furthermore, 5 (10%) participants were compliant every day (100% compliance), and 34 (68%) reported at least three meals on an average of 53.40% (SD 24.68%, range 6.66%-92.31%) of the monitoring days. Finally, across participants, a mean total of 25.34 (SD 23.24, range 0.00-121.00) meals were correctly entered during the study using the Renpho Nutrition Scale, resulting in 1267 total meals.

Questionnaire responses showed that 40 (80%) of 50 participants found the nutrition scale mostly to very acceptable to use, and 42 (84%) of 50 participants indicated that they would use the nutrition scale for more than 1 week.

The histograms of meal net weight, meal duration, time between consecutive daily meals, and number of daily meals are reported in Figure S8 in Multimedia Appendix 1. ANOVA showed significant differences between frailty groups only for the net sodium ($F_{2,45}$=4.4, P=.02) and net potassium ($F_{2,45}$=3.6, P=.03) content, which were lower in the frail group compared to the nonfrail (P<.05) and prefrail (P<.05) groups. However, no significant differences across robustness groups were observed for any meal endpoints (Table S3 in Multimedia Appendix 1).

Sex showed significant effects on meal net weight (females: mean 263.3, SD 79.8; males: mean 322.2, SD 72.2; P<.05) and meal net protein (females: mean 19.71, SD 6.91; males: mean 25.39, SD 5.14; P<.05). Age showed a significant effect on meal duration ($F_{1,45}$=9.79, P<.01), with older participants being associated with a longer meal duration. When grouping by SNAQ (but not MNA-SF), participants at risk for malnutrition reported a significantly lower number of daily meals ($F_{1,46}$=6.89, P<.05) and a significantly lower meal net weight ($F_{1,46}$=6.83, P<.05), as summarized in Table S4 in Multimedia Appendix 1. After adding the meal net weight as a model covariate, participants at risk for malnutrition exhibited a significantly longer meal duration ($F_{1,45}$=6.29, P<.05).

The meal net weight showed a significant correlation with self-reported appetite (ρ=0.30, P<.05) and physical function (ρ=0.48, P<.001).

Discussion

Principal Findings

We explored the use of DHTs, including wrist accelerometers, body scales, CGM, and food scales, to remotely monitor the overall well-being of older individuals at risk for frailty and malnutrition. We observed that physical activity endpoints collected at home with a wrist accelerometer and in the lab were significantly different between frailty and nutritional groups. Across all participants, a higher average daily time in SLPA than in MVPA was observed; however, frailty status had a significant effect only on MVPA, with the frail group spending significantly less time in MVPA than the nonfrail group, confirming previous findings [51,52]. A systematic review by Tolley et al [53] reported that time spent in sedentary activity is usually significantly lower in individuals who are frail compared with those who are not. However, the relationship between sedentary time and frailty status is not always consistent [54], and higher sedentary time in nonfrail compared with frail cohorts has also been reported [55]. In this work, sedentary time was significantly higher in the frail compared with the nonfrail group and in the nonrobust compared with the robust group. These findings confirm those reported in our previous study [35], where the frail group spent more time in sedentary activity and less time in MVPA and exhibited significantly a lower 95th percentile of SVMg. In this research, additional physical activity endpoints, including time spent in nonsedentary activity, mean SVMg, and mean activity during M6min and M60min, distinguished frail and nonrobust groups from nonfrail and robust groups. This difference is possibly related to the larger sample size.

A link between nutritional status and physical activity in older adults has already been hypothesized in the literature: Tamamura et al [56] showed that patients with higher MNA-SF scores at admission to rehabilitation wards had greater functional

XSL•FO
RenderX

independence at discharge, and Hsueh et al [57] observed that individuals without a healthy diet were more sedentary compared with those with a healthy diet. In this study, we showed that objectively and remotely measured mean activity during M6min and M60min are significantly lower in participants at risk for malnutrition compared with those with normal nutritional status, as assessed with the SNAQ, confirming the relationship between physical activity and nutritional status in older individuals. Notably, physical activity endpoints were not sensitive to MNA-SF groups, suggesting that the SNAQ might be preferable as an anchor metric in studies assessing minimal clinically important differences in digital endpoints.

Wrist-derived physical activity endpoints have already been associated with self-reported behaviors in older individuals [58]; here, we confirmed the relationship between physical activity endpoints and self-reported measures of appetite [59], fatigue [60], and physical function [61]. These findings suggest that digital endpoints collected in free-living settings are concordant with individuals' perceptions, while unobtrusively providing more objective and sensitive data to complement PROs, as already noted in the literature [37,62]. Indeed, a ceiling effect was observed in self-reported physical function scores but not in physical activity digital endpoints. As noted previously [63], despite the observed correlation, subjective and objective physical activity measures may differ and should potentially be used complementarily [64].

Our findings support the deployment of wrist accelerometers in clinical studies as effective, noninvasive, and highly informative tools for monitoring older adults' physical activity in free-living conditions and for obtaining insights into their frailty and nutritional status. These tools enable vulnerable populations, such as older individuals, to participate in clinical trials with fewer burdensome visits, thereby expanding access to care. In addition, tracking daily levels of physical activity can help health care professionals assess mobility, sleep, and overall well-being, in turn supporting the development and adjustment of coaching programs for older individuals [65].

Furthermore, we showed that other DHTs can be effectively deployed for older individuals to remotely monitor their weight, body composition, glucose concentration, and meal intake, thus enabling more patient-centric and data-centric clinical trials.

In this work, we showed that the Renpho Body Scale, a small and cost-effective device (~US $30 compared with ~US $7000 for the Tanita scale) that offers scalability and ease of use for both participants and health care professionals, provides accurate measures of weight and percentages of muscle mass, fat mass, fat-free mass, and water mass compared to the research-grade Tanita scale. Although these findings should be further corroborated by comparison against other highly accurate measures of body composition (eg, dual X-ray absorptiometry), they provide evidence for the feasibility of frequent monitoring of weight and body composition in older individuals. These measures can support monitoring underlying conditions, such as AoA, fluid retention, or functional decline, and may be indicative of medication effects [66]. For example, daily body composition measurements can reveal reductions in bone mass, which may indicate osteoporosis, or reductions in muscle mass, which may lead to sarcopenia [67].

Data collected in this study using a digital nutrition scale showed that participants at risk for malnutrition consumed a significantly lower number of daily meals, resulting in lower macronutrient intake, confirming previous findings [68,69]. However, as suggested by Madeira et al [68], this relationship is not absolute: eating more meals does not guarantee good nutritional status if the meals are low in nutritional value. Therefore, a digital nutrition scale represents a useful tool for comprehensive assessment of total dietary intake and nutritional quality in clinical trials. These measures are vital for establishing dietary treatment strategies, tailored to meet individuals' needs and to prevent energy and nutrient deficiencies, which are associated with increased length of hospital stay, hospital readmission, decreased survival time, and increased incidence of infection in hospitalized older patients [70,71]. Nevertheless, the lower compliance with this device suggests the need for more automated tools to track dietary behavior. For example, CGM data coupled with suitable artificial intelligence algorithms might offer a solution for automatically detecting meal intakes [72].

The importance of monitoring daily glucose fluctuations, including hypoglycemic periods and postprandial peaks, has been increasingly investigated in recent years, and correlations with various microvascular and macrovascular complications have been identified [73]. Although CGM devices are widely used in type 1 diabetes to capture dynamic glycemic profiles, the applicability in older individuals has been less extensively explored. Uotani et al [30] found that women with eating disorders exhibit higher glucose variability and a greater propensity for hypoglycemia, suggesting CGM as a valuable tool for mitigating the risk for severe morbidity and mortality in this population. Zhong et al [74] used CGM for 2 weeks in 698 healthy older individuals (median age 69.1 years), showing excellent glycemic control with median TIR, TBR, and TAR of 94.7%, 3.29%, and 0.64%, respectively. Compared to these values, we observed a higher average TBR, suggesting that older participants at risk for AoA may have poorer glycemic control and may be more susceptible to hypoglycemia.

Understanding older adults' perceptions of new technologies is crucial for deploying these technologies in clinical trials and everyday life [75,76]. Evaluating the acceptance of DHTs involves measuring both participants' self-reported usability and acceptability as well as their level of continued use. In this study, more than 80% of participants reported the devices to be mostly to very acceptable to wear/use and indicated that they would wear them for more than 1 week. These findings support the deployment of DHTs for older individuals for longer durations, for example, to assess treatment effects in interventional studies or to track physical and physiological changes over time in longitudinal studies, thereby accessing more granular data than those collected sporadically during in-clinic visits [77]. Compliance was also high: all participants were compliant for more than 90% of monitoring days with the wrist accelerometer, more than 85% with the digital body scale, and more than 60% with the digital nutrition scale. CGM data were available for 43 of 50 participants, who were compliant

XSL•FO
RenderX

for more than 80% of monitoring days. These findings support the deployment of DHTs in clinical trials involving older individuals to enhance patient- and data-centricity. Although limited data loss was observed in this study, some issues with CGM and the nutrition scale highlighted the importance of providing clear and detailed training materials to clinical sites for future studies, potentially supported by artificial intelligence [78].

Limitations

This study has several limitations. First, because it was cross-sectional, causality between digital endpoints, frailty, malnutrition, and other PROs cannot be established. In addition, the sample size across frailty groups was unbalanced, with the frail group accounting for only about 10% of the dataset and all being female. To mitigate this limitation, analyses were also performed by grouping nonfrail and prefrail groups into the nonrobust category and by including sex as a covariate in ANOVA models. Finally, because meal assessment occurred in an unsupervised environment, results may have been affected by unreported or misreported meals.

Conclusion

In conclusion, monitoring physical activity, weight, and dietary intake represents a cornerstone of effective health management in daily life. As the population ages worldwide, with the number of people aged 60 years and older expected to double by 2050 to approximately 2 billion, understanding the implications of aging becomes crucial for policymakers, health care professionals, and society. In this context, digitalized data collection represents a reliable and cost-effective approach to reducing in-person visits, while providing health care providers with rich longitudinal data on older individuals living in the community or in assisted-living facilities.

Acknowledgments

The two studies were conducted as a collaboration between Boston University and Pfizer. Boston University was the study sponsor.

Data Availability

Upon request, and subject to review, the study sponsor, Boston University, will provide data that support the findings of this study. Subject to certain criteria, conditions, and exceptions, Boston University may also provide access to the related individual deidentified participant data. Contact Boston University for more information. Further inquiries can be directed to the corresponding author.

Conflicts of Interest

NC, DJP, AM, and FIK are Pfizer employees and might own Pfizer stocks. GK was a paid contractor to Pfizer in connection with the development of this paper. MW, NSK, HZ, IM, ZH, MK, CD, MS, DC and KCT have no conflicts of interest to declare.

Abstract

Background: Immersive virtual reality (VR) is increasingly used for embodied training, but its practical value for older adults depends on whether the experiential benefits can be achieved without unacceptable discomfort or overstated claims about motor learning.

Objective: This randomized study compared head-mounted immersive VR with standardized, content-matched 2D video instruction for Tai Chi movement-encoding in community-dwelling older adults.

Methods: A total of 106 older adults were randomized to immersive VR (n=56) or video instruction (n=50). The primary analysis included 92 participants with complete age, pretest, and posttest data (VR: n=45; Video: n=47). The primary outcome was a 5-item movement-encoding knowledge score (range 0‐20), analyzed using analysis of covariance, with posttest score as the dependent variable and group, pretest score, and age as predictors. Secondary outcomes were intrinsic motivation, game experience, and learning engagement; safety, tolerability, and feasibility were assessed using the Intrinsic Motivation Inventory, Game Experience Questionnaire, Utrecht Work Engagement Scale–Short Form, participant flow, and Virtual Reality Sickness Questionnaire. VR system telemetry was analyzed descriptively as an exploratory process outcome.

Results: Adjusted posttest movement-encoding performance did not differ between VR and video instruction (adjusted difference −0.27, 95% CI −2.25 to 1.72; P=.79; partial η^2=0.001). The Game Experience Questionnaire results favored VR for competence (Video: mean 3.36, SD 1.21; VR: mean 4.15, SD 0.92; q=0.009), flow (Video: mean 3.77, SD 1.26; VR: mean 4.46, SD 0.76; q=0.014), and lower tension (Video: mean 1.76, SD 1.04; VR: mean 1.27, SD 0.63; q=0.037), whereas challenge did not remain significant after false discovery rate correction (q=0.073). In the VR Group, recognition accuracy was associated with posttest movement-encoding score (n=44; r=0.317, P=.04), but pose accuracy was not (n=44; r=0.129, P=.41). The Virtual Reality Sickness Questionnaire scores were low among valid VR participants (total score mean 3.77, SD 11.12), and 36 out of 46 (78%) participants reported zero symptoms.

Conclusions: With a strong active control, immersive VR did not produce higher short-term Tai Chi movement-encoding performance than video instruction. Among participants who completed the VR session, the immediate game-experience profile was more favorable. These findings indicate that VR may offer experiential benefits, while also highlighting the need to manage cybersickness and technical exclusions and to distinguish movement knowledge from actual motor execution.

Introduction

Rationale for the Study

As societies age, maintaining functional independence has become a central public health priority, particularly given the heightened consequences of balance failure and mobility decline in later life [1-3]. Tai Chi is frequently recommended for older adults because it combines controlled postural transitions with sustained attention to movement elements and goal-directed practice that can be adapted to heterogeneous functional levels [4-6]. Unlike purely verbal or screen-based cognitive tasks, Tai Chi learning requires embodied visuomotor mapping and multisensory integration, making it a suitable test bed for studying how immersive virtual reality (VR) shapes action-related memory encoding in later life [7-9]. Yet, the real-world dissemination of Tai Chi in community contexts faces a persistent accessibility paradox: the individuals who could benefit most from structured practice often have the least reliable access to safe, repeatable instruction [10-12]. Shortages of qualified instructors, geographic and scheduling constraints, and the practical challenges of maintaining consistent supervision can all limit participation [11,13,14]. Additionally, complex movement learning may carry a psychological barrier for novice learners, as uncertainty about "doing it correctly" can discourage sustained engagement even when motivation to improve health is high [11,13,15].

Immersive VR has been proposed as a scalable approach to deliver standardized movement learning experiences under controlled conditions, offering a headset-based practice space that can reduce external distraction and support repeated exposure to the same instructional sequence [10,16,17]. However, the evidence base for VR and related immersive training and learning, especially for de novo acquisition of complex movement sequences, remains fragmented and often inconsistent when compared with strong active controls [18-20]. Recent randomized studies and reviews likewise suggest that outcomes depend on training dose, adaptive design, comparator strength, and the distinction between device-recorded performance and transferable motor learning [21-24]. A key methodological limitation is that many studies rely on passive or no-treatment controls, making it difficult to isolate the effect of immersion from instructional content and practice structure. This concern echoes longstanding debates in media-comparison research: learning gains are often driven by instructional design and practice opportunities rather than the delivery medium per se [25,26]. For older adults, these issues are further complicated by immersion-specific feasibility and safety constraints, including VR discomfort and symptoms that may affect adherence and threaten generalizability if not transparently measured and reported [24,27-30].

Beyond these methodological challenges, 2 conceptual gaps remain underaddressed. First, immersive presentation is often implicitly treated as equivalent to improved execution [26,31], yet complex skill learning can be constrained by a cognitive-motor translation bottleneck: forming a representation of "what to do" does not necessarily ensure accurate embodied reproduction of "how to do it" [32]. Movement-encoding knowledge refers to the learner's immediate cognitive representation, recall, and recognition of essential movement elements and sequence-relevant cues. Such encoding is a necessary early step in learning a novel movement sequence and can be assessed comparably across VR and video conditions without treating device-specific tracking metrics as equivalent to motor skill. This distinction is especially salient for Tai Chi, where successful learning requires not only recognizing key movement elements but also coordinating posture, timing, and spatial control. Second, the mechanisms through which VR may confer value are frequently reduced to broad notions of enjoyment or novelty [33,34], while state-level conditions that shape practice quality, such as perceived competence, pressure or tension, and affective experience during learning [15], are less systematically integrated into the evidence chain. We refer to these motivational and experiential states collectively as human factors outcomes. The enclosed nature of a head-mounted display may plausibly create a more private practice context by limiting external social cues, potentially reducing pressure and negative affect while supporting engagement [17,31,35]; however, these claims require disciplined testing alongside learning outcomes, rather than being inferred from immersion alone. At the same time, feasibility depends on clearly defined safety and tolerability boundaries because immersion-related symptoms can emerge even in well-controlled settings [29].

Research Questions and Hypotheses

Guided by the identified gaps in older-adult immersive motor learning, we examined whether the more enclosed practice context created by a head-mounted display was associated with lower pressure or tension and more favorable competence-related and flow-related states. We posed the following research questions (RQs):

1. RQ1 (movement-encoding performance): When the instructional content is matched, does immersive VR produce higher posttest Tai Chi movement-encoding knowledge performance than standardized 2D video instruction after controlling for pretest score and age?
2. RQ2 (human factors outcomes): Does immersive VR systematically reshape older adults' motivational and experiential states during training (eg, interest or enjoyment, perceived competence, pressure or tension, immersion, flow, and engagement) relative to standardized video instruction?
3. RQ3 (safety, tolerability, and feasibility): In real-world community deployment, what safety, tolerability, and feasibility profile does immersive VR show, including VR discomfort or symptoms, discontinuation or exclusion due to discomfort or technical failure, and the proportion of participants reporting zero Virtual Reality Sickness Questionnaire (VRSQ) symptoms?

XSL•FO
RenderX

Based on these questions, we specified the following hypotheses:

1. H1 (movement-encoding performance): Compared with the Video Group, the VR Group will show higher adjusted posttest movement-encoding knowledge scores when controlling for pretest performance and age.
2. H2 (human factors benefit): Compared with the Video Group, the VR Group will report a more favorable motivational and experiential profile, reflected in higher perceived competence and flow or immersion and lower pressure or tension.

Because safety, tolerability, and feasibility were evaluated descriptively, RQ3 was exploratory, and no directional hypothesis was specified.

In addition, for the VR Group, system logs (recognition accuracy, pose accuracy, and movement distance) were used to characterize performance descriptively during task execution, providing process-level signals to complement self-reports and learning outcomes.

Methods

Participants

A total of 106 community-dwelling older adults were recruited and enrolled between November and December 2025. Eligibility criteria were age ≥60 years, a native Chinese language background, and no self-reported major physical or mental disorders that could materially affect task participation or outcome assessment. The sample size was determined based on feasibility considerations and prior community-based studies with comparable designs. Participants were randomly assigned to either the VR Group (n=56) or the Video Group (n=50). Randomization was not stratified by age or prior Tai Chi experience; the observed age imbalance was, therefore, handled analytically by including age as a covariate and by conducting an exploratory Group × Age sensitivity analysis. Following quality control, 95 participants were retained as valid baseline cases for demographic and background comparisons (VR: n=46; Video: n=49).

Experimental Design

We used a 2-arm pretest/posttest control-group design. The independent variable was learning modality (immersive VR learning vs 2D video-based learning). Sessions were conducted in quiet, spacious indoor settings coordinated by local community and village activity rooms. Before each session, the research team confirmed that participants had sufficient, unobstructed space for safe movement, and on-site supervision was provided throughout.

Randomization and Allocation

The study leader generated an approximately 1:1 computer-based randomization sequence before study initiation. Allocation was implemented after eligibility screening, and recruitment and on-site coordination staff followed the prespecified allocation list for scheduling and documentation. The sequence was not stratified by age or prior Tai Chi experience. Participants completed the learning tasks under their assigned condition unless they withdrew or were excluded based on predefined invalid-sample criteria (eg, VR-related discomfort, technical failure, no usable data, or incomplete participation). Study-level exclusions were applied according to feasibility and data-quality criteria before the final analytic datasets were constructed. Participant flow, invalid cases, and exclusions from the primary analysis are reported in the *Results* section.

Apparatus and Materials

The VR intervention was delivered using Meta Quest 3 and Meta Quest 3S head-mounted displays (Meta Platforms, Inc). Both models use the Snapdragon XR2 Gen 2 platform (Qualcomm Technologies, Inc) and provide comparable 6 df inside-out tracking with touch plus controllers, ensuring consistent tracking fidelity and interaction across devices. The Video Group learned the same content via standard 2D instructional videos presented on a conventional display.

Procedure

All participants completed a pretest, the assigned learning session, and a posttest within the same study workflow. The learning content comprised 5 core Tai Chi forms delivered in a standardized order and format across conditions. After the learning session, participants completed postintervention questionnaires assessing intrinsic motivation, game-related experience, and engagement. For VR participants, the system additionally recorded behavioral performance indices during task execution (eg, recognition accuracy, pose accuracy, and movement distance) for descriptive reporting.

Training sessions were supervised on-site. Participants were instructed to stop immediately if they experienced dizziness, nausea, discomfort, or instability. Short breaks were allowed upon request, and the session was terminated if symptoms persisted. Any adverse events (eg, falls, near-falls, musculoskeletal pain, or persistent cybersickness symptoms) and reasons for discontinuation were documented by the staff. These procedures were implemented to minimize physical risks during standing practice among older adults and to ensure that cybersickness and balance-related safety were treated as part of real-world feasibility.

Primary Outcome: Movement-Encoding Knowledge

The primary outcome was short-term movement-encoding knowledge, defined as immediate encoding, recall, and recognition of essential movement elements and sequence-relevant cues. It was assessed using a 5-item scoring rubric developed for the present study and guided by motor-learning frameworks [8,32]. The measure was administered before and after the learning session. It should be interpreted as a cognitive movement-representation outcome, not as a direct assessment of full Tai Chi motor execution, movement quality, or long-term skill acquisition [8,32]. Each item corresponded to one Tai Chi form and was scored from 0 to 4 using a predefined rubric (total range 0 - 20; higher scores indicate more complete encoding and recall of movement elements). Total scores were computed only when all 5 items contained valid responses; otherwise, the total score was treated as missing for the primary analysis [36]. The 5-item scoring components are provided in Multimedia Appendix 1. Diagnostic reliability was acceptable for this rubric-based score (Cronbach

XSL•FO
RenderX

α: pretest=0.910, posttest=0.725; McDonald's omega total: pretest=0.914, posttest=0.743), although these coefficients should be interpreted cautiously because the measure was designed as a scoring rubric rather than a fully validated psychometric scale.

Secondary Outcome: Intrinsic Motivation

Intrinsic motivation refers to participants' immediate interest or enjoyment, perceived competence, and pressure or tension during the learning session. It was measured with 9 items from the Intrinsic Motivation Inventory (IMI) using a 1 - 7 response scale: interest/enjoyment (5 items, including 1 reverse-scored item), perceived competence (2 items), and pressure/tension (2 items, including 1 reverse-scored item). Subscale scores were calculated as item means; higher scores indicate more of the named construct. Prior confirmatory work supports the IMI subscales' factorial validity and internal consistency [37].

Secondary Outcome: Game Experience

Game experience refers to participants' immediate cognitive and affective experience of the learning environment. It was measured with the 14-item Game Experience Questionnaire (GEQ) core module using a 1 to 5 response scale. Seven 2-item subscales were calculated as the item means: competence, immersion, flow, tension, challenge, negative affect, and positive affect; higher scores indicate more of the named experience. Item allocation and scoring followed the GEQ manual [38]. Independent validation has raised concerns about the stability of the original 7-factor structure [39]; in the current sample, Cronbach α values for the seven 2-item subscales ranged from 0.462 to 0.728. GEQ subscale findings were therefore interpreted cautiously and as immediate experience indicators rather than definitive latent-trait measures.

Secondary Outcome: Learning Engagement

Learning engagement refers to the vigor, dedication, and absorption that participants reported during the learning activity. It was measured with the 9-item Utrecht Work Engagement Scale–Short Form (UWES-S) using a 1 to 7 response scale. Vigor, dedication, and absorption scores were calculated as the means of 3 items each, and total engagement as the mean of all 9 items; higher scores indicate stronger engagement. Cross-national validation supports the scale's 3-factor structure and internal consistency [40].

Safety, Tolerability, and Feasibility

Safety and tolerability refer to VR-related symptoms and the ability to complete the session without clinically relevant discomfort or instability. VR symptoms were measured in the VR Group with the 9-item VRSQ (item scores of 0-3). Oculomotor and disorientation scores were normalized to 0 to 100 and averaged to obtain a total score; higher scores indicate more severe symptoms. We also reported the absolute number and proportion with zero symptoms. The VRSQ was developed with evidence of internal consistency and convergent validity for VR-specific symptoms [41]. Feasibility was defined descriptively through participant flow and the number and reasons for discontinuation or exclusion, including discomfort, technical failure/no usable data, and incomplete participation. It was not treated as a separate psychometric construct.

Exploratory VR Behavioral Performance

VR behavioral performance refers to device-recorded process indicators available only in the VR Group. Recognition accuracy was the percentage of correct responses across 5 recognition items; pose accuracy was the percentage of correctly hit pose targets (15 total); and motion distance was the summed movement distance of the head and both hands in meters. These telemetry variables were summarized descriptively and explored using correlations; they were not designated primary or secondary learning outcomes.

Data Quality Control and Analytic Samples

Participant flow and exclusions followed a 2-layer rule consistent with CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth; Checklist 1) reporting guidance [42]. First, study-level invalid cases were removed based on predefined criteria (VR: n=10; Video: n=1), including motion sickness/discomfort, technical failure/no usable data, and incomplete participation/withdrawal, resulting in 95 valid baseline participants. Second, for the primary learning-outcome analysis, participants were included only if age, pretest score, and posttest score were all available, yielding the primary analytic sample of 92 (VR: n=45; Video: n=47). Missingness was limited: in the valid baseline sample, the Video Group had 2 out of 49 participants missing posttest scores, whereas the VR Group had 1 out of 46 missing pretest data and 1 out of 46 missing posttest data. All analyses used complete-case data for the variables involved.

Statistical Analysis

All analyses were conducted in R software (v4.6.0; R Foundation for Statistical Computing). Descriptive statistics are reported as mean (SD) for continuous variables and n (%) for categorical variables. Baseline group differences were examined using independent-samples 2-tailed Welch *t* tests (continuous variables) and Fisher exact tests (categorical variables). The primary intervention effect on posttest performance was evaluated using analysis of covariance (ANCOVA) with posttest score as the dependent variable, group as the fixed factor, and pretest score and age as covariates; adjusted group differences are reported with 95% CIs and partial η^2 [43,44]. For user-experience outcomes, group differences were examined using independent-samples 2-tailed Welch *t* tests with false discovery rate (FDR) adjustment applied across self-report outcomes [45,46]; Cohen *d* values were computed as VR minus Video. Given the baseline age imbalance, we additionally conducted age-adjusted linear models for key self-report outcomes and an exploratory Group × Age model for the primary outcome. Missing data were handled using complete-case analysis for the variables involved; a conservative sensitivity check implemented under the pretest-complete rule did not alter the primary conclusion. VR telemetry correlations with movement-encoding scores and selected self-report measures were examined descriptively using Pearson correlations.

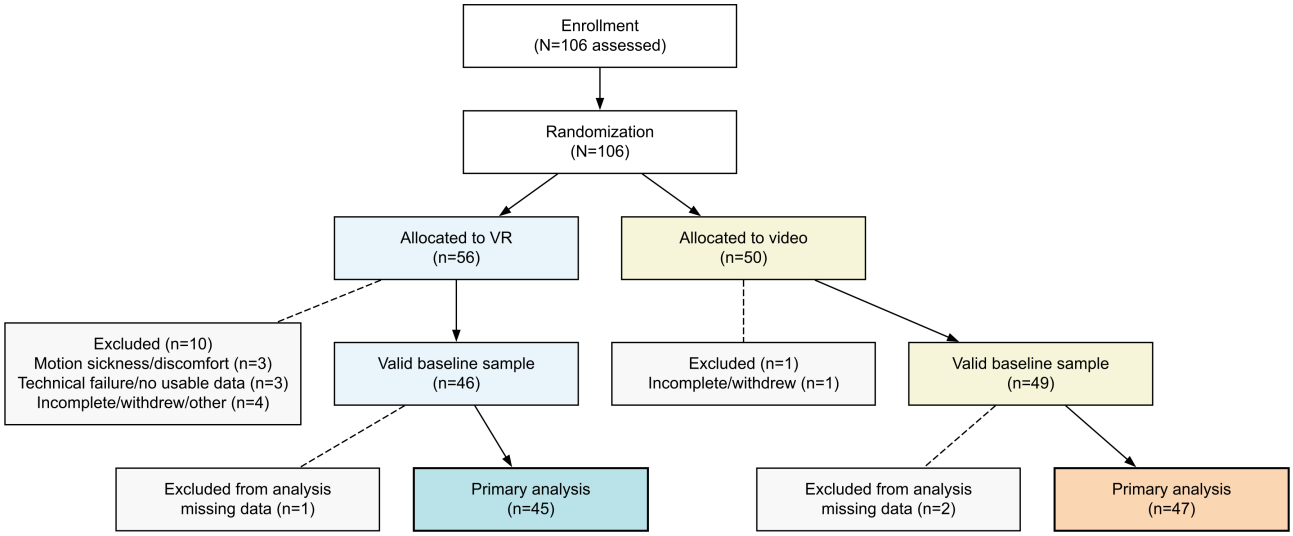
RenderX

Ethical Considerations

The study protocol was reviewed and approved by the Research Office of Xi'an Translation University on October 16, 2025. The reviewing body did not issue a case or application number. All participants provided written informed consent before participation. Participants were informed of the study procedures and potential risks, including possible VR-related discomfort, such as dizziness or eye strain, and could rest, discontinue a session, or withdraw at any time without penalty. Study data were deidentified for analysis and reporting. Participants received a small commemorative gift valued at approximately RMB $40 to $50 (RMB $1=US $0.14 as of December 8, 2025) for each study visit.

Trial Registration

This report presents first-session findings from a larger pilot randomized trial that was retrospectively registered with the International Traditional Medicine Clinical Trial Registry (registration number ITMCTR2026001760). The registry application was first submitted on April 1, 2026, after participant recruitment had commenced. The registry record includes additional follow-up assessments that are outside the scope of the present report.



Results

Participant Flow and Baseline Characteristics

As shown in Figure 1, a total of 106 older adults were assessed and randomized (VR: n=56; Video: n=50). Based on predefined invalid-sample criteria, 10 participants in the VR arm were excluded from the study (motion sickness/discomfort, n=3; technical failure/no usable data, n=3; incomplete, withdrew, or other, n=4), and 1 participant in the video arm was excluded (incomplete/withdrew, n=1), yielding 95 valid participants for baseline characterization (VR: n=46; Video: n=49), as shown in Table 1 (the 2 groups did not differ significantly in sex, education, or prior Tai Chi experience, but the Video Group was older on average). For the primary movement-encoding analysis, an additional 1 VR participant and 2 Video participants were excluded under the complete-case rule for age, pretest score, and posttest score, resulting in a final analytic sample of 92 participants (VR: n=45; Video: n=47), which was used for the ANCOVA reported in Table 2.

As shown in Table 1, baseline characteristics were summarized for the valid sample (N=95, Video Group n=49, VR Group n=46). Participants were older adults (overall mean age of 68.67, SD 7.55 y). The Video Group was older (mean 70.69, SD 7.43) than the VR Group (mean 66.52, SD 7.15 y), and this difference was statistically significant (*P*=.006). Sex distribution did not differ between groups (*P*=.16; overall: male 24/95, 25% and female 71/95, 75%). Educational attainment was also comparable across groups (*P*=.41), with the largest categories being primary school or below (31/95, 33%) and junior high school (28/95, 29%). Prior Tai Chi experience was similarly balanced (*P*=.77), with most participants reporting no prior exposure (72/95, 76%).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram for the randomized comparison of immersive virtual reality (VR) and video-based Tai Chi movement-encoding instruction among community-dwelling older adults, November to December 2025. A total of 106 participants were assessed and randomized (VR Group: n=56; Video Group: n=50). Study-level exclusions were based on prespecified invalid-sample criteria (VR: n=10; Video: n=1), including motion sickness or discomfort (VR: n=3), technical failure or no usable data (VR: n=3), and incomplete participation, withdrawal or other (VR: n=4; Video: n=1). Valid participants contributing to baseline characteristics are reported in Table 1 (VR: n=46; Video: n=49). Primary outcome analyses used the complete-case primary sample (Table 2; VR: n=45; Video: n=47).

Table . Baseline characteristics of community-dwelling older adults randomized to immersive VR[a] or video-based Tai Chi movement-encoding instruction, November to December 2025.[b]

Characteristic	Overall (N=95)	Video Group (n=49)	VR Group (n=46)	*P* value
Age (y), mean (SD)	68.67 (7.55)	70.69 (7.43)	66.52 (7.15)	.006
Sex, n (%)				.16
Male	24 (25)	9 (18)	15 (33)	
Female	71 (75)	40 (82)	31 (67)	
Education, n (%)				.41
Bachelor's degree or above	4 (4)	2 (4)	2 (4)	
Middle school	28 (29)	13 (27)	15 (33)	
Junior college	6 (6)	1 (2.0)	5 (11)	
High school or vocational school	26 (27)	15 (31)	11 (24)	
Primary school or below	31 (33)	18 (37)	13 (28)	
Prior Tai Chi experience, n (%)				.77
Never	72 (76)	37 (76)	35 (76)	
Practice often	5 (5)	2 (4)	3 (7)	
Occasionally watched	9 (10)	6 (12)	3 (7)	
Practiced a little	9 (10)	4 (8)	5 (11)	

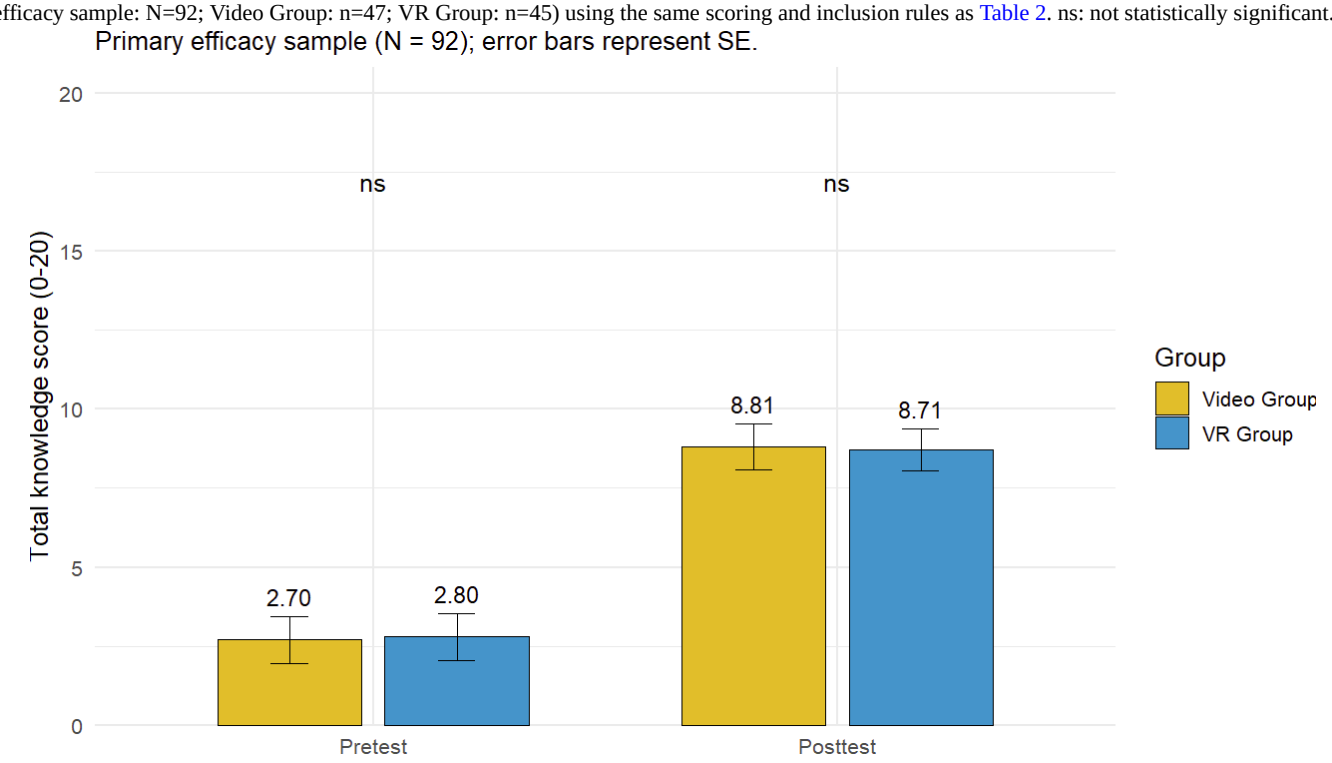
[a]VR: virtual reality.

[b]Values are mean (SD) for continuous variables and n (%) for categorical variables. Group differences were tested using independent-samples 2-tailed Welch *t* tests for age and Fisher's exact tests for categorical variables. Missing data were not included in the summaries.

Table . Pretest-posttest Tai Chi movement-encoding knowledge scores and adjusted intervention effect in community-dwelling older adults randomized to immersive VR[a] or video instruction, November to December 2025.[b]

Outcome	Video Group (n=47), mean (SD)	VR Group (n=45), mean (SD)
Pretest score (range 0‐20)	2.70 (5.09)	2.80 (4.98)
Posttest score (range 0‐20)	8.81 (4.97)	8.71 (4.49)
Movement-encoding gain	6.11 (5.88)	5.91 (6.19)

[a]VR: virtual reality.



[b]The adjusted mean difference between the VR and Video Groups was −0.269 (95% CI −2.25 to 1.72; *P*=.79), based on an analysis of covariance model with posttest score as the dependent variable, group as the fixed factor, and pretest score and age as covariates (primary analysis sample, N=92). Participants were included in the primary analysis only if age and all 5 pretest and posttest items were complete.

Primary Outcome: Movement-Encoding Knowledge

As shown in Figure 2, total movement-encoding knowledge scores (0‐20) increased from pretest to posttest in both groups within the primary analysis sample (N=92), consistent with the descriptive results summarized in Table 2. The plotted means (SE) indicate comparable patterns of improvement across the Video Group (n=47) and the VR Group (n=45) under the same scoring rule and sample definition used for the main inferential model.

XSL•FO
RenderX

Figure 2. Pretest and posttest Tai Chi movement-encoding knowledge scores among community-dwelling older adults randomized to immersive virtual reality (VR) or video instruction, November to December 2025. Scores represent the sum of 5 movement-encoding knowledge items (each scored 0 to 4), yielding a total score range of 0 to 20. Bars show the mean; error bars represent the SE. Results are based on the primary analysis sample (primary efficacy sample: N=92; Video Group: n=47; VR Group: n=45) using the same scoring and inclusion rules as Table 2. ns: not statistically significant.

As shown in Table 2, the primary analysis sample included 92 participants (Video Group n=47, VR Group n=45) with complete pretest, posttest, and age data. Descriptively, pretest movement-encoding scores were comparable between groups (Video: mean 2.70, SD 5.09; VR: mean 2.80, SD 4.98), as were posttest scores (Video: mean 8.81, SD 4.97; VR: mean 8.71, SD 4.49) and movement-encoding gain (Video: mean 6.11, SD 5.88; VR: mean 5.91, SD 6.19). In the ANCOVA model controlling for pretest score and age, the adjusted intervention effect (VR vs Video) on posttest performance was not significant (adjusted difference −0.269, 95% CI –2.25 to 1.72; P=.79; partial η^2=0.001).

Secondary Outcome: Intrinsic Motivation

As shown in Table 3, intrinsic motivation outcomes were compared between the Video Group (n=47) and the VR Group (n=46) across 3 subscales. Mean scores were similar for interest or enjoyment (Video: mean 5.23, SD 1.33; VR: mean 5.53, SD 1.10), perceived competence (Video: mean 5.47, SD 1.87; VR: mean 5.86, SD 1.27), and pressure/tension (Video: mean 2.27, SD 1.36; VR: mean 2.39, SD 1.65). None of the between-group differences reached statistical significance, and all findings remained nonsignificant after FDR correction (q=0.376, q=0.376, and q=0.879, respectively).

Table . Intrinsic motivation after a single Tai Chi movement-encoding session in community-dwelling older adults randomized to immersive VR[a] or video instruction, November to December 2025.[b]

IMI[c] subscales (range 1-7)	Video Group (n=47), mean (SD)	VR Group (n=46), mean (SD)	*P* value	*q* value
Interest or enjoyment	5.23 (1.33)	5.53 (1.10)	.24	0.376
Perceived competence	5.47 (1.87)	5.86 (1.27)	.24	0.376
Pressure or tension	2.27 (1.36)	2.39 (1.65)	.69	0.879

[a]VR: virtual reality.

[b]Between-group differences were tested using independent-samples 2-tailed Welch *t* tests. False discovery rate adjustment was applied across the self-report outcome set to obtain *q* values.

[c]IMI: Intrinsic Motivation Inventory.

Secondary Outcome: Game Experience

As shown in Figure 3, GEQ ratings showed the clearest experiential separation between groups. The figure displays the GEQ dimensions most relevant to the revised interpretation: competence, flow, tension, and challenge. FDR-adjusted q values are shown for visualization. VR participants reported higher competence and flow and lower tension after FDR correction, whereas the lower challenge rating in the VR Group was significant before correction but did not remain significant after FDR adjustment.

XSL•FO
RenderX

Figure 3. Game experience after a single Tai Chi movement-encoding session in community-dwelling older adults randomized to immersive virtual reality (VR) or video instruction, November to December 2025. Ratings are shown for Game Experience Questionnaire (GEQ) competence, flow, tension, and challenge. Box plots display the distribution of participant responses, with jittered points indicating individual observations. False discovery rate–adjusted *q* values are shown for the plotted GEQ subscales; inferential interpretation should follow the *q* values reported in Table 4.

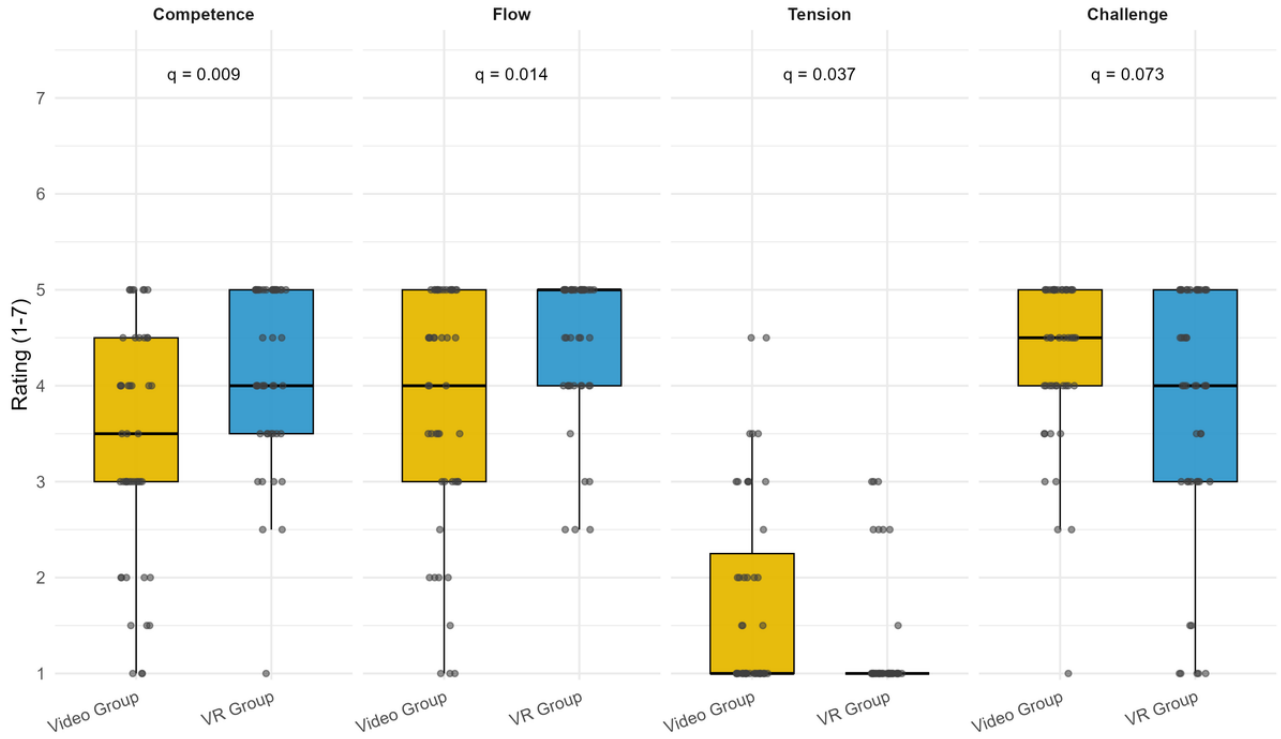


Table . Game experience after a single Tai Chi movement-encoding session in community-dwelling older adults randomized to immersive VR[a] or video instruction, November to December 2025.[b]

GEQ[c] dimensions (range 1-5)	Video Group (n=47), mean (SD)	VR Group (n=46), mean (SD)	*P* value	*q* value
Competence	3.36 (1.21)	4.15 (0.92)	<.001	0.009
Immersion	4.10 (0.95)	4.37 (0.77)	.13	0.302
Flow	3.77 (1.26)	4.46 (0.76)	.002	0.014
Tension	1.76 (1.04)	1.27 (0.63)	.008	0.037
Challenge	4.29 (0.86)	3.74 (1.33)	.02	0.073
Negative affect	1.83 (1.04)	1.83 (1.08)	.99	0.987
Positive affect	4.24 (0.87)	4.49 (0.77)	.16	0.310

[a]VR: virtual reality.

[b]Between-group differences were tested using independent-samples 2-tailed Welch *t* tests. False discovery rate adjustment was applied across the self-report outcome set to obtain *q* values.

[c]GEQ: Game Experience Questionnaire.

As shown in Table 4, game experience (GEQ; 1 - 5) differed on several dimensions between the Video Group (n=47) and the VR Group (n=46). The VR Group reported higher competence (Video: mean 3.36, SD 1.21; VR: mean 4.15, SD 0.92; *P*<.001, *q*=0.009; Cohen *d*=0.733) and higher flow (Video: mean 3.77, SD 1.26; VR: mean 4.46, SD 0.76; *P*=.002, *q*=0.014; Cohen *d*=0.661) after FDR correction. The VR Group also reported lower tension (Video: mean 1.76, SD 1.04; VR: mean 1.27, SD 0.63; *P*=.008, *q*=0.037; Cohen *d*=−0.562). Challenge was lower in the VR Group before correction (Video: mean 4.29, SD 0.86; VR: mean 3.74, SD 1.33; *P*=.02; Cohen *d*=−0.491), but this comparison did not remain significant after FDR adjustment (*q*=0.073). No significant between-group differences were observed for immersion, negative affect, or positive affect after correction.

Secondary Outcome: Learning Engagement

As shown in Table 5, learning engagement (UWES-S; 1 - 7) was broadly comparable between the Video Group (n=47) and the VR Group (n=46). Total engagement did not differ significantly (Video: mean 5.48, SD 1.49; VR: mean 5.70, SD 1.43; *q*=0.669), nor did the vigor (Video: mean 5.68, SD 1.43;

XSL•FO
RenderX

VR: mean 5.65, SD 1.67; q=0.987) or dedication subscales (Video: mean 5.50, SD 1.54; VR: mean 5.55, SD 1.57; q=0.987). Absorption showed a modest, nonsignificant trend favoring the VR Group (Video: mean 5.26, SD 1.85; VR: mean 5.89, SD 1.42; P=.07), which remained nonsignificant after FDR adjustment (q=0.192).

Table . Learning engagement after a single Tai Chi movement-encoding session in community-dwelling older adults randomized to immersive VR[a] or video instruction, November to December 2025.[b]

UWES-S[c] dimensions (range 1-7)	Video Group (n=47), mean (SD)	VR Group (n=46), mean (SD)	*P* value	*q* value
Total engagement	5.48 (1.49)	5.70 (1.43)	.48	0.669
Vigor	5.68 (1.43)	5.65 (1.67)	.93	0.987
Dedication	5.50 (1.54)	5.55 (1.57)	.89	0.987
Absorption	5.26 (1.85)	5.89 (1.42)	.07	0.192

[a]VR: virtual reality.

[b]Between-group differences were tested using independent-samples 2-tailed Welch t tests. False discovery rate adjustment was applied across the self-report outcome set to obtain q values.

[c]UWES-S: Utrecht Work Engagement Scale–Short Form.

Exploratory VR Behavioral Performance

As shown in Table 6, the VR Group's recognition accuracy averaged 75.22% (SD 31.04%), pose accuracy averaged 41.16% (SD 25.15%), and total motion distance was averaged 245.87 (SD 80.23) meters. Among participants with complete paired data (n=44), recognition accuracy was positively associated with posttest movement-encoding knowledge (r=0.317, P=.04), whereas pose accuracy was not (r=0.129, P=.41). These device-recorded indicators are exploratory process measures and should not be interpreted as direct tests of Tai Chi motor execution.

Table . Exploratory device-recorded behavioral performance during immersive virtual reality Tai Chi movement-encoding instruction among community-dwelling older adults, November to December 2025.[a]

Metric	Mean (SD)
Recognition accuracy (%)	75.22 (31.04)
Pose accuracy (%)	41.16 (25.15)
Motion distance (m)	245.87 (80.23)

[a]Recognition accuracy is the percentage of correct responses across 5 recognition items. Pose accuracy is the percentage of correctly hit pose targets (15 total). Motion distance is the sum of movement distances across the head and both hands (m). Correlations with posttest movement-encoding knowledge used 44 complete paired observations.

Safety, Tolerability, and Feasibility

Safety and tolerability outcomes are shown in Table 7. Among VR participants with valid data (n=46), the mean VRSQ total score was 3.77 (SD 11.12) on a 0 to 100 scale; oculomotor and disorientation scores were 2.90 (SD 9.50) and 4.64 (SD 13.25), respectively. A total of 36 out of 46 (78%) participants reported zero symptoms. Among participants with complete paired data (n=45), VRSQ total scores were positively associated with GEQ tension (r=.458, P=.002). Feasibility was reflected in participant flow: of 56 participants assigned to VR, 46 contributed valid baseline data; study-level exclusions included motion sickness or discomfort (n=3), technical failure or no usable data (n=3), and incomplete participation, withdrawal, or other reasons (n=4).

Table . Safety, tolerability, and feasibility of a single immersive virtual reality Tai Chi movement-encoding session among community-dwelling older adults, November to December 2025.[a]

Metric	Values
VRSQ[b] total (range 0 - 100), mean (SD)	3.77 (11.12)
Oculomotor	2.90 (9.50)
Disorientation	4.64 (13.25)
Zero symptom rate, n/N (%)	36/46 (78)

[a]Virtual Reality Sickness Questionnaire (VRSQ) total and subscale scores are scaled from 0 to 100, with higher values indicating more severe symptoms. The zero symptom rate is the absolute number and percentage of virtual reality participants with a total VRSQ symptom sum of 0. The correlation between VRSQ total scores and Game Experience Questionnaire (GEQ) tension scores was based on 45 complete paired observations. Feasibility exclusions are reported in Figure 1 because they occurred before the construction of the valid baseline sample.

[b]VRSQ: Virtual Reality Sickness Questionnaire.

Discussion

Key Findings and Contribution

This randomized study found no evidence that immersive VR improved short-term Tai Chi movement-encoding knowledge relative to content-matched video instruction. After accounting for baseline knowledge and the between-group age difference, posttest performance did not differ between conditions. Among participants who completed the VR session, however, game-related competence and flow were higher, and tension was lower. In this setting, the main observed difference between the delivery modes was, therefore, experiential rather than cognitive performance.

Movement-Encoding Knowledge

Richer sensory presentation does not necessarily produce better learning [19,25,47]. In this study, scores increased descriptively from pretest to posttest in both groups, but VR did not yield higher adjusted posttest performance. This result is consistent with the view that learning gains depend strongly on instructional method and practice structure rather than on the delivery medium alone [19,48]. In Tai Chi, visual representation must also be converted into embodied execution; without haptic guidance, expert correction, or repeated practice, immersive visualization alone may be insufficient to outperform a carefully designed video after a single session [8,48]. Recent evidence indicates that motor benefits are more likely to emerge in repeated, adaptive, or higher-dose VR training than in a single exposure [21-23]. The null between-group result means that the experiential findings should be interpreted separately from claims of improved learning [15,19,32].

Game Experience

The clearest between-group differences were in game experience. VR participants reported higher competence and flow and lower tension, while negative affect was comparable across conditions. These results do not support the assumption that older adults necessarily experience head-mounted displays as more stressful or intimidating [49]. One possible explanation is that VR created a more private, less socially evaluative practice context by reducing external distractions and limiting visible comparisons with others [16,50,51]. This interpretation remains speculative because the study did not directly measure perceived privacy, social-evaluative threat, self-consciousness, or cognitive load. The headset-based setting may have supported concentration and perceived control, but that mechanism requires direct testing [15,16,52].

Intrinsic Motivation and Learning Engagement

Notably, the advantages observed in the game experience did not extend to intrinsic motivation, general engagement, or posttest movement-encoding performance. This dissociation is theoretically informative. Higher perceived competence in VR may reflect a stronger immediate sense of control or confidence in the practice environment, but that feeling did not translate into superior movement-encoding scores within a single session. It is also possible that the immersive presentation induced overconfidence, or that the outcome measure captured cognitive representation more than actual execution quality. Measures such as flow, tension, and perceived competence are sensitive to immediate task conditions, whereas stable motivational orientations, generalized engagement, and measurable motor learning may require repeated exposure, autonomy-supportive scaffolding, and longer time horizons to shift [52-54].

Importantly, differences between GEQ and IMI on conceptually similar dimensions (eg, tension or pressure) may reflect item-level nuance rather than contradiction [37,38,55]. GEQ tension items tend to capture situational frustration or irritation during interaction, whereas IMI pressure or tension items more directly reflect performance-related anxiety or feeling pressured to do well [38]. In this study, immersive VR may have reduced interaction-related tension without materially changing performance-evaluative pressure, which could remain salient in a single-session learning context [54,56]. This dissociation suggests VR operates more as an interface and interaction buffer than a direct remedy for performance anxiety, highlighting design opportunities (eg, supportive feedback or guided practice) to target the latter [16,53,57].

Safety, Tolerability, and Feasibility

The safety profile was encouraging but not uniform. Simulator-sickness symptoms were generally low among VR participants with valid data, and most completers reported no symptoms. At the same time, attrition related to motion sickness and technical problems was not trivial and forms part of the intervention's feasibility and tolerability profile [24,28-30,49]. These exclusions show that acceptability varies across individuals and hardware-software circumstances [24,28-30,49]. Symptom estimates reflect participants who remained in the protocol; therefore, safety conclusions should acknowledge possible survivorship bias and the need for structured screening and monitoring in real-world use [24,28,30,49]. The favorable experiential profile among VR completers may not generalize to older adults who are more susceptible to motion sickness or device-related discomfort.

Practical Implications for Community Implementation

Because the intervention was delivered in community and village activity rooms, the study provides initial evidence of supervised use outside a laboratory [17,24,28,58,59]. For short-term movement-encoding knowledge, no between-group difference was detected; the distinctive findings for VR concerned competence, flow, and tension [16,19,34]. The study did not measure long-term adherence, so implications for sustained participation remain untested. Three practical safeguards are suggested by the feasibility results: (1) brief prescreening for motion sensitivity and comfort with head-mounted displays, (2) gradual exposure with short initial bouts, and (3) reliable on-site support for headset fit, tracking, and interruptions [28,49,58]. VR telemetry may also inform future feedback design and training adjustment [34,58], but these process measures are not interchangeable with learning outcomes. Finally, VR differed from video in immersion, interactivity, embodiment, and sensorimotor coupling; the present design cannot isolate those components.

XSL•FO
RenderX

Limitations and Threats to Interpretation

Several limitations shape interpretation. First, the primary outcome was a brief movement-encoding knowledge test that emphasizes cognitive representation, recall, and recognition of movement elements more than objective movement quality; it cannot establish actual Tai Chi execution, long-term retention, transfer to real-world practice, or expert-rated motor competence [8,32,49]. Second, the analysis focused on immediate posttest performance; comparative benefits of VR may emerge more clearly in delayed retention, transfer, or adherence over time [8,28,49]. Third, the primary analysis required complete pretest and posttest data, while VR-specific attrition due to sickness and technical failure constrains generalizability and should be addressed as an outcome in its own right [28,49]. Fourth, randomization was not stratified by age or prior Tai Chi experience, and the Video Group was older at baseline. Age was controlled in the primary analysis, and exploratory analyses offered no evidence that age modified the intervention effect; however, future trials should consider stratified randomization or minimization procedures.

Future Directions

Future research should move beyond binary comparisons toward mechanism-driven and heterogeneity-driven designs [58,60]. A priority is to test the proposed immersive-shielding pathway by directly measuring social-evaluative threat, perceived privacy, self-consciousness, cognitive load, and self-efficacy as potential mediators linking condition to tension and flow [10,16,50]. Studies should add objective motor metrics (expert ratings, kinematic measures, or pose estimation) to determine whether experiential advantages translate into cleaner movement execution or safer performance under balance demands [16,32]. Longer follow-up is needed to evaluate retention, transfer, and adherence, domains where reduced tension and higher perceived competence may prove consequential but were not tested here [8,15,16]. Finally, safety should be modeled proactively: rather than treating cybersickness as incidental, future trials should identify predictors of intolerance and establish screening and adaptive onboarding protocols so that immersive training can be targeted to those most likely to benefit while minimizing risk for those vulnerable to adverse symptoms [28,49,58].

Conclusions

In this randomized study, immersive VR did not produce higher short-term Tai Chi movement-encoding knowledge than standardized video instruction after adjustment for baseline performance and age [61,62]. Among participants who completed the VR session, perceived competence and flow were higher and tension was lower, suggesting a more favorable immediate game-experience profile [31,62]. These experiential findings do not establish superior learning or motor execution. Discomfort-related withdrawals and technical exclusions also place clear limits on feasibility and generalizability [63-65]. Overall, VR may be useful when experiential engagement is a priority, but the present results do not show an advantage over video for immediate movement-encoding performance.

Abstract

Background: Keep-on-Keep-up Nutrition (KOKU-Nut) is a free, tablet-based digital platform that focuses on increasing physical activity and improving the dietary intake of older adults.

Objective: The aim of this study was to assess the feasibility of using KOKU-Nut among community-dwelling older adults. Feasibility was assessed by considering recruitment and retention rates, acceptability of the intervention, and study design.

Methods: Participants (community-dwelling adults aged ≥65 years) were randomized 1:1 to either the intervention or control group. The intervention group was asked to engage with KOKU-Nut 3 times a week for 12 weeks. Participants in the control group received a leaflet promoting a healthy lifestyle. All participants completed questionnaires at baseline and 12 weeks. A sample of participants was asked to complete an optional interview. The study collected data on dietary intake (24-hour food diary), physical function (grip strength and 5-time sit-to-stand exercise), usability of the intervention (System Usability Scale), and safety (adverse events).

Results: Of 51 participants assessed for eligibility, 31 were randomized, and 28 completed the 12-week follow-up. Of the 14 participants in the intervention group, 10 (71.4%) reported engagement with KOKU-Nut 3 or more times a week. There was no difference in physical function or dietary intake at 12 weeks between participants in the intervention and control groups after adjusting for age and baseline values.

Conclusions: This feasibility randomized controlled trial indicates that the study design was appropriate and acceptable to older adults, as demonstrated by the recruitment and retention rates. This is promising and demonstrates the potential for conducting a future powered randomized controlled trial to assess the effectiveness of KOKU-Nut.

KEYWORDS

feasibility; digital health; malnutrition; older adults; nutrition

Introduction

Data from the Office for National Statistics show that, in 2016, there were 11.8 million UK residents aged 65 years and over, representing 18% of the UK population [1]. Projections for 2066 estimate that this will increase by 8% to 20.4 million people [1]. Despite increases in life expectancy, healthy lifespan is not increasing at the same rate, and these additional years are often spent in poor physical and mental health [2].

Malnutrition is common among older adults and often arises from an interplay of physiological, psychological, and social factors, including dysphagia, chewing difficulties, bereavement, social isolation, and mobility limitations, all of which can influence nutritional intake [3-6]. Estimates suggest that approximately 8.5% of community-dwelling older adults are at risk of or experience malnutrition [7]. Observational and experimental evidence demonstrates that a healthy diet can slow disease progression, reduce the rate of functional decline, and prevent undernutrition and frailty [5,8-11], whereas the presence

XSL•FO
RenderX

of malnutrition leads to adverse health outcomes, premature mortality, and increased costs on health and social care [12,13]. Older adults living in the community are likely to have greater independence and choice regarding their dietary intake than individuals living in care homes or hospital settings, where meals and food provision are more structured and institutionally regulated [14]. A James Lind Alliance Priority Setting Partnership identified that early intervention in vulnerable groups was the number one research and innovation priority for adult malnutrition [15]. This highlights the need and rationale to support the nutritional intake of older adults to help prevent malnutrition

An aging population with high health care demands [1] coupled with technological advances creates an opportunity for innovative digital solutions to support health care [2,16,17]. Keep-on-Keep-up is a National Health Service–approved digital fall prevention program designed with and for older adults [18]. The platform includes progressive strength and balance exercises [19-21], gamification to improve awareness of bone health and safety in the home, and behavior change techniques to support users in building habits and tracking behaviors. Keep-on-Keep-up Nutrition (KOKU-Nut) is the latest iteration [6,22], providing nutrition advice to complement the strength and balance exercises. Multi-domain interventions appear to have greater benefits for functional outcomes in older adults [23] given that adverse health in older age often encompasses multiple deficits across multiple domains [24].

The aim of this study was to assess the feasibility of conducting a randomized controlled trial using the digital platform KOKU-Nut to improve dietary intake in community-dwelling older adults. Feasibility was assessed by considering recruitment and retention rates and acceptability of the study design. This study also considered the usability, preliminary efficacy, and safety of KOKU-Nut.

Methods

Overview

A sequential mixed methods study design was chosen that used quantitative and then qualitative research techniques given the difficulty of evaluating a complex intervention and to maximize the breadth and depth of the research findings. The protocol was previously published [22], and the trial was registered prior to recruitment (NCT05943366). This study was reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [25] to ensure comprehensive and transparent reporting of the qualitative methods and findings (Multimedia Appendix 1).

Ethical Considerations

Ethics approval was obtained from the University of Manchester Research Ethics Committee on August 18, 2023 (reference 2023-17372-30569), and this study complied with the Declaration of Helsinki. Written informed consent was obtained from all participants prior to commencement of the research.

Eligibility Criteria

Participants were included in the study if they were aged 65 years and older, living independently in the community in Greater Manchester, and willing to use an iPad or tablet (their own or one provided by the research team) for the duration of the study. Participants were excluded if they were unable to communicate in English or had a known cognitive impairment.

Recruitment and Sampling

Men and women aged 65 years and older living independently in the community were recruited on a rolling basis through purposive sampling via local Age UK groups, assisted living facilities, and university networks. Initially, a phone call was arranged to determine eligibility. The researcher verbally explained the aims of the study, how data were collected, and what was required from participants and encouraged participants to ask any questions or raise any concerns.

Recruitment to the qualitative study was done purposefully toward the end of the intervention period to recruit a demographically representative group of participants, including variation in sex, age, and treatment group. Researchers continued to invite participants until data saturation was reached, defined a priori as the point at which no new themes emerged from successive interviews during data coding and charting.

Randomization

Upon meeting the eligibility criteria and providing written informed consent, participants were randomized into either the intervention or control group by an independent member of the research team using sealedenvelope [26]. Participants were informed of their group allocation after baseline data had been collected.

Study Intervention

KOKU-Nut [6] is a digital platform that can be downloaded on tablet or iPad devices. The platform includes progressive and personalized strength and balance exercises alongside a suite of educational games, including a nutrition matching pair card game to educate and nudge users to support their dietary intake (see Multimedia Appendix 1 for screenshots). In particular, the educational content focuses on (1) increasing intake of high-quality protein items such as milk, yogurt, and fish; (2) increasing fluid intake to 6 to 8 glasses a day; and (3) educating users on the signs and risks of malnutrition.

Participants in the intervention group were asked to engage with KOKU-Nut in their own time for approximately 30 minutes 3 times a week for 12 weeks. At the baseline visit, participants were supported with downloading the digital platform onto their iPad or tablet. In cases in which participants did not have the necessary device to use the intervention, an iPad (Apple Inc) with KOKU-Nut installed was provided to the participants for the duration of the intervention. The researcher explained and demonstrated the features of the digital platform and assisted with any technical queries. A crib sheet and contact details for the researcher were provided to participants for additional support and to help with technical issues. A family member or friend was invited to attend the baseline visit if the participant

XSL•FO
RenderX

wanted additional support. Participants were advised to continue their usual care and treatment.

Control Group

Participants assigned to the control group received a leaflet developed by Age UK that contained information about the importance of a healthy lifestyle, including the benefits of staying active and eating healthy [27]. Participants in the control group were also advised to continue with usual treatments and care from their health care professionals.

Data Collection

Written informed consent was collected from all participants prior to collecting the baseline case report file or conducting any assessments at the participants' homes. The baseline case report file collected data on the participants' sociodemographic characteristics, as well as the following measures. Health-related quality of life was assessed using the EQ-5D-5L, which considers mobility, self-care, usual activities, pain and discomfort, and anxiety and depression [28]. Each domain is rated across 5 levels of severity, which are combined and converted into a single summary value [29]. The instrument also includes a visual analog scale, where participants rate their overall health from 0 (worst health imaginable) to 100 (best health imaginable). Risk of malnutrition was assessed using the validated Malnutrition Universal Screening Tool [30], and overall risk was assessed as a binary measure to compare those with low vs medium or high risk of malnutrition. Mood was assessed using the short version of the Geriatric Depression Scale [31]. Items were scored dichotomously and summed; overall risk was then assessed as a binary variable so that participants scoring 2 or higher were at risk of depression. These assessments were chosen due to their ease of administration, relevance to the research question, and widespread use across community and clinical settings in the United Kingdom.

During the baseline and 12-week assessments, the researcher also measured grip strength (in kilograms), the time taken to complete 5 sit-to-stand exercises (seconds), and frailty status based on the Clinical Frailty Scale. Further details on these procedures are provided in the study protocol [22].

Participants were asked to complete a 24-hour dietary recall using the online questionnaire Intake24 (version 2) at baseline and 12 weeks [32,33]. Participants were encouraged to follow usual food and drink consumption and then report all food and drink consumed in the online software as accurately as possible. If participants were unable to access Intake24 or experienced technical difficulties, the researcher input this information based on a paper-based version of the participants' food diary.

The researcher arranged the follow-up assessment 12 weeks after the baseline visits. Baseline measurements were repeated, and participants in the intervention group also reported outcome data related to the usability and acceptability of the intervention, assessed using the technology acceptance model (TAM) [34] and System Usability Scale (SUS) [35].

A subsample of participants completed one-to-one semistructured interviews at the end of the intervention period with a female researcher (CF) experienced in qualitative methodology. Interviews were conducted online or face-to-face based on the preference of the participant, audio recorded, and expected to last no more than 60 minutes. Prior to completing the interview, participants provided additional consent regarding the recording, storage, and use of their interview data. A topic guide was informed by the research aims and similar studies and was used to explore barriers to recruitment, the appropriateness of the outcome measures, and the feasibility of implementing the KOKU-Nut intervention.

Outcomes

The main outcome was the feasibility, acceptability, and usability of the KOKU-Nut digital platform (Multimedia Appendix 1). Additional outcomes were the potential benefits of engaging with KOKU-Nut, specifically considering protein intake, risk of malnutrition, physical function, and health-related quality of life, as previously described [22].

Statistical Analysis

Feasibility outcomes and baseline characteristics of the participants were summarized using descriptive statistics, including proportions or means with SDs. Between-group differences in health-related measures at 12 weeks were explored using analysis of covariance adjusting for baseline values of the outcome and participants' age at recruitment. These analyses were conducted on an exploratory basis to provide preliminary estimates of potential intervention effects. Given the feasibility nature of the study, the sample size was not powered to detect statistically significant differences.

Interviews were transcribed verbatim and then checked by a researcher to ensure accuracy. Transcripts were then managed using NVivo (version 12; Lumivero) [36] and analyzed inductively using the 5 stages of framework analysis [37,38]. The initial stage involved repeatedly reading the transcripts, followed by the development of codes and the identification of an initial thematic framework (CF). Subsequently, data were systematically indexed according to this framework. The fourth stage involved organizing and summarizing the data into thematic charts to facilitate comparison and synthesis. Finally, patterns within the data were interpreted and discussed with all coauthors to generate overarching insights. To enhance analytical rigor, all stages of the process were reviewed and discussed by a minimum of 2 researchers.

Results

Sociodemographic Characteristics of the Participants

Table 1 shows the baseline characteristics of all 31 participants enrolled in the study. The mean age was 81.3 (SD 8.3) years, and most participants were female (n=24, 77.4%) and White (n=27, 87.1%). Almost all (n=28, 90.3%) participants were retired, and just under half (n=14, 45.2%) were widowed. Overall, most participants were at a low risk of depression based on the 5-item Geriatric Depression Scale. In total, 12.5% (2/16) of the participants in the intervention group were at risk of depression at baseline, which may have affected motivation to use and engage with KOKU-Nut.

XSL•FO
RenderX

More than half (16/31, 51.6%) of participants were taking 5 or more medications, and there were more participants with polypharmacy in the intervention group (10/16, 62.5%) compared to the control group (6/15, 40%). More than half (16/31, 51.6%) of all participants self-reported one or more falls in the previous 12 months, and fall history was similar between the 2 groups. At baseline, 16.1% (5/31) of the participants were at risk of malnutrition based on a score of 1 or more on the Malnutrition Universal Screening Tool, and there was no difference in risk between the groups. The median frailty score was 4 (IQR 3-5), indicating that the sample was living with very mild frailty. This has been described as “while not dependent on others for daily help, often symptoms limit activities.” A common concern is being “slowed up” and/or being “tired during the day” [39].

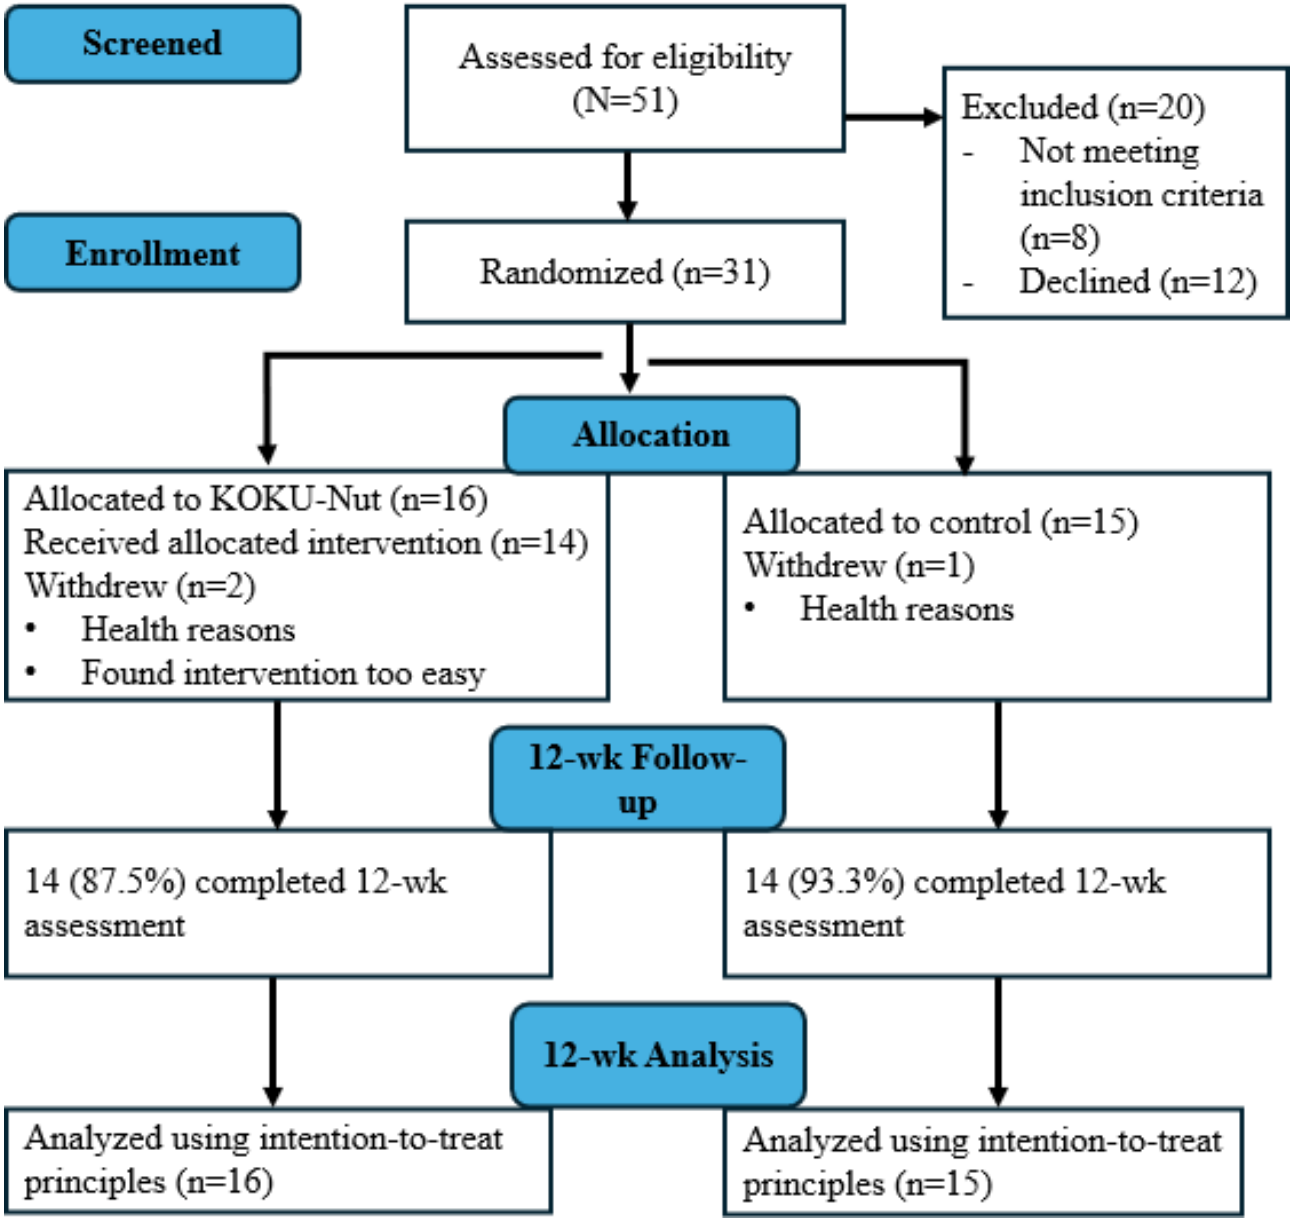
Feasibility Outcomes: Recruitment and Retention

Overview



Between March 2024 and August 2024, a total of 51 potential participants were screened to participate in the study, of whom 8 (15.7%) were excluded because they did not meet the eligibility criteria (n=5 were aged <65 years, n=1 lived outside of Greater Manchester, and n=2 had mild cognitive impairment); a further 12 (23.5%) older adults declined to participate.

In total, 31 older adults were enrolled in the study and randomly assigned to the intervention (n=16, 51.6%) or control (n=15, 48.4%) group (Figure 1). Prior to the 12-week follow-up, 12.5% (2/16) of the participants in the intervention group withdrew (one had a knee operation, and the other found the KOKU-Nut program too easy). In total, 6.7% (1/15) of the participants in the control group withdrew because they had a fall and no longer wanted to take part. As a result, the overall retention rate at the 3-month follow-up was 90.3% (28/31). The study was completed with high retention rates and low levels of missing data; these indicators suggest that the study is feasible (Multimedia Appendix 1). It may be beneficial to have more targeted recruitment strategies to increase recruitment rates and support the conversion of eligible to enrolled participants in a future trial.

Ten participants completed an interview, 6 of whom were in the intervention group, and the remaining 4 were in the control group. Interviews were conducted face-to-face at the participants' homes and lasted for a mean of 31.5 (SD 12.1; range 18-51) minutes. Framework analysis of the dataset uncovered 3 key themes.

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. KOKU-Nut: Keep-on-Keep-up Nutrition.

Theme 1: Acceptability of the Study

Participants found the questionnaires and physical function tests acceptable; however, there was some resistance regarding the 24-hour dietary recall. The experience of using the online software was variable: some found it interesting to consider the different portion sizes, whereas others were unable or did not want to use the online software and so completed an interviewer-led version. Participants also reported changing their intake to facilitate the recording process or having difficulty entering certain foods:

> *I was very interested in it [Intake24 survey] and the way it was done, particularly with the measurement of quantities and the options you were given which I thought were very helpful...and I actually enjoyed it.* [Female participant; control group]

> *I had a word with a couple of people and described what I had done so far, they found the idea of the meal report off-putting.* [Female participant; intervention group]

> *I omitted some foods as it was tedious to complete, especially when making food from scratch. I didn't know how to enter homemade soup or cake.... It felt like it was tailored towards someone who would buy a lot of pre-packaged foods, also it doesn't ask about salt and pepper.* [Female participant; intervention group]

> *First time I picked the simplest meal that I ever eat.... But the second time I picked a slightly more complicated one.* [Female participant; control group]

In general, the intervention (KOKU-Nut) was acceptable, beneficial, and enjoyable, although there were still some concerns about the digital aspect:

> *Have found that since making changes I have more energy. Used to experience an afternoon slump*

XSL•FO
RenderX

> *around 3pm but now I feel more energised.* [Female participant; intervention group]
>
> *For people that are familiar with tablets it would be fantastic.... But I've got friends in their seventies and eighties who don't use smartphones!* [Male participant; intervention group]

Theme 2: Healthy Behaviors

Many participants in both the intervention and control groups highlighted that taking part in the study made them reflect on their health and their current dietary choices, which made them want to make positive changes. Participants in the intervention group found that using KOKU-Nut prompted them to consider their health and start a new routine:

> *Since [starting the study, I] made small changes to diet and exercise routine and app nudged me in the right direction.* [Male participant; intervention group]
>
> *I want to be active and independent for as long as possible and this provided encouragement to make small changes.* [Female participant; control group]
>
> *I now try to get protein at each meal.... So yes, I've introduced yoghurt on top of the porridge.* [Male participant; intervention group]
>
> *Since starting the study have made an effort to increase protein so now, I check the packaging to look for grams of protein to ensure that having protein with all meals.* [Female participant; intervention group]
>
> *KOKU has made me more conscious of cooking and what we can and should be having for a healthy diet.* [Female participant; intervention group]

Participants also recognized the importance of habit formation and that incorporating KOKU-Nut into their routine helped with engagement:

> *I think it might be good for people to think about where and when they use it and how it can fit in with their routine.* [Female participant; intervention group]

Participants in the control group also highlighted that the study prompted them to make more positive lifestyle changes, with one participant saying the following:

> *And then I was thinking it's not just your physical health, you've got to think of your mental health as well. So, I've signed up to do Tai Chi on a Monday.* [Female participant; control group]

However, participants identified the limitations of using a booklet to support behavior change:

> *The thing with a booklet is, you read it and then you put it to one side and then that's it. And if you need prompting there isn't anything there.* [Female participant; control group]

Theme 3: Future Considerations

Participants highlighted additional features that they thought would add value to KOKU-Nut and support them in making positive changes to their diet. This included a myth-busting information section, an example week's menu, or recipe ideas with video and written content:

> *Due to my hypertension I never know if I can have cheese or yoghurt so it would be great to have information about if I can eat these foods.* [Female participant; intervention group]
>
> *It would be great to have more nutrition advice and content for example to explain what a high protein diet actually is.* [Male participant; intervention group]
>
> *I'd find it very useful to have videos or written recipes with an example weeks menu...or even just some recipe inspiration.* [Female participant; intervention group]

Additional Outcomes

Usability and Safety of the Intervention

Of 14 participants in the intervention group, 10 (71.4%) self-reported engagement with KOKU-Nut 3 or more times a week as suggested at the start of the intervention. Of 16 participants in the intervention group, 11 (68.8%) received an iPad provided by the research team, and 5 participants (31.2%) had their own devices. Based on the SUS, KOKU-Nut had very good usability, with a mean score of 79.7 (SD 15.2), above the industry standard average of 68 [40]. Participants with their own iPads provided slightly higher and more consistent usability scores (mean 82, SD 6.2) compared to participants who did not have their own iPad (mean 78.6, SD 18.7). There were no adverse events reported over the 12-week period.

User Experience

Fourteen participants considered the acceptability of KOKU-Nut based on the TAM as this was not completed by the 2 participants who withdrew from the study. Participants rated the nutrition game highly on perceived ease of use, perceived usefulness, attitude toward use, and intention to use (Multimedia Appendix 1). There was moderate correlation between perceived usefulness and attitude toward and intention to use (Table 2). This is important as the TAM suggests that there is an association between the user's intention to use the technology and their actual use behavior [41].

XSL•FO
RenderX

Table . Technology acceptance model questionnaire for community-dwelling older adults and their experience of using Keep-on-Keep-up Nutrition (KOKU-Nut). Each aspect was scored on a scale ranging from 0 to 7 such that 7 represented "most favorable" (ie, highest level of perceived usefulness). There were missing data from 2 participants in each case due to withdrawals.

	Perceived ease of use	Perceived usefulness	Attitude toward use	Intention to use
Scores, median (IQR)	6.3 (5.4-7.0)	5.3 (4.9-5.9)	6.9 (5.9-7.0)	5.3 (3.7-6.3)
Correlation with intention to use, Pearson r (*P* value)	0.3 (0.27)	0.5 (0.05)	0.65 (0.01)	—[a]

[a]Correlation between intention to use and intention to use is not reported.

Preliminary Effectiveness of the Intervention

Participants undertook assessments of functional ability, dietary intake, and quality of life at baseline and the 12-week follow-up. An exploratory intention-to-treat analysis was conducted, but as this was a feasibility study, it was not sufficiently powered to detect significant differences between groups.

There was no difference in grip strength or time taken to complete 5 sit-to-stand exercises at the follow-up assessment between groups after adjusting for age and baseline values.

EQ-5D-5L scores were similar between the groups at baseline and reflect the norms for this age group [42]. After the 12-week intervention, there was a difference in EQ-5D-5L scores using analysis of covariance ($F_{1,27}$=7.26; *P*=.01), again adjusting for age and baseline values. Participants in the intervention group had higher mean EQ-5D-5L scores than participants in the control group (at 12 weeks; 0.72, 95% CI 0.67-0.78 vs 0.62, 95% CI 0.57-0.78 in the control group; *P*=.01).

Table 3 shows that baseline mean protein intake was above the reference nutrient intake of 0.75 grams per kilogram of body weight per day [43,44]. There was no difference in energy (kilocalories per day) or protein (grams per kilogram of body weight per day) intake at the follow-up assessment between participants in the intervention and control groups when adjusting for baseline values (Table 3).

Table . Physical function and nutrition outcomes at baseline and 12 weeks by treatment group in community-dwelling older adults (N=31).

Parameter	Baseline, mean (SD)	Week 12, mean (SD)	*P* value
Grip strength (kg)			.77
Intervention	20.19 (11.95)	20.31 (10.07)	
Control	18.33 (6.34)	18.47 (6.39)	
5-STS[a] (s)			.27
Intervention	26.08 (16.98)	24.27 (17.10)	
Control	29.82 (17.07)	30.53 (16.46)	
Energy intake (kcal per d)			.80
Intervention	1459 (468)	1415 (455)	
Control	1548 (468)	1432 (227)	
Protein intake (grams per kilogram of body weight per d)			.87
Intervention	1.00 (0.29)	1.01 (0.32)	
Control	0.96 (0.33)	0.97 (0.24)	
EQ-5D-5L (−0.59 to 1)			.01
Intervention	0.68 (0.27)	0.74 (0.21)	
Control	0.64 (0.22)	0.60 (0.22)	
VAS[b] (0-100)			.61
Intervention	81.10 (18.53)	79.94 (13.96)	
Control	77.73 (17.63)	75.33 (15.41)

Discussion

Principal Findings

This 12-week intervention informed by the Medical Research Council guidelines for the development and evaluation of a complex intervention [45] in older adults living in the community in Greater Manchester was feasible and acceptable. Participants reported high usability of KOKU-Nut and found the digital platform acceptable and easy to use, as demonstrated by the SUS [35] and TAM [34]. The current study had retention rates above 90%, and framework analysis of the interviews demonstrated that the study design, assessments used, and allocated treatment groups were acceptable to participants.

This study managed to recruit an at-risk population with low attrition at 12 weeks (3/31, 9.7%). Participants had a mean age of 81.3 (SD 8.3) years, ranging from 70 to 96 years. At baseline, more than half (10/16, 51.6%) of the sample had fallen at least once in the previous 12 months, 16.1% (5/31) were at risk of malnutrition, and most of the participants (median score 4, IQR:3,5) were considered vulnerable according to the Clinical Frailty Scale.

The KOKU-Nut intervention had no impact on energy or protein intake and physical function outcomes at 12 weeks; however, this was a feasibility study with a small sample size and, thus, not powered to detect statistical differences. In addition, interpretation of these findings is further limited by the baseline characteristics of the sample, who were well nourished with adequate protein intake of approximately 1 gram per kilogram of body weight per day at baseline [46]. This introduces a potential ceiling effect whereby participants were already meeting dietary requirements and limits the scope for measurable improvement. Future trials should consider additional eligibility criteria to recruit individuals with suboptimal dietary intake at baseline to enhance sensitivity to change and increase the likelihood of detecting a meaningful intervention effect. Increasing protein intake can support the anabolic effects of strength training and minimize age-related muscle loss, and this has previously been demonstrated in older adults [47], including those with frailty [48] and sarcopenia [49]. However, these dietary interventions did not use a digital platform, and very few apps simultaneously improve dietary intake and support strength training in this population [50]. The study by van den Helder et al [51] demonstrates that combining a home-based exercise program delivered via a tablet-based app with dietary protein counseling delivered via face-to-face dietitian sessions can effectively increase protein intake in older adults. Additional work should focus on the development of a digital tool to support dietary intake among older adults. Additional educational games, high-protein recipes, and goal-setting features are likely to support users in changing their behavior, promote protein intake, and increase the effectiveness of KOKU-Nut.

Most participants in the intervention group (10/14, 71.4%) self-reported using KOKU-Nut 3 or more times a week, demonstrating a satisfactory level of adherence to the intervention. This indicates that older adults can regularly and independently engage with a digital platform such as KOKU-Nut even without prior experience of using an iPad or tablet. A feasibility study with 25 older adults found that 80% of participants regularly used a tablet-based self-monitoring nutrition app (Appetitus) [52]; this complements findings from the current study demonstrating the potential to engage older adults with digital nutrition tools, but further research is required on long-term use and effectiveness. Despite high levels of engagement and usability in the current study, future digital interventions may benefit from increased involvement of caregivers or family members, particularly for those with lower digital literacy, to support confidence, engagement, and uptake.

Unlike the interactive KOKU-Nut intervention, the leaflet-based control condition provided a relatively passive form of intervention delivery. Leaflets are often provided to this population for health guidance and information and, thus, reflect treatment as usual; however, an active control condition may provide greater insight into the effectiveness of the KOKU-Nut intervention. Moreover, qualitative findings indicated perceived behavior change in participants across both trial arms, suggesting that study participation itself may have influenced diet and lifestyle behaviors. This is likely influenced by self-monitoring effects associated with completing assessments and heightened motivation due to involvement in a research study.

This study had many strengths. The approach aligns with the Medical Research Council framework for the development and evaluation of complex interventions [45]. The mixed methods design provides a more comprehensive and nuanced understanding of the feasibility and delivery of the study compared to either methodology alone. Attrition bias was low given that this study had a 90.3% (28/31) retention rate, with only 3 participants dropping out during the 12 weeks. This demonstrates that it was possible to recruit and retain a group of older adults who are at a high risk of falls and often not included in research. Moreover, KOKU-Nut is a minimally invasive digital intervention, so it would be suitable for wide-scale implementation, and a small effect in a large population has the potential to have a big overall effect with low cost or risk.

There are also several limitations that must be acknowledged. Participants were unaware of their allocation until after completing baseline assessments; however, randomization had already been performed prior to the assessment. The lack of allocation concealment may introduce selection bias. This study was not blinded due to resource constraints that, again, may introduce detection bias. This study could have compared the use of KOKU-Nut with that of a generic health app that was not designed for this population to blind the intervention. However, due to limited access to iPads, the control group received a leaflet explaining the benefits of healthy lifestyle habits, and this is likely to better represent standard practice or usual care. The nutrition game was embedded into the Keep-on-Keep-up app, and therefore, it was not possible to specifically look at engagement with the nutrition component or identify whether self-reported use and improvements in quality of life were related to the nutrition game or a different part of the digital platform. Engagement with the digital platform was self-reported, so future studies should aim to develop a dashboard or use Google Analytics data to capture use time

XSL•FO
RenderX

objectively. Methodologies to inform the best practice to conduct a gold-standard clinical trial for a digital intervention should be prioritized. Although many assessments were objective, dietary recall is often subject to recall and response bias from underreporting and poor memory. Dietary assessment is prone to misreporting of portion sizes and foods for social approval [53-55]. Moreover, the qualitative work highlighted challenges with completing the 24-hour recall, including burden, difficulties entering complex or homemade foods, and a tendency to simplify intake to facilitate recording. These issues suggest that dietary assessment tools may require greater flexibility and user support to reduce respondent burden and improve data completeness.

Conclusions

Overall, this feasibility randomized controlled trial demonstrates that the study design was appropriate and acceptable to older adults, as indicated by the recruitment and retention rates as well as the themes that emerged from the interviews. This is promising and demonstrates the potential for conducting a larger study in the future that will be powered to detect effectiveness.

KOKU-Nut had good usability, acceptability, and engagement according to the SUS, TAM, and self-report use, indicating that the intervention was designed appropriately to engage this population. However, the exploratory outcomes exhibited no difference in physical function or dietary intake. This demonstrates that further developments should be made to KOKU-Nut to support dietary change before conducting a larger study to see whether KOKU-Nut can lead to clinical and meaningful impact.

Abstract

Background: Digital technologies have the potential to support physical, cognitive, and social activity among older adults, but many small- and medium-sized enterprises (SMEs) lack the resources to conduct meaningful co-design with older adults. Toolkits derived from rigorous co-design processes may offer a scalable mechanism for translating end-user priorities into real-world product development.

Objective: The Generating Older Active Lives Digitally study aimed primarily to engage older adults in a co-design process to identify priorities for digital technologies that support physical activity and reminiscence. Secondary objectives were to (1) translate these findings into a practical developer-facing toolkit, and (2) evaluate the toolkit's perceived utility and influence among digital technology SMEs.

Methods: A total of 157 participants (121 older, 7 younger, and 29 staff) across 15 community and care settings in England and Scotland engaged in 106 technology interaction sessions, 22 evaluation focus groups, and 10 co-design workshops. These involved more than 20 digital technologies. Thematic analysis and structured card-ranking tasks were used to derive their priorities. Preliminary toolkits were co-designed and used by 10 UK-based SMEs who received small grants to apply the toolkit to active development projects. Their reports and follow-up interviews were analyzed thematically to identify perceived impacts on design decisions, product adaptations, and business outcomes.

Results: Co-design activities generated 7 cross-cutting themes: motivation, content, barriers, design and inclusivity, suitability, acceptability, and motivations to use. These were organized into 3 toolkit sections: general design principles, online physical-activity platforms, and virtual reality. SMEs reported that the toolkits enhanced understanding of older adults' needs, validated design decisions, and inspired some new features. Perceived impacts included improved usability, expanded accessibility options, increased content variety, clearer instructional design, enhanced social components, and reduced operational costs. SMEs also reported some business benefits, including strengthened cases for investment and increased product uptake.

Conclusions: Co-designed toolkits may offer a useful and cost-effective mechanism for translating older adults' priorities into digital product development. SMEs perceived this toolkit as practical, relevant, and impactful for informing design choices. This approach may complement, but does not replace, direct user involvement. It may help accelerate inclusive digital-health innovation for aging populations.

Introduction

Background

It is expected that by 2030, a total of 1 in 6 people in the world will be aged older than 60 years, and by 2050 the world's older population will have doubled [1]. This demographic shift is placing increasing pressure on health and social care systems, leading to a growing emphasis on promoting healthy aging across the life course [2]. A key focus within this agenda is promoting physical activity within older populations given the role it can play in maintaining and improving physical function [3]. Another area of focus is that of building older adults' social connectedness and well-being through reminiscence, which has been shown to benefit well-being [4]. Sports-based reminiscence has been particularly successful in men with cognitive impairment, providing, among other mechanisms, a source of specific interest on which to hinge opportunities to increase social participation [5].

Digital technologies have been proposed as a means of supporting physical, cognitive, and social activity in later life [6]. National policies, such as the UK government Consensus on Healthy Aging [7], promote physical, cognitive, and social activity among older adults through exercise, games, reminiscence, and social connection, with digital tools playing a key role. In response, a wide range of digital technologies has emerged, including online exercise platforms, mobile apps, exergames, and immersive virtual reality (VR) experiences. Recent reviews [8,9] covered 16 - 22 studies on technologies to support physical activity, while another study [10] identified 13 apps and 24 websites for promoting strength and balance exercises. Positive effects of online exercise platforms or programs designed for older adults have been found for body strength, flexibility, and balance [11,12]. More recently, VR tools designed to support physical activity and reminiscence in older adults have shown promising benefits. These include improved physical rehabilitation at home [13], positive influences on cognition, memory, and depression [14], and enhanced cognitive and social engagement through reminiscence experiences [11,15]. Despite these advances, older adults often experience challenges when adopting and sustaining engagement with digital technologies. Many report positive attitudes toward the potential usefulness of technology to increase their physical and social activity [16]. However, barriers related to usability, accessibility, confidence, cost, security, and perceived relevance frequently result in poor adoption or disengagement [17]. Evidence suggests that when technologies are well-designed, have clear training or guidance, have adaptations specifically for older adults, highlight the benefits, and focus on an older person's values, conditions, and reducing age-related risks, they can successfully adopt and make use of them [16,18]. However, research has identified the disconnect between what a technology developer may believe an older adult would like or need from the technology and what older adults prioritize [19]. They need to understand the needs and preferences of older adults in using digital products [20-22].

Co-design is widely regarded as a gold-standard approach for addressing this disconnect in digital development. It is the practice of people collaborating and connecting their knowledge, skills, and resources to carry out a design task and to produce new knowledge as people experiment with new ideas [23]. It differs fundamentally from user surveys and market research in that it positions users as active partners in the design process rather than passive respondents. Surveys and market research are valuable for identifying preferences, patterns, and trends, but are typically developer-led and often constrained by predefined questions. In contrast, co-design engages users in generative activities such as ideation, critique, and prototyping. This enables the incorporation of lived experience and tacit knowledge into intervention development. This participatory approach has been associated with improved relevance, acceptability, and implementation of health interventions (eg, other studies [24,25]). As a result, co-design supports successful and relevant design [26] and business growth [27]. However, meaningful co-design can be resource-intensive, requiring time, expertise, and sustained engagement that may be beyond the capacity of small and medium-sized enterprises (SMEs). Further, evidence suggests that poorly implemented co-design offers little advantage over standard design practices [28]. Consequently, alternative mechanisms are needed to support SMEs in integrating end-user insights without requiring them to conduct extensive co-design activities independently.

Despite growing evidence that digital technologies can support physical activity, reminiscence, and social connection among older adults, there remains a gap between older adults' lived experiences and the design priorities of digital technology developers, particularly SMEs. While participatory co-design can generate rich, contextual insights, resource constraints limit SMEs' ability to engage in sustained co-design processes. Consequently, there is a need for mechanisms that can translate rigorous co-design insights into forms that are accessible, practical, and usable within real-world development contexts, alongside empirical evaluation of whether such mechanisms meaningfully support development practice. This study seeks to address this gap.

One mechanism is the use of toolkits. In this context, a toolkit refers to a structured collection of guidance, recommendations, and examples intended to support developers in creating accessible, inclusive, and user-centered digital technologies. Toolkits offer a potential means of translating insights from rigorous co-design research into practical resources that can be applied within real-world development workflows. However, concerns have been raised that toolkits risk becoming tokenistic if they are not grounded in robust evidence or evaluated in applied settings. A review of 83 health-related toolkits found that only 31 (37%) had undergone any form of evaluation, and those that had were often assessed in artificial contexts with designers present, introducing potential bias [29]. The present study sought to address this.

Primary Objective

The primary objective of the Generating Older Active Lives Digitally (GOALD) project was to work with a diverse range of older adults to better understand their preferences and requirements in digital technologies aimed at increasing physical activity.

XSL•FO
RenderX

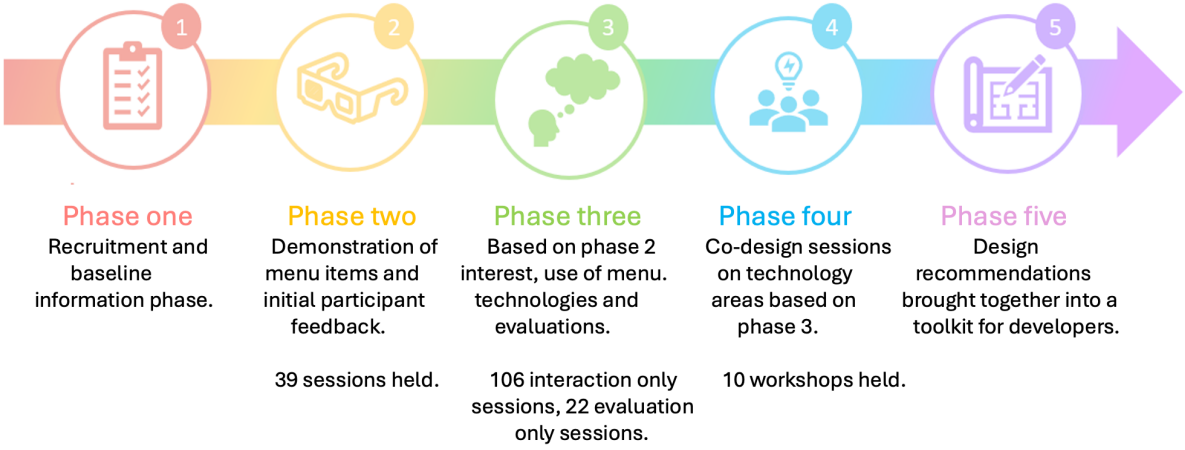
Secondary Objectives

Secondary objectives were (1) to use the recommendations emerging from working with older adults to co-design a toolkit for SMEs with a focus on digital physical activity, and (2) to evaluate the perceived usefulness of the toolkit with SMEs.

The primary contribution of this study is the development of a co-design–informed toolkit for SMEs, with the participatory process and implementation evaluation presented to support understanding of its development and perceived utility.

Methods

Ethical Considerations



This study received ethical approval from the Faculty of Health Ethics Committee at the University of Plymouth (project ID 3034, on November 29, 2021) and from the University of Stirling General University Ethics Committee (ref: 2021 2080 2106 on October 21, 2021). All participants provided written informed consent.

Study Design

The GOALD project, a collaborative project with the aim of exploring how digital technologies can support older physically and socially active lives, was based in Plymouth (Southwest England) and Stirling (Central Scotland). Older adults were recruited via partner organizations at both sites, plus an advisory group to support the methodology. This study was split into a series of phases, as outlined in Figure 1. Phases 1 - 4 involved participatory in co-design aligning with our primary objective; co-design workshops were held between June 2022 and November 2023. Phase 5 consisted of toolkit development followed by a qualitative implementation evaluation of the toolkit with SMEs, corresponding to our two secondary objectives.

Table 1 presents an overview of the purpose of each phase and details of its impact on the final toolkit.

Figure 1. Flow diagram demonstrating the breakdown of phases of the GOALD (Generating Older Active Lives Digitally) project.

XSL•FO
RenderX

Table . Purpose, number of participants, data collected, analysis, and impact on toolkit formation outlined for each phase and by site.

Phase	Purpose	Participants and sessions	Data collected	Analysis	Output or role in toolkit
Phase 1	Exploratory engagement and recruitment	213 participants recruited across the two sites	N/A[a]	N/A	Informed recruitment and initial engagement
Phase 2	Exploratory engagement and familiarization with digital technologies	England: 14 sessions, 40 OAs[b], 4 YAs[c], 9 staff; Scotland: 14 sessions, 42 OAs, 0 YAs, 11 staff	Informal feedback, baseline discussions	Not formally analyzed	Exploratory: informed selection of technologies for evaluation
Phase 3	Evaluate experiences of interacting with selected technologies	England: 27 technology interaction sessions, 22 formal evaluation sessions 60 OAs, 5 YAs, 12 staff; Scotland: 50 technology interaction sessions (with evaluation[d]), 60 OAs, 2 YAs, 18 staff[d]	Field notes, audio recordings of interactions, focus group and interview transcripts of evaluations	Reflexive thematic analysis	Direct: identified user needs, barriers, and priorities (see the study by Tomaz et al [30])
Phase 4	Co-design and prioritization of features	England: 8 sessions 28 OAs, 1 YAs, 3 staff; Scotland: 4 sessions, 18 OAs, 2 YAs, 6 staff	Ranking cards, workshop artifacts, audio recordings	Thematic synthesis + descriptive ranking	Direct: generated prioritized recommendations for toolkit, additional needs identified
Phase 5	Apply and evaluate toolkit with SMEs[e]	SMEs (n=10)	Reports, interviews	Reflexive thematic analysis	Evaluation: perceived utility and impact of toolkit. Recommended changes from SMEs implemented to produce final toolkit

[a]N/A: not applicable.

[b]OA: older adult.

[c]YA: younger adult.

[d]In Scotland, the care homes needed or wanted a lot more support than community groups or homes or groups in England with some of the more complex technologies, so some sessions in phases 1, 2, and 3 are counted twice as they included an introduction and interaction, or an interaction with a formal evaluation.

[e]SME: small- and medium-sized enterprise.

Participants

Recruitment took place through direct invitation and facilitation from our partners (Active Stirling, Sports Heritage Scotland [now Memories Scotland], iSight Cornwall, Hearing Loss Cornwall, Devon and Cornwall South Asian Society, Nudge, Cornwall Rural Community Charity, Generations Working Together, and UK Active and Sporting Heritage) and local care homes. Consequently, 213 participants reflecting a diversity of age, disability, ethnicity, and location from 18 case sites initially consented to this project; participants are characterized in detail in Table 1 and elsewhere [30]. In brief, older participants' mean age was 78.9 (SD 14.0), but the sample also included care home staff and young people aged 16 - 25 years. Of the participating older adults who provided data, 63% (55/87) were living independently; 75% (65/87) reported a health condition that limited them physically, mentally, or socially, and most reported using some type of corrective or assistive aid—most commonly glasses, hearing aids, or mobility aids; and participants were based in urban and rural areas across Central Scotland and Southwest England. The overall GOALD project examined both physical activity and sports reminiscence, and some participants only engaged in one of these components.

This paper reports data collected from participants who engaged in at least one session of physical activity in phases 2 - 4, resulting in 157 participants from 15 case sites across Central Scotland and Southwest England. Older adult participants were included if they had the capacity to consent, understood English, were aged 65+ years, and were living in a residential care home or attending a community group. Other participants were included if they were staff assisting the older adults in the co-design workshops due to being care staff or running the community group, or if they were members of the research team. Younger people were recruited through the community groups or from local high schools engaging in sport leadership training and intergenerational work (which was a broader goal of the GOALD project reported elsewhere [31]). However, the older adults were the main source of co-design insights, and we report the participant breakdown below simply for transparency as to who was present during the sessions. There were 80 Central Scotland participants and 77 Southwest of England participants.

XSL•FO
RenderX

A total of 56 older adults were from 7 care homes and 65 older adults from 8 independent living community groups. From the staff recruited, 24 of them were care home staff with varying roles and 5 of them were facilitators from community groups. Due to recruitment difficulties, only 7 younger adults from the community were recruited in total (Table 1). Details of sites are available in Multimedia Appendix 1.

Selection of Technology

Initial technologies were identified through the research team's existing academic, clinical, and industry networks to enable rapid access to a diverse range of digital tools relevant to physical activity, reminiscence, and social connection in later life. As this study progressed, additional technologies were purposively identified and introduced. This was in response to older adults' feedback and expressed interests, to ensure that subsequent evaluations and co-design activities aligned with participant priorities. Collectively, the technologies spanned multiple domains and modalities, including online physical activity platforms, immersive VR experiences, and other interactive digital tools. The technologies included in this study were not intended to represent an exhaustive or systematically sampled set of digital interventions.

As a result, older adults could try up to 20 technologies at different stages of development aimed at increasing physical activity and reminiscence. These included online physical activity platforms, VR experiences, social connectivity apps, voice technologies, camera glasses, activity trackers, balance boards, tablet-based aqua-aerobics, and social robots. Due to geographical constraints, not all technologies were available to all participants. Table 2 presents the technologies selected by participants for interaction during this project, which informed the development of the GOALD toolkit.

XSL•FO
RenderX

Table . Technologies participants interacted with throughout this project.

Name	Descriptions
Digital heritage bundle	VR[a] experience created within the University of Plymouth, allowing users to explore heritage remotely. Users are immersed in both audio and visual media, with 3D printed models of artifacts available alongside the VR.
MOTUS VR experiences	Three devices: 1. Standing omnidirectional treadmill with VR headset that allows users to explore both 3D scanned heritage sights and computer-generated environments. 2. Seated treadmill where they can explore computer-generated environments, with incentives to encourage movement. 3. A static seated experience, where 360 videos are uploaded into the headset, allowing users to be immersed in footage. As part of the treadmill experiences, remote users can be connected within virtual environments and explore together regardless of distance.
Oceans Conservation Trust experience	A VR experience created by the National Marine Aquarium (Plymouth, United Kingdom) Ocean Conservation Trust. The experience includes 360-degree videos taken from dives within the aquarium's tanks. Marine artifacts are also included to provide tactile and educational components. This experience was delivered by the Ocean Conservation Trust team.
Oculus Store apps[b]	National Geographic Explore VR Oculus app[b]: this allows physical movements, such as kayaking and walking, to explore hard-to-reach places worldwide. Brink Traveler[b]: users can walk through and learn educational information about locations worldwide.
danceSing/ danceSing Care	Online physical platforms that provide on-demand fitness classes for a range of abilities, including yoga, Pilates, barre, and singing content. There is also a live session component, allowing users to interact with others and instructors.
Mature Movers	Online platform that supports users in finding exercises suited to their needs and provides classes for those aged over 60 years to promote physical activity independence for as long as possible. A mixture of both face-to-face and online classes.
Elder Gym[b]	Online platform that provides exercise classes for older adults, including strength, endurance, balance, and flexibility. Classes are held on a social media platform for live interactions.
Wheel power[b]	Online exercise platform with chair-based exercises suitable for those with reduced mobility or wheelchair users. Live classes, alongside on-demand content.
Goodboost	Waterproof tablet that provides water-based exercises for older adults through an avatar and written instructions.
RetroRehab	Exergaming product created by Goodboost. Online platform with interactive "arcade style" exercise games to encourage movement to improve coordination, balance, and daily activities, for example, sit-to-stand repetitions.
HUR Ltd.	Balance training platform with a display touchscreen that uses the person's movement to control avatars in a range of games to encourage pneumatic strength and balance training.
Body Boosting Bingo[b]	A game of bingo delivered by Age Scotland in which numbers are called, and for each of the possible numbers there is an associated movement to build strength or balance. The movements can be done seated or standing.

[a]VR: virtual reality.

[b]Technologies that were provided in evaluation and co-design workshops only and not the earlier "menu" phase.

Between phases 3 and 4, researchers reviewed participant evaluations and conducted a horizon scan of available technologies based on their requests. Google searches using the phrases "virtual reality to see places for older people" and "online physical activity platforms for older adults" were conducted, with the first 5 pages of results reviewed to identify technologies aligned with participant feedback. Based on availability and location, additional technologies (also shown in Table 2) were provided for participants to trial before phase 4 co-design workshops.

XSL•FO
RenderX

Data Collection

Data were collected across phases 3‐5 using multiple qualitative methods; earlier phases (phases 1‐2) focused on exploratory engagement and familiarization where participants were shown a general menu of technologies related to encouraging physical activity, reminiscence, social connectivity, and access to places and spaces. These phases did not generate formally analyzed data (Table 1).

Regarding phase 3, based on interest expressed in phase 2, researchers (LC, HB, RB, CBS, and SAT) attended community group sessions or visited care homes to support participants in interacting with the technologies. At Plymouth sites, all community participants received logins to access online physical activity platforms at home or during community sessions, and care-home activity leaders received logins to facilitate sessions at their convenience. At Central Scotland sites, sessions were facilitated in-person by researchers; some of these took place in the university laboratory or swimming pool. During phase 3, data included observational field notes recorded by researchers, audio recordings of participant comments, and whiteboard notes captured during group activities. Formal evaluation focus groups and semistructured interviews were conducted in person or online to explore perceived benefits, barriers, usability, and suitability of the technologies. These sessions were audio recorded and transcribed verbatim.

Regarding phase 4, co-design workshops were conducted to identify participant priorities for the technologies. Based on phase 3 findings, 3 co-design themes were addressed: (1) VR for older adults to support physical activity and access to places and spaces; (2) online physical activity platforms for older adults; and (3) general physical activity technologies for older adults. Participants were reminded of the technologies encountered during this project and completed two activities: ranking cards and idea generation.

For the ranking-card activity, researchers synthesized features raised during initial interactions and formal evaluations, categorized them (eg, usability and interaction type), and produced cards for prioritization. Participants ranked cards from low to high priority within assigned categories (one or two per group). Photographs of the ranked cards were taken to generate quantitative priority data. For the idea-generation activity, participants worked in groups to respond to the prompt: “If there were no limitations, what would you want from VR technologies, online physical activity platforms, or physical activity devices to motivate physical activity for older adults or intergenerational groups?” Drawing on Harrington et al [32], participants were encouraged to consider activity type, content, appearance, motivation, and practical considerations. Groups discussed, wrote, and drew ideas using large paper, pens, and sticky notes, then presented them to the wider group. This card-ranking approach was selected because it is widely used in co-design to identify together what is most important and help move beyond discussions to actionable decision-making [33]. It also provides a visible, tangible record of how decisions were reached [34]. During these phase 4 co-design workshops, data comprised audio recordings of group discussions and presentations, written and drawn artifacts produced during idea generation activities, and photographs of ranked cards generated during prioritization exercises. All recordings were transcribed verbatim.

Regarding phase 5, findings from phase 3 interaction and evaluation sessions and phase 4 activities were synthesized into preliminary toolkits to support SMEs designing technologies for older adults, with a focus on physical and cognitive activity. The toolkits were distributed to 22 UK-based software SMEs across 2 calls (July and September 2023). SMEs were invited to submit small projects to apply the toolkit recommendations to improve existing products or develop new ones; 10 SMEs were selected for funding by a panel of GOALD researchers. As a grant condition, funded SMEs provided a short end-of-project report (maximum 6 months) detailing achievements, toolkit use, challenges, observed or anticipated impact, and recommendations for improving the draft toolkits. Following receipt of the reports, researchers (LC, HB, CBS, and John Ritchie, PhD) conducted 30-minute video calls with representatives from the 10 funded SMEs to discuss their feedback in more depth, emphasizing that candid reflections were encouraged given that funding had already been awarded. One interview (Football Memories Scotland) was conducted face-to-face during a researcher visit. Phase 5 data therefore included written end-of-project reports submitted by participating SMEs and audio-recorded follow-up interviews exploring toolkit use, perceived influence on design decisions, and implementation challenges, which were transcribed verbatim.

Data Analysis

Qualitative Analysis

Transcriptions from phases 3 and 4 were analyzed using reflexive thematic analysis following procedures outlined by Braun and Clarke [35]. Researchers (LC, HB, CBS, and SAT) first familiarized themselves with the data through repeated reading of transcripts and field notes. Initial codes were then generated inductively across the dataset, capturing features relevant to older adults’ experiences, preferences, and priorities. Codes were subsequently reviewed and organized into candidate themes, which were refined through iterative discussion within the research team to ensure coherence, internal consistency, and distinction between themes. Themes were then defined and named, and illustrative data extracts were identified to support interpretation. Analyses were initially conducted separately at each site due to differences in data collection timelines. These were then compared across datasets and integrated through team discussion. Where themes were conceptually similar, they were merged into cross-cutting themes. Where differences arose, these were retained and discussed within the research team to preserve contextual variation and ensure that divergent perspectives informed the final interpretation and toolkit recommendations. Analysis was conducted reflexively, with themes treated as interpretative patterns developed through engagement with the data rather than as fixed or exhaustive representations. These themes and codes formed the recommendations and produced 4 preliminary toolkits, which focused on VR for physical activity and accessing places and spaces (Plymouth), online physical activity platforms

XSL•FO
RenderX

(Plymouth), general physical activity platforms including online platforms (Stirling), and a reminiscence-based toolkit (Plymouth initially, updated with input from Stirling data for the second funding call to technology SMEs).

Final reports and interviews from phase 5 challenge-fund software SMEs were thematically analyzed following the same reflexive approach. Researchers (LC, HB, and CBS) familiarized themselves with all texts before independently conducting inductive coding on sections of the data. Texts were then swapped to compare and agree on coding interpretations. Patterns in the codes were identified to create overarching themes, which were reviewed and finalized across all texts. These themes and codes were subsequently merged and refined to produce a single, consolidated toolkit combining data from both sites.

Exploratory Quantitative Analysis

Card-ranking results from phase 4 were calculated after rebalancing scores to account for variation in group size and number of groups per session, and results were banded into tertiles. These 3 bands indicated features ranked as higher or lower priority, with the middle band reflecting neutral importance. Scores were rebalanced by weighting each site's feature score by the number of contributing groups and participants per group, reducing the influence of single participants or small groups. Final feature scores were averaged, excluding zero votes where features were not ranked by a group.

Results

Overview

From the thematic analysis of older adults' data, 7 themes emerged: motivation, content, barriers, design/inclusivity considerations, potential audiences/suitability, acceptability of technology, and motivations to use. Table 3 summarizes the core themes that emerged across the qualitative analysis and provides an overview of the cross-cutting concepts that structure the results presented below.

These themes were separated into 3 sections for the preliminary toolkits, to ensure the information was categorized clearly for SMEs. The 3 sections were general recommendations for technology for older adults, recommendations specific to physical activity platforms (eg, websites, apps, and exergames), and VR recommendations for those working in immersive technologies. Several themes crossed over different subsections; themes and codes (recommendations) are summarized below.

Table . Overview of the major themes that emerged across the qualitative analysis.

Major theme	What it captures
Motivation	Factors encouraging engagement, enjoyment, and sustained use
Barriers	Physical, psychological, and contextual challenges to uptake
Design and inclusivity	Hardware, software, and interaction features enabling accessibility
Content	Preferred types, qualities, and relevance of experiences
Acceptability	Comfort, trust, perceived value, and social acceptability
Suitability and context	Appropriate settings, user groups, and use conditions
Motivations to use	Perceived benefits (eg, well-being, social connection, activity)

General Recommendations for Technology for Older Adults

Themes and related codes that produced the recommendations for general technology for older adults and the evidence (quotes from participants) supporting the development of these themes are shown in Multimedia Appendix 2. Themes within this section included motivation, content, barriers, design, and inclusivity considerations. Recommendations covered suggestions from users on how to make the products motivating to use, from providing social components to incorporating gamification principles. General content suggestions included intensity of exercises, including relatable content, and that having variety and choice were key. Participants discussed barriers such as concerns regarding injury and how accessible the technology was. Finally, the theme of design or inclusivity considerations emerged, which included software considerations, such as using websites or apps, ensuring there are physical adaptations to the technology to make it easier for older adults to use, and seeking to understand what is "easy" for their target audiences to use.

Recommendations Specific to Physical Activity Platforms

Themes and codes that were specific to physical activity platforms and supporting evidence are presented in Multimedia Appendix 3. The main themes that were specific to physical activity platforms included motivation, design or inclusivity considerations, barriers, and potential audiences or suitability. To encourage motivation in users, physical activity platforms should have engaging instructors who are relatable to their audience, such as using older adult instructors. Live sessions were also highlighted as a motivation for users, as these allowed for social interaction components. Barriers included motivating users through a screen, when many preferred going outside or engaging in face-to-face classes, and if there were live classes, a preference was for these to be away from social media platforms. Design and inclusivity considerations included having clear visual follow-along, clear instructions, and having the ability to view on large screens. Potential audiences the older adults felt these platforms would be suited to included care home residents, community groups, people living alongside those less able or independent, and those living without access

XSL•FO
RenderX

to the outdoors. More detail on recommendations specific to physical activity technologies is reported elsewhere [30].

Recommendations Specific to VR Technologies

Of the main themes, 6 were linked to VR-specific recommendations and are presented in Multimedia Appendix 4. Older adults expressed praise for the technology and enjoyed the experiences and felt safe. However, they highlighted the need for consideration of how the technology is introduced to older adults and to consider generational differences with technology use. Barriers included older adults' attitudes to the technology and expectations such as fear of enclosed spaces and the need to consider balance and coordination when using VR technologies, alongside potential mobility challenges that impact older adults. Older adults wanted content not to be repetitive, and to avoid infantilization or child-like games. Content should be smooth, and any movements controlled. They did express concerns around addiction to technology, as well as concerns around confusion, disconnection between senses, and disorientation. Alongside psychological effects, there were concerns of physical effects such as body aches or health and safety concerns around falling or epilepsy. Older adults reported the technology must offer more than what is already available on other technologies.

Design considerations included the hardware used, such as using comfortable headsets but needing to factor in hygiene of the equipment and storage restrictions of locations. Software should include clear tutorials and guidance, have easy navigation between content, have clear and effective audio, simplified setup, and have consistent and reliable technology. Older adults raised having gamification, motivational rewards such as milestones and checkpoints within the virtual environments to encourage continued use. They also wished to be able to interact with the scenery and have movement as an option to explore, such as walking, skiing, seated movements, natural movements, rowing, and more. However, participants reported avoiding using teleportation movement in VR or any movement that results in a disconnect between senses. Participants suggested the ability to project content onto larger screens so that it becomes a group activity for more people to enjoy and facilitate communication.

Content suggestions included nature such as gardens, animals, coastal content, and under the sea. Historical content was also requested, including wonders of the world, archaeology, National Trust sites, museums, and archive footage. A range of activities were raised, such as experience sports, journeys on different modes of transport, shopping, visiting new locations, guided tours, and wanting a mix of passive and active experiences. Alongside this, there was a desire for personal content that could link them to familiar places or past holidays. Overall, older adults wanted longer content, colorful scenery with soothing audio, realistic imagery with details, audio guides, educational content, and most importantly, variety.

Older adults reported various perceived benefits that motivated them to use VR devices. One motivation to use VR was the enhanced experiences it could offer, such as giving access to places that older adults cannot access, whether due to mobility, cost, or mental health challenges, or activities that would otherwise be unsafe. VR offered them the opportunity for new experiences and to see new places, as well as providing an educational angle. As well as new experiences, the devices could be used to escape reality or relive old memories, so it would provide mental and physical stimulation. The physical motivations were the ability for it to facilitate exercise and provide interesting and distracting content while doing so, and identified the ability for it to have therapeutic uses. Older adults expressed the fun and enjoyment they had from using VR, and that it had potential to offer a social experience.

They felt that VR technology that increased physical activity and gave access to places and spaces was suitable for care home residents, people who needed more exercise, those with mobility issues, or those experiencing pain. It was highlighted that the technology could be suited to those who require rehabilitation, or those who are hospitalized or bed bound.

End-User Priorities for Technology SMEs From Rankings

Results from the exploratory ranking analysis in the co-design workshops where participants ranked their priorities for development are presented in Tables 4 and 5. These rankings should be interpreted as indicative outputs of workshop-based prioritization rather than generalizable or statistically robust measures.

XSL•FO
RenderX

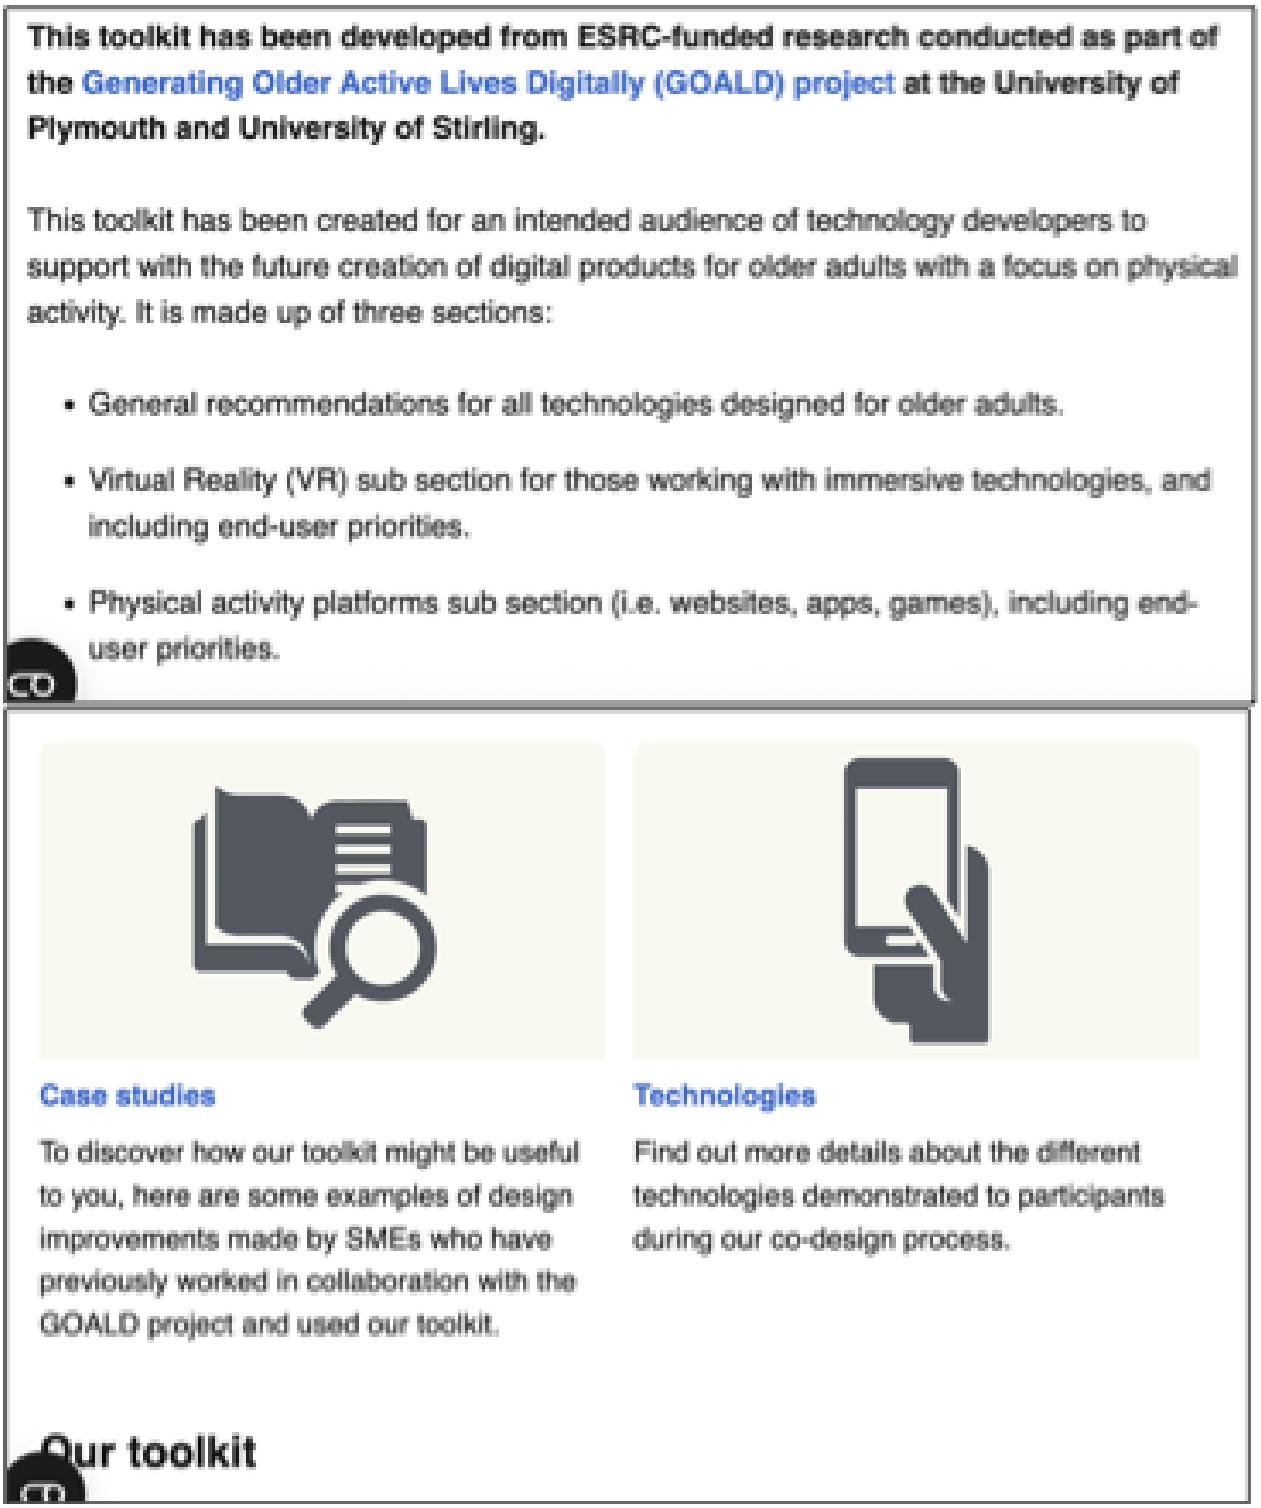
Table . End-user priorities ranked for physical activity platforms for older adults.

Priority level	Components
High priority	Follow-along videos, community of users (hosted in the platform), group activity in-person, visual follow-on, variety of content, live sessions, filter function on difficulty level, content for range of abilities, variety of songs to move to, assessment on suitable exercises, voice assistive technology, game scenario—reaching, stretching, moving, armchair activities, warm up and cool down activity, easy to navigate, ability to pause and come back, value for money (affordable), motivation to exercise, easy to use, easy to search, audio instructions (sight impairment), easy initial setup (sight impairment)
Medium priority	Gamified component—collecting badges, easy screen casting options, indoor cycling, varied cultural content, separate from social media platforms, audio description to navigate platform (sight impairment), gradual increase in intensity, individual activity, social forum component, yoga, music content for varied generations, someone to check your exercises, family activity, adjustable pace of sessions, adaptable video and font sizing, older tutors to match audience, big screen or not a mobile app, appropriate length (<45 min), translation options, closed captioning, frequent updates, space needed for activities, clear audio (speaking over music), dancing, group activity, range of video lengths
Low priority	Tutorial to navigate platform, extreme sports (skiing), reminders to take part (notifications), needs to be different from what is already received for free

XSL•FO
RenderX

Table . End user priorities ranked for VR[a] technologies for older adults.

Priority level	Components
High priority	Pedaling, people watching, guided tour, audio from the scenes filmed, different eras, varied content, multisensory (artifacts to hold, breeze to feel, and sand at beach), simple setup, historical information on audio, armchair exercise, information on what you are viewing, relaxing visual content, colorful, bright, interaction with objects, clear instructions on how to use, natural foot movements (walking not shuffling), places with memories, safety features on exercise equipment, comfortable headsets, natural movements, places usually expensive to visit, movement with feet, ability to move around in virtual environment, headset not too heavy, new experiences, not colorless, places no longer physically accessible, realistic, affordable price, detailed visuals (fine details, eg, leaves on trees and petals), cleanable, not simplistic models, high image quality
Medium priority	Rewards (incentives to continue [seeing something new or exciting]), show you locations you may have to go (reduce anxiety hospital appointments and shopping trips), pretravel knowledge (view where you will go), group activity on a big screen displaying VR content, POV[b] adrenaline experiences (zip lining, roller coasters, and horse riding), not cartoonish, physical activity associated with hobbies, that is, gardening, audio, sounds, or music (eg, blue planet), watch animals, sports matches, social element should be optional, seated movements (technology allows seated interaction), passive watching of nature, archeology, inclusive (mobility), related to hobbies, local places, dancing, family interaction, warnings on content (small spaces, heights, sit down, or dizziness), pedals to move around, menu self-orientates in front of you, outdoors, seaside, flowers, heritage sites, movement with hands, haptic feedback technology (gloves), historical events (jubilee or reminiscence), step counter, walking, stable movements (smooth and not teleporting), has to offer more than television, feel control over moving, subtitles (for hearing impairment), headphones for sounds, easy to put on headset, different countries, written cues to sound (for hearing impairment), concerts, interesting content, nature, countryside, educational aspect, paddling or rowing, audio journey or description (for sight impairment)
Low priority	Shopping trips (malls, in stores you no longer go to), treasure hunt (items to find), garden centers, races, social VR world, transferable or portable, peaceful places, busy environments (more hustle and bustle), competitions (including with family or grandchildren), races, audible directions of where to go (sight impairment), avatar customizable, historical information plaques, calm sounds, directional seated movement



[a]VR: virtual reality.

[b]POV: point of view.

Features were separated into 3 priority categories based on clustering the features according to calculated priorities to offer SMEs guidance on which features to prioritize in their product developments. The priorities were calculated by balancing the ranking across the venues, workshops, and group sizes to equal out scores from individuals over scores from groups. These were provided to the SMEs who won the challenge fund competition alongside the preliminary toolkits. The full GOALD toolkit is available online [36]. Screenshots illustrating the toolkit are shown in Figure 2.

XSL•FO
RenderX

Figure 2. Screenshots of the toolkit to exemplify its contents. ESRC: Economic and Social Research Council; GOALD: Generating Older Active Lives Digitally; SME: small- and medium-sized enterprise; VR: virtual reality.

With the support of the £5000 grants (a currency exchange rate of £1=US $1.23 was applicable) and use of the toolkits, 10 SMEs (Multimedia Appendix 5) were each awarded £5000 based on their ideas to use the preliminary toolkits and the likely impact of the product. They made meaningful adaptations to their products, enhancing accessibility, user experience, and engagement. Changes included merging platforms for better navigation, adding customization and accessibility features such as subtitles, creating instructional guides and videos, integrating physical activity trackers, improving content variety, and developing voice-based and intergenerational features. Several SMEs also introduced new software modules, games, and apps, addressed safety and inclusivity, and tailored content to better suit the needs and preferences of diverse user groups (Table 6). Physical activity-specific adaptations are considered and reported elsewhere [15,16,30].

XSL•FO
RenderX

Table . Adaptations made to products as a result of the challenge fund and toolkits.

Business	Adaptations with challenge fund
Mature Movers	Updated content to have varied workout duration and more variety, took into consideration instructor preferences, added sections and filters, and began the process of exploring recommended exercises.
Triangular Pixels	Added physical activity tracker into virtual reality game for feedback and motivation.
Sentai	Added intergenerational connectivity and reminiscence feature and added voice-based physical activity encouragement.
MOTUS Ltd	Improved set-up procedures and created instructional videos to reduce reliance on the MOTUS staff facilitating sessions.
danceSing	Merged 2 websites into a single platform, added more intuitive navigation, added more user customization options, added accessibility features, for example, subtitles, added instructional guides on using the platform, moved live sessions to the website instead of social media, added a user chat function, added content filters, added analytics on user engagement, used age-relatable instructors.
Age Scotland	Enhanced accessibility features, added subtitles, improved warm-up and cool-down videos, added relatable music and older models, added direction on breathing and posture, explored ways of supporting with safety, added software for alternative languages, added different intensities of exercises.
Good Boost	Included new games into the retro-rehabilitation game that focus on strength, balance, and coordination, developed aquatic resistance exercise equipment to help with strength.
HiCarer	Built a module within the app to support people in finding virtual physical activities and added filters for the content, added activities with music and seated movements based on toolkit recommendations.
Weekday Wow Factor	Created Amazon Alexa voice app to provide people with information on group activities, addressed accessibility concerns, made the app multimodal (audio and visual prompts).
Football Memories Scotland	Created audio and visual content for reminiscence and mental activity.

Themes From Analysis of SME Toolkit Users' Reports and Interviews

From the SME reports and interviews, 6 themes emerged. There were 4 themes related to the impact of using the toolkits on their own product development: adaptations, business benefit, enhanced end-user insight, and challenges to development. The SMEs were also asked for feedback on the toolkits themselves so the final version of the toolkit could integrate their feedback. Themes relating to the toolkit and its further development were aspects of the toolkit positively received, and improvements to the toolkit.

SMEs used the toolkits' suggestions to adapt their products, such as training older adults as instructors, improving exercise delivery, offering varied workout lengths, adding website filters for easier navigation, and simplifying VR setups. They also introduced activity trackers, new delivery platforms (eg, Alexa widgets), and AI-voice features to motivate users. Respondents said the toolkits provided valuable context and helped develop their ideas further. The SMEs reported business benefits, that using the toolkits boosted their credibility, confidence, and speed in making user-focused design decisions. It was especially valuable for early-stage product development, helping expand their audience and market potential. SMEs noted increased enthusiasm, higher product engagement, and reduced support needs due to usability improvements. Economic benefits included easier sales, increased or projected increased sales, lower operational costs, and higher product uptake. The toolkit also supported investment by showing alignment with user needs, and the GOALD challenge fund helped accelerate funding and product changes.

The toolkits provided valuable, enhanced end-user insights, helping SMEs adjust priorities, validate decisions, and inspire new product ideas while avoiding poor design. It increased their audience awareness and highlighted the importance of co-design, encouraging further user involvement. SMEs saw the toolkits as a lasting resource they could keep using and expanding with their own findings. SMEs also reported challenges including development costs, limited funding aligned with older adults' needs, and difficulties in conducting research and measuring impact. They also faced obstacles integrating into certain settings, accessing community facilities, and managing time constraints or technical delays.

Regarding the toolkits themselves, the positive feedback theme highlighted the ranking features for helping prioritize developments, supported by the broad recommendations. Overall, SMEs reported finding the toolkit simple, concise, and easy to follow with clear step-by-step guidance. They suggested improving the toolkit by adding more guidance on co-design research, explaining the recommendations' background, merging

XSL•FO
RenderX

toolkits to reduce repetition, adding visuals, hosting it online, and including interactive features such as checklists and case studies. They also recommended showing participants a wider range of technologies to avoid bias. Some SMEs felt the toolkit's usefulness varied depending on the developer's experience and stage in their journey. To illustrate the utility of the toolkits, quotes illustrating themes and codes are presented in Multimedia Appendices 6 and 7.

Discussion

Principal Findings

This study primarily reports the development of a co-design–informed toolkit for SMEs, supported by a participatory process and qualitative evaluation of its perceived utility.

The GOALD project engaged older and younger adults in intergenerational co-design to produce recommendations for developers, particularly SMEs, designing technologies for older adults, with a focus on increasing physical activity and reminiscence. This process resulted in a final toolkit providing developers with insight into older adults' priorities. Consistent with previous research, older adults perceived benefits of digital health technologies for healthy aging, including physical activity, and identified diverse potential deployment settings [16]. Challenges using some technologies independently or within care settings reinforced the importance of co-designing accessible technologies [18]. Despite these challenges, familiarization enabled older adults to provide usability solutions. Preliminary toolkits and evaluations suggested that this approach could help software developers, particularly SMEs, by reducing the time and cost of considering older adults' needs, while supporting conversations with investors.

Older adults engaged in using the technologies and evaluating them. The benefits of familiarizing themselves with the technologies to guide their suggestions in the final co-design workshops were evident in the abundance of suggestions provided by participants, as others have demonstrated [32]. Interest was, however, uneven across technology types, resulting in the toolkit focusing primarily on VR and online physical activity platforms. To increase applicability, a general technology recommendation section was included to capture codes relevant across multiple technology types. Although exposure to all possible technologies was not feasible, the toolkit is designed to be updated as new co-design research and technologies emerge.

This study suggests that older adults can successfully engage in co-design workshops; however, it was important to adapt to their needs and preferences to ensure they were able to fully participate in the sessions. This included providing technologies and researcher support to connect to online sessions, such as large screens and microphones to assist with hearing. Others have highlighted how not adapting to the older person's needs can result in resistance to participate in co-design and a loss of the credibility surrounding co-design [37]. Therefore, the GOALD project worked with an advisory group to guide the design of the current project and, during workshops, gave longer allocated time for sessions, moved closer to support with hearing, and built rapport with the participants to adapt to their requirements. Many participants became familiar enough with VR headsets to suggest content, often focused on reminiscence, supporting the value of such content for well-being [30]. VR SMEs may particularly benefit from the GOALD toolkit for future older adult projects.

Addressing prior research limitations, which focused on older adults with higher income, education, and digital competence [38], GOALD recruited participants from diverse backgrounds, including care home residents and independently living older adults with physical, visual, and hearing impairments. Recruitment of younger adults for intergenerational co-design was more limited, due to COVID-19 and scheduling conflicts, despite evidence of mutual benefits such as improved attitudes toward older adults and increased community connectedness [39]. Future research should emphasize and communicate these benefits to younger participants.

Dissemination of co-design findings often omits end users, reducing uptake of feedback [40]. GOALD's evaluation of the toolkit with SMEs indicated its perceived value in helping them address older adults' needs, with updated versions available [36]. Unlike previous guidelines for older adult technology design [41], which were generic, this toolkit offers specific, participant-informed guidance. Systematic reviews have noted the merits of older adult involvement in design but often lack evidence on real-world viability or acceptability of resulting technologies [42]. The present study contributes to addressing this gap in knowledge. Further, 4 of the 10 SMEs had not had their software or devices evaluated in our co-design workshops, suggesting transferability of the toolkit ideas beyond the products on which they were based. Many publications or toolkits offering guidance on software design are very "generic" such that software developers might have guessed the advice, for example, "easy navigation" and "good user interface." This research has produced guidance that is more specific, strengthened by examples from older participants and the target market. Previous co-design studies have used structured usability and acceptability evaluations to assess older adults' willingness to interact with specific technologies, such as social or assistive robots [43,44]. These studies typically focus on the feasibility, usability, or acceptability of a single system within a defined evaluation context. In contrast, this study adopted an upstream, design-focused approach aimed at generating transferable insights and recommendations across multiple digital technologies and real-world SME development contexts. These approaches are complementary, with structured usability and acceptability evaluation representing an important subsequent step following toolkit-informed design. This distinction highlights that toolkit-based approaches operate upstream in the design process, whereas usability and feasibility studies typically evaluate downstream implementation and user interaction.

While participating SMEs found the toolkit useful and were able to apply its recommendations, embedding it into routine development practices over the longer term remains challenging. Ongoing use is likely to depend on practical factors such as time, resources, competing priorities, staff changes, and the

stage of product development. These factors help explain why SMEs applied the toolkit selectively in this study and suggest that future evaluations should examine how well such resources fit within everyday SME development practices over time.

Future research should evaluate the toolkit prospectively by embedding it from the earliest stages of product or service development and following its use over longer timeframes. This study suggests that the toolkit informed both adaptations to existing products and the development of new features and services. However, a fully prospective "from inception" evaluation would enable assessment of how toolkit recommendations shape design decisions across the full development lifecycle and their downstream impact on end-user outcomes. Such studies would benefit from longer funding periods and closer integration with SME development cycles to support sustained implementation and evaluation.

Limitations

This study has several limitations. Feature priorities were ranked to indicate their relative importance to older adults; however, differing timelines across sites meant that features could not be merged into a single ranking exercise. This resulted in separate initial toolkits for England and Scotland. In addition, not all technologies were available at every site, and facilitation differed across settings, which may have influenced participants' experiences and priorities. These differences across settings are discussed in detail elsewhere [30].

The card ranking exercise used in phase 4 was intended as a pragmatic prioritization tool to support co-design rather than as a validated quantitative measure. Rankings were used to indicate relative importance of features within the workshop context, and although steps were taken to rebalance scores for variation in group size and participation, the approach remains exploratory and context-specific. As such, ranking outputs should be interpreted as indicative of older adults' priorities to inform toolkit development, rather than as definitive or statistically robust measures of importance across populations or contexts. Despite this, participating SMEs reported that the toolkits provided specific, practical guidance that could be directly implemented to update or adapt their products.

The evaluation of toolkit impact was, of course, based on self-reported feedback from participating SMEs rather than the direct measurement of downstream design processes or end-user outcomes. This approach was taken because this project's funding window and scope did not permit longitudinal follow-up or independent assessment of postimplementation outcomes within participating organizations. As such, findings reflect SMEs' perceived utility and influence of the toolkit on their decision-making, rather than objectively measured changes in product quality or user outcomes. Reported impacts may therefore be subject to social desirability or recall bias, although this risk is reduced by the fact that feedback was collected after funding had been awarded and toolkit use had occurred. In addition, adoption of the toolkit recommendations varied across organizations, reflecting differences in development stage, resources, and priorities. This heterogeneous and partial adoption limits generalizability but reflects realistic patterns of toolkit use within SME development contexts.

The provision of the small challenge funds was likely to have been a catalyst for the use and success of the toolkits, but this was a crucial first step in testing them as part of the GOALD project. Future research could assess the resulting impact on older adults of adaptations to technologies made based on the toolkits; this was beyond the scope of the present research. Finally, the toolkits were produced following the selection of a limited range of digital products focusing on keeping older adults active. Nevertheless, 2 of the 10 SMEs awarded funding were from other areas (HiCarer, a directory type application, and Sentai focusing on connecting people with friends and family), suggesting broader applicability of the recommendations.

Conclusions and Future Research

Involving older adults in the co-design of technologies to support healthy aging is important for developing technologies that are more likely to be acceptable and relevant to older adults.

The GOALD project engaged older adults in co-design for technologies to support healthy aging with a focus on aiming to increase physical activity and connectedness to produce the present toolkit. This study focused on upstream design and implementation processes rather than direct measurement of aging-related health or functional outcomes. However, the toolkit was intended to support age-appropriate design decisions that may influence downstream usability, engagement, and outcomes. Evaluation of health, functional, or behavioral impacts requires longer-term implementation and outcome-focused study designs and is therefore an important next step for future research. The toolkit may act as a knowledge exchange between the research with older adults and with current and future SMEs, to help facilitate continued developments and engagement with co-design. SMEs who tested the toolkit reported useful content which informed some of their product adaptations and was perceived to support some business benefits. Future research could consider evaluating the impact of toolkit-informed adaptations to technology on older adults. It could also incorporate the results of co-design work on a broader range of technologies designed to increase other activity beyond physical activity and reminiscence.

Acknowledgments

We thank the participants of the co-design workshops and the 10 small- and medium-sized enterprises (SMEs) who were funded by the Generating Older Active Lives Digitally (GOALD) "mini-challenge" fund. The support of UK Research and Innovation via the Healthy Ageing Social Behavioural and Design Research Programme (SBDRP; ES/V016113/1) from the Economic and Social Research Council (ESRC) is gratefully acknowledged. Generative AI was not used in this paper.

Funding

UK Research and Innovation provided funding via the Healthy Ageing Social Behavioural and Design Research Programme (SBDRP; ES/V016113/1) from the ESRC. Ten SMEs were funded by the GOALD "mini-challenge" fund. ESRC had no role in the conduct of this study.

Data Availability

Transcripts and researcher notes from focus groups have been archived with this project with the ESRC as per funding requirements and are available via the UK Data Service.

Whittaker, Faculty of Health Sciences & Sport, University of Stirling, (Core Management Team); Sheena Asthana, Plymouth Institute for Health and Care Research (PIHR), University of Plymouth; Rory Baxter, Faculty of Health, University of Plymouth; Hannah Bradwell, Faculty of Health, University of Plymouth; Arunangsu Chatterjee, Faculty of Medicine and Health, University of Leeds; Pete Coffee, School of Social Sciences, Heriot-Watt University; Leonie Cooper, Faculty of Health, University of Plymouth; Alison Dawson, Faculty of Social Sciences, University of Stirling; Katie Edwards, Faculty of Health, University of Plymouth; Swen Gaudl, Department of Applied IT, University of Gothenburg; Tanja Krizaj, Faculty of Health, University of Plymouth; Greg Mannion, Faculty of Social Sciences, University of Stirling; Gemma Ryde, Institute of Cardiovascular and Medical Sciences, University of Glasgow; Alejandro Veliz Reyes, Faculty of Arts, Humanities and Business, University of Plymouth; John Ritchie, Faculty of Arts & Humanities, University of Stirling; Colin B Shore, Faculty of Health Sciences & Sport, University of Stirling; Simone Tomaz, Faculty of Health Sciences & Sport, University of Stirling; Alison Warren, Faculty of Health, University of Plymouth; Karen Watchman, Faculty of Health Sciences & Sport, University of Stirling; Katharine Willis, Faculty of Arts, Humanities and Business, University of Plymouth; and partners: Active Stirling Ltd, Generations Working Together, Hearing Loss Cornwall, Nudge Community Builders, South Asian Society (Devon and Cornwall), Sporting Heritage, Sports Heritage Scotland, St. Breward Community, iSight Cornwall, and UKActive.

Conflicts of Interest

ACW declared an in-kind existing research relationship with danceSing working on a project independent of GOALD. None of the other authors have any competing interests in this study. None of the authors are on the editorial board of the journal or on any committee that may benefit from publication of this paper. There are no legal proceedings relevant to this study. No authors had any financial interest in the 10 companies that participated in this study during this study. ACW has since provided some consultancy to danceSing on a separate project from 2023 to 2024. The authors developed the "toolkits" that were evaluated in this study. These toolkits are freely available to all technology developers.

Abstract

Background: Older adults often express positive attitudes toward digital health technologies in surveys, yet adoption remains low. Self-report measures may not capture automatic affective reactions such as anxiety or distrust. Implicit paradigms such as the affect misattribution procedure (AMP) can reveal these automatic attitudes, but parameters optimized for younger adults may not be suitable for older adults because of age-related slowing and changes in visual processing.

Objective: This study aimed to adapt and evaluate an influence-aware affect misattribution procedure (IA-AMP) for measuring implicit attitudes of older adults toward digital health technologies and to identify an age-appropriate prime duration that balances affect transfer strength with minimal conscious awareness.

Methods: A 2-phase methodological adaptation and feasibility study was conducted among older adults (aged ≥60 y). Phase 1 (n=40) involved the development and validation of age-relevant synthetic images depicting older adults using digital health tools. The images were evaluated based on valence, arousal, thematic relevance, and low-level perceptual features. Phase 2 (n=56) implemented an IA-AMP with 3 prime durations (75, 350, and 425 ms) across 2 sequential cohorts. The first cohort (batch 2A, n=29) used the initial awareness probe, whereas the second cohort (batch 2B, n=27) used a simplified awareness interface. The core IA-AMP target judgment task remained unchanged across batches. The primary inferential outcome was the binary trial-level target judgment, coded as pleasant or unpleasant. Trial-level responses were analyzed using binomial logistic mixed-effects models with prime valence, prime duration, their interaction, and batch as fixed effects, along with random intercepts for participant and prime image. Awareness analyses were restricted to batch 2B.

Results: The primary generalized linear mixed-effects model showed a significant prime valence × prime duration interaction (χ^2_2=38.1; *P*<.001). Positive primes increased the odds of pleasant target judgments relative to negative primes at all durations (odds ratio [OR] 11.2, 95% CI 5.8-21.6, at 75 ms; OR 31.9, 95% CI 16.0-63.4, at 350 ms; and OR 45.6, 95% CI 22.1-94.0, at 425 ms; all Holm-adjusted *P*<.001). The positive-negative contrast was smaller at 75 milliseconds than at 350 and 425 milliseconds, whereas the contrasts at 350 and 425 milliseconds did not differ significantly. Batch sensitivity analyses showed stronger overall priming in batch 2B, but the prime valence × prime duration × batch interaction was not significant (χ^2_2=0.76; *P*=.68).

Conclusions: The IA-AMP offers a promising approach for assessing the affective responses of older adults to digital health technologies beyond self-report. A prime duration of approximately 350 milliseconds appears to be a practical calibration point for AMP studies involving older adults, producing strong affect transfer effects while avoiding the longest exposure duration.

XSL•FO
RenderX

Because reported influence awareness was common, AMP effects should be interpreted alongside awareness measures rather than as awareness-free implicit attitudes. AMP-based affective measures may complement usability and adoption research by identifying emotional responses that users may not readily articulate, thereby supporting more inclusive and evidence-informed development, evaluation, and implementation of digital health technologies for aging populations.

KEYWORDS

older adults; digital health; technology adoption; implicit attitudes; affect misattribution procedure; usability; behavioral science

Introduction

Background

As global populations age, maintaining health, independence, and quality of life for older adults has become a public health priority. Digital health technologies, such as telemedicine platforms, wearable sensors, and smart home monitoring systems, are increasingly used to support older adults in managing chronic conditions and maintaining independence while aging in place. These tools can enhance health outcomes, reduce hospitalizations, and promote independent living by extending clinical monitoring into the home environment and supporting self-management [1,2]. However, despite these benefits, adoption remains limited. Many older adults report anxiety, low confidence, and mistrust toward digital tools, reducing engagement even when access and technical support are available [3]. Understanding both conscious and automatic emotional reactions to these technologies is crucial because affective comfort and trust often predict sustained use and adherence to digital health programs.

Most research on technology adoption of older adults relies on self-report measures. However, older adults may provide overly positive responses due to social desirability or limited self-awareness of their emotional responses. As a result, surveys may underestimate discomfort or resistance toward digital health tools [4]. Complementary assessment approaches are therefore needed to uncover emotional barriers that older adults may not express directly. Implicit measures offer one such approach by indexing automatic affective responses that operate outside conscious awareness and sometimes predict behavior beyond explicit reports [5,6]. By capturing intuitive reactions rather than deliberate opinions, these measures can reveal how well a technology truly aligns with users' needs and sense of security.

Implicit Attitudes and Measurement Gaps

Implicit attitudes, defined as automatic positive or negative reactions that occur outside conscious awareness [5], can shape real-world behavior, including technology use. Measuring these implicit responses can reveal how older adults actually feel about digital health technologies, even when they cannot or do not verbalize these attitudes. The affect misattribution procedure (AMP) is a validated tool for capturing such automatic affect transfer [7]. In this task, participants rate neutral stimuli that are briefly preceded by an affective "prime" (eg, an image of a health device), and the prime's emotional valence tends to bias evaluations of the neutral target. This paradigm has been used to study implicit evaluations of political and social stimuli [8,9], but its application to digital health contexts and older populations remains limited.

The AMP has been widely used in studies involving younger adults [7] but has rarely been tested in older populations or with age-relevant digital health imagery. Age-related differences in processing speed and attention suggest that standard AMP settings (approximately 75-ms primes) may be suboptimal for older adults, as slightly longer exposures may improve perceptual registration while also increasing the likelihood of conscious awareness [10,11]. Moreover, ecological validity matters in later life. Older adults may process age-congruent faces differently from younger faces, which highlights the importance of age-relevant materials when assessing affect [12]. Therefore, using stimuli that depict older adults in familiar health technology scenarios may produce more meaningful and representative affective responses.

Current Knowledge Gap

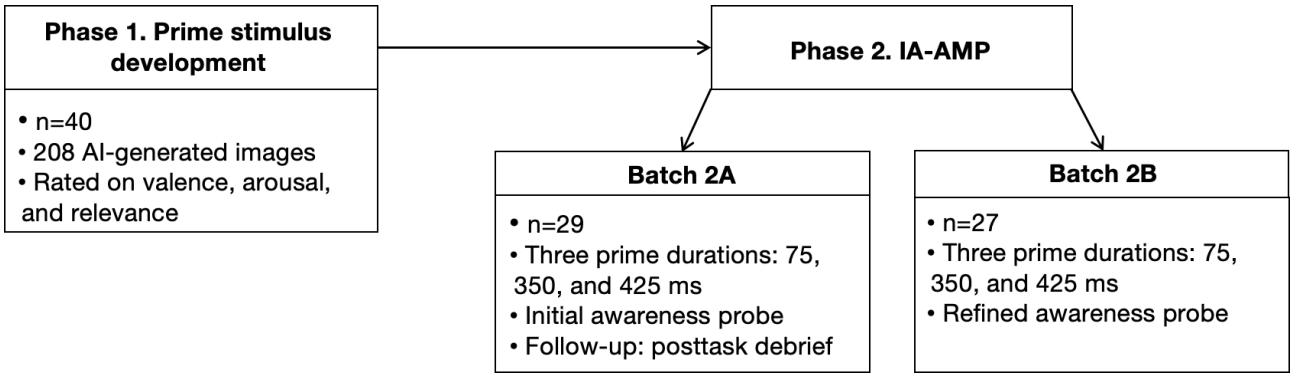
Prior work also indicates that awareness of primes can modulate AMP outcomes, although the direction and interpretation of this modulation remain debated [7]. Some findings suggest that conscious awareness amplifies affect transfer [13], whereas others view awareness reports as post hoc interpretations of implicit responses [14]. For aging research, the practical challenge is to measure automatic affective responses to digital health cues while minimizing demand characteristics and undue reliance on self-reported awareness [7]. To address this gap, there is a need to adapt implicit attitude paradigms so that they remain both sensitive and truly implicit when used with older adults. Determining timing parameters that maximize affect transfer while minimizing awareness may help clarify how best to assess older adults' spontaneous emotional reactions to digital health technologies.

Objective

This study tested whether the AMP can sensitively detect older adults' implicit attitudes toward digital health technologies and examined task parameters that optimize performance for this population. We conducted a 2-phase study with older adults recruited from a hospital setting to develop and validate age-relevant prime images depicting realistic digital health scenarios to ensure ecological validity and administer an AMP with 3 prime durations (75, 350, and 425 ms) and trial-level awareness assessments to evaluate whether affect transfer occurs, whether its magnitude varies by duration, and whether AMP effects persist on trials without reported awareness.

Our goal was to provide an age-appropriate, scalable, and health-relevant method to uncover unspoken comfort or

XSL•FO
RenderX



hesitation toward digital health tools so that designers and clinicians can better tailor user-centered interventions that support trust and engagement. By identifying optimal timing parameters for implicit attitude assessment in older adults, this work also contributes a new methodological resource for evaluating emotional readiness and acceptance of digital health technologies.

Methods

Study Design and Overview

We conducted a 2-phase methodological adaptation and feasibility study with older adults to examine whether AMP can capture implicit attitudes toward digital health technologies and to identify timing parameters appropriate for older participants. Phase 1 involved development and validation of age-relevant prime images depicting older adults in digital health contexts, evaluating perceptual balance and affective clarity. Phase 2 was conducted across 2 sequential cohorts: batch 2A and batch 2B. Both cohorts completed the same core influence-aware affect misattribution procedure (IA-AMP) target judgment task, in which participants evaluated ambiguous target images as pleasant or unpleasant after positive or negative digital health primes or gray-square baseline trials. Batch 2A used the initial awareness-probe interface. Because no awareness responses were recorded in batch 2A despite explicit instructions, participant debriefings were used to refine the awareness-probe interface for batch 2B. The batch 2B procedure simplified the awareness response but retained the same core IA-AMP target judgment task. Therefore, both cohorts were included in the primary AMP analysis, whereas awareness-related inference was restricted to batch 2B. All procedures were conducted in Mandarin. Figure 1 illustrates the overall study flow.

Figure 1. The overall study flow. IA-AMP: influence-aware affect misattribution procedure.

Ethical Considerations

Both studies were approved by the Ethics Committee of the School of Public Health, Zhejiang University (approval ID ZGL202411-1). All participants provided written informed consent before participation. Prime stimuli were synthetically generated to avoid any identifiable human participants; no personal data were collected or stored.

Setting, Eligibility, and Recruitment

Participants aged ≥60 years were recruited from an inpatient geriatric department of a hospital in Hangzhou, China. Testing was conducted individually in a quiet, well-lit room using a standard desktop computer with a full keyboard. Inclusion criteria included normal or corrected-to-normal vision and the ability to understand and perform computerized tasks. Exclusion criteria included visual impairment, a history of neurological or psychiatric conditions (eg, stroke, dementia, Parkinson disease, and major depression), use of medications with cognitive side effects, motor impairments preventing keyboard use, or noncompliance during practice (eg, pressing the same response key on all trials).

Phase 1: Stimulus Development and Validation

Objective

The first phase aimed to create a perceptually balanced, age-relevant set of positive and negative digital health primes and verify affective clarity and thematic relevance for older adults.

Stimulus Generation and Screening

A pool of 208 AI-generated images depicting older adults engaging with digital health technologies was created using Imagen 3 (Google). Prompts systematically varied 3 content dimensions: older-adult descriptors (eg, “senior” and “retired individual”), digital health contexts (eg, telemedicine, wearable sensors, and health apps), and emotional expressions (eg, happy, satisfied, frustrated, concerned, and neutral). All images were synthetic and were pilot-screened by 3 independent researchers for realism, clarity of emotional expression, cultural appropriateness, and absence of identifiable or sensitive content before inclusion in the task.

Perceptual Control and Preselection

To minimize low-level visual confounds, all images were processed in Python (OpenCV) to extract spatial frequency (2D Fourier transform on grayscale), chromatic complexity (color entropy in HSV), and luminance (mean intensity of 0 - 255). Feature values were *z*-standardized, and Euclidean distance from the global centroid (0, 0, 0) was calculated to quantify perceptual deviation. We retained 25 images per valence category (positive, neutral, and negative; N=75) with the smallest distances for the behavioral rating phase.

XSL•FO
RenderX

Participants

A total of 40 older adults completed the rating task (2 additional participants were excluded due to noncompliance). Demographic information is summarized in Table 1.

Table . Demographic characteristics (study 1, n=40).

Variable	Value
Age (y), mean (SD)	68 (6.25)
Gender: female, n (%)	19 (47.5)
Education, n (%)

DHT[a] users, n (%)	30 (75)

[a]DHT: digital health technology.

Procedure

After 10 practice trials, each participant viewed the 75 preselected images once in randomized order (500 × 400 pixels). To prevent cross-dimensional interference, participants were randomly assigned to rate either valence or arousal (7-point scale); all participants also rated relevance (7-point scale) to the theme "older adults using digital health." Standardized instructions in Mandarin were presented onscreen and reiterated verbally. Responses were recorded by mouse click, and the task advanced automatically to the next trial.

Outcome Measures and Data Analysis

For each image, we computed mean ratings of valence, arousal, and relevance. Interrater reliability was estimated using the intraclass correlation coefficient (ICC[2,k]). Images were retained if they met predefined thresholds: valence≥5 (positive), ≤3 (negative), or 3.5 to 4.5 (neutral); relevance≥4; SD<1.5 for valence and relevance; and ICC≥0.70. Because neutral human images were not consistently rated as neutral, the neutral condition for the AMP task in phase 2 was operationalized as uniform gray squares, serving as a perceptual baseline. Normality was assessed using Shapiro-Wilk tests; group comparisons on perceptual features used ANOVAs or Kruskal-Wallis tests, as appropriate. Arousal was compared between final positive and negative sets to confirm matched emotional intensity. The final prime set comprised 5 positive and 5 negative age-relevant images matched in arousal and perceptual complexity.

Phase 2: IA-AMP (Duration Optimization and Awareness)

Objective

The second phase aimed to test whether the IA-AMP can capture older adults' implicit attitudes toward digital health technologies and to assess how variations in prime duration and awareness affect these responses.

Participants and Design

A total of 56 older adults participated across 2 sequential cohorts (Table 2). Batch 2A (n=29; mean age 65.0, SD 3.6 y; range 60 - 71 y) used the initial awareness-probe interface, which prompted participants for 5 seconds to press the "6" key if they felt influenced by the preceding prime; otherwise, they were instructed to press nothing. Following preliminary testing in batch 2A and participant debriefing, the awareness interface was simplified in batch 2B (n=27; mean age 67.3, SD 4.9 y; range 61 - 79 y) using a 4-second prompt requiring a space bar response. Batch 2A and batch 2B did not differ significantly in sex (P=.11) but differed modestly in age (P=.048) and substantially in education, with lower-education participants concentrated in batch 2A (P<.001).

The core AMP judgment task was unchanged across batches. Both batches used a 2 (prime valence: positive and negative) × 3 (prime duration: 75, 350, and 425 ms) within-participant design. Eligibility and ethics procedures mirrored phase 1.

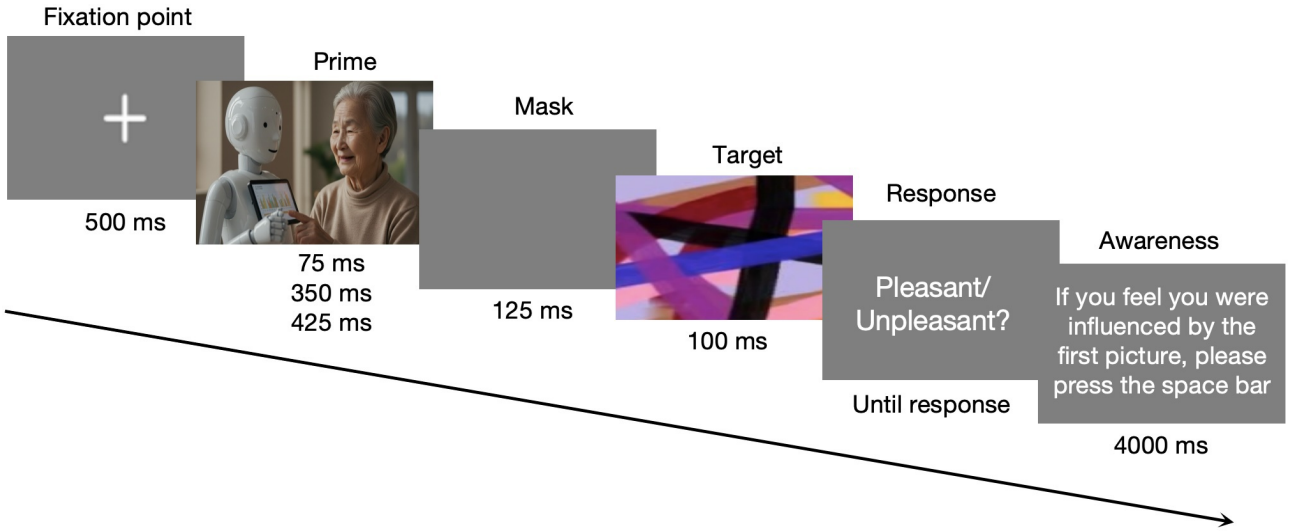
Materials and Apparatus

Five positive and 5 negative images from phase 1 were used as primes. Neutral primes were not carried forward because they were not consistently rated as neutral during phase 1. Instead, a uniform gray square was used as a perceptual baseline. The targets were 40 abstract paintings [15], which were chosen because these images are evaluatively ambiguous [16]. All stimuli were shown in PsychoPy (version 2023.2.1; Open Science Tools Ltd) on a 24-inch monitor (500 × 400 pixels). Participants used a standard keyboard to record their responses, and each trial ended with a blank screen that stayed visible until a key was pressed.



Procedure

Batch 2A

Each participant first completed 10 practice trials to become familiar with the task, followed by 90 critical trials divided into 6 blocks of 15 trials each. The trials included positive, negative, and gray-square baseline trials, and prime duration (75, 350, or 425 ms) was randomized within each block. On every trial, a fixation cross appeared for 500 milliseconds, followed by the prime image for the assigned duration. After a 125-millisecond blank screen, a target abstract painting was shown for 425 milliseconds. A black-and-white mask then remained on the screen until the participant responded. Participants pressed the “E” key if they judged the painting to be less pleasant than average and the “I” key if it was more pleasant than average. Immediately after each target evaluation, an awareness prompt appeared for 5 seconds with the instruction to press the “6” key if they felt that the preceding image had influenced their judgment; otherwise, they waited for the next trial. A 1-second interval separated trials. Participants were free to rest between blocks for as long as needed and could press the space bar to continue when ready. Primes were sampled randomly without replacement, and the order of trials was fully randomized so that the task proceeded in a fixed forward direction. The absence of awareness responses under this initial interface prompted posttask debriefings, which informed a simplified awareness-probe interface for batch 2B (Figure 2). The core IA-AMP target judgment task was unchanged.

XSL•FO
RenderX

Figure 2. Trial structure of the influence-aware affect misattribution procedure used in batch 2B. Batch 2A followed the same sequence but included a 5-second awareness prompt requiring a "6" key press and displayed the awareness screen after all trials, including gray-prime trials.

Posttask Probe

To supplement the trial-level awareness probe, 20 of the 29 participants were asked a brief set of follow-up questions immediately after completing the AMP task. These short probes were conducted in Mandarin by the researcher and focused on 4 domains: (1) task comprehension (eg, whether the instructions were clear), (2) interface usability (eg, ease of key presses and legibility of text), (3) cognitive load and fatigue (eg, whether the task felt confusing or tiring), and (4) perceptions of the awareness key (eg, whether participants understood what it meant).

Responses were grouped into 3 categories: (1) nonconscious processing, (2) procedural and interface-related barriers, and (3) motivational factors. These descriptive data were not analyzed as a full qualitative dataset but were used to contextualize the quantitative awareness results.

Batch 2B

Batch 2B used the same IA-AMP target judgment procedure as batch 2A, with a simplified awareness task based on batch 2A debriefings. Participants pressed the space bar instead of the "6" key to report awareness, and the awareness prompt appeared for 4 seconds. To reduce fatigue, the awareness screen was omitted during gray-square baseline trials. Therefore, awareness responses in batch 2B were collected only for positive-prime and negative-prime trials.

Data Analysis

Outcome Measures and Data Handling

The primary inferential outcome was the trial-level target evaluation in the IA-AMP task, coded as 1 for "pleasant" and 0 for "unpleasant." Consistent with standard AMP scoring, the AMP effect was summarized descriptively as the difference in the proportion of pleasant judgments following positive vs negative primes at each prime duration. "Pleasant judgments" refer to participants' evaluations of the ambiguous target paintings, whereas "positive" and "negative" refer to the valence of the preceding prime image. These proportions are reported only to illustrate the magnitude of the effect; formal statistical inference was performed at the trial level, as described in the *Statistical Analysis* section.

The primary positive-negative AMP analysis included only trials with the validated set of 10 affective primes, comprising 5 positive and 5 negative images. Gray-square baseline trials were excluded from this comparison because they served as perceptual baseline trials and did not contribute to the positive vs negative effect. Trial logs were checked for missing or duplicate responses and for noncompliance (eg, identical responses across all trials), and no missing or duplicate responses or instances of noncompliance were detected.

The secondary outcome was trial-level awareness response frequency among batch 2B trials that included an awareness prompt, indicating whether participants reported that the preceding prime influenced their judgment on a given trial. Awareness analyses were restricted to batch 2B because the awareness-probe interface differed between batches, and gray-square baseline trials were not included because they did not receive awareness prompts. Descriptive feedback from posttask interviews in batch 2A was used to contextualize awareness-probe comprehension and interface-use issues but was not included in inferential analyses.

Statistical Analysis

The binary trial-level outcome described above was analyzed using binomial logistic generalized linear mixed-effects models (GLMMs). The primary AMP model was fitted to the final positive-prime and negative-prime trials and included prime valence, prime duration, their interaction, and batch as fixed effects, with random intercepts for participant and prime image. The focal prime valence × prime duration interaction was evaluated using likelihood-ratio comparisons between models with and without the interaction. Duration-specific positive vs negative contrasts were estimated at each prime duration, with Holm correction applied across the 3 contrasts. Model diagnostics were evaluated using checks for model convergence, overdispersion, and residual patterns.

XSL•FO
RenderX

Positive vs negative prime contrasts were estimated at each prime duration. Because contrasts were examined at all 3 durations, *P* values were adjusted using the Holm method. Odds ratios (ORs) with 95% CIs were reported. Descriptive AMP scores, calculated as positive minus negative differences in pleasant-response proportions, were reported to aid interpretation but were not used as the primary inferential test. To evaluate whether the findings were robust to additional stimulus-level control, an item-control sensitivity model was fitted with crossed random intercepts for participants, prime images, and target images.

Trial-level awareness responses were analyzed in batch 2B only because the awareness-probe interface differed across batches. Awareness was modeled as a binary outcome, indicating whether participants reported that the preceding prime influenced their judgment on a given trial. Gray-square baseline trials were excluded because they did not receive awareness prompts.

To evaluate whether AMP effects differed across the 2 sequential cohorts, batch-interaction sensitivity models were fitted with batch and its interactions with prime valence and prime duration as fixed effects, along with random intercepts for participant and prime image. A targeted likelihood-ratio test compared a model with all 2-way batch interactions to a model that additionally included the prime valence × prime duration × batch interaction. To assess whether differences in cohort composition accounted for the priming effect, the primary model was additionally refitted with participant age, sex, and education as covariates.

All analyses were conducted in R (version 4.5.3; R Foundation for Statistical Computing). Binomial logistic GLMMs were fitted using glmmTMB. Estimated marginal means, model-estimated probabilities, and duration-specific contrasts were obtained using emmeans, with Holm correction applied across the 3 contrasts. The focal prime valence × prime duration interaction was evaluated using a likelihood-ratio test comparing models with and without the interaction term. Model diagnostics were assessed using DHARMa.

Results

Phase 1: Stimulus Validation

Participant Characteristics

A total of 40 older adults (aged 60 - 87 y; mean 68, SD 6.25 y; n=19, 47.5% female participants) completed the image-rating task. Two participants were excluded due to noncompliance (identical responses across trials). All remaining participants met the inclusion criteria and had normal or corrected vision.

Perceptual Feature Analysis

To evaluate whether the AI-generated images were perceptually balanced, we compared low-level visual properties (spatial frequency, chromatic complexity, and luminosity) across the 3 valence groups (Table 3).

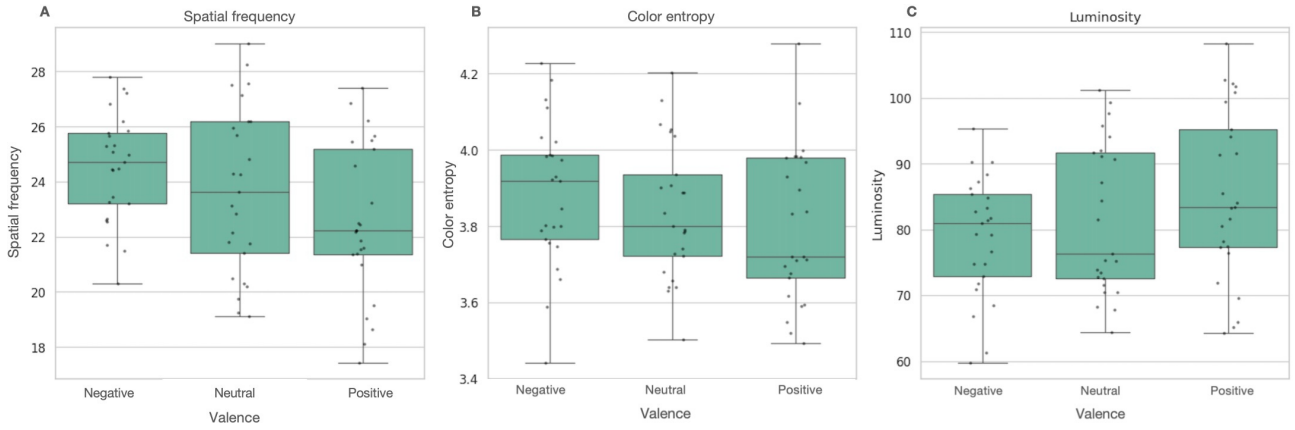


Table . Means and SDs of perceptual features for AI-generated images by valence category (N=75).

Valence	Spatial frequency, mean (SD)	Color entropy, mean (SD)	Luminosity, mean (SD)
Positive	24.51 (1.95)	3.88 (0.19)	78.97 (9.13)
Neutral	23.71 (3.03)	3.84 (0.18)	81.55 (11.46)
Negative	22.52 (2.78)	3.80 (0.20)	85.28 (12.98)

Shapiro-Wilk tests were used to assess normality, and 1-way ANOVAs or Kruskal-Wallis *H* tests were applied as appropriate. Descriptive distributions of the 3 perceptual features across valence categories are presented in Figure 3. Shapiro-Wilk tests indicated that distributions were approximately normal for spatial frequency and color entropy across groups, but not for luminosity (neutral group W=0.913; P=.04). Accordingly, 1-way ANOVAs were used for spatial frequency and color entropy, and a Kruskal-Wallis test was used for luminosity. A significant effect of valence was observed for spatial frequency ($F_{2,72}$=3.61; P=.03) driven primarily by differences between neutral and negative images. No significant differences were found for color entropy ($F_{2,72}$=1.15; P=.32) or for luminosity (H_2=2.95; P=.23). Because neutral images were not carried forward into the AMP task (phase 2), the spatial frequency effect was not considered relevant. Positive and negative image sets, which served as primes in phase 2, were comparable across all 3 perceptual dimensions.

XSL•FO
RenderX

Figure 3. Box plots of perceptual features by valence category: (A) spatial frequency, (B) color entropy, and (C) luminosity.

Behavioral Ratings

Reliability of Ratings

Interrater reliability was assessed for valence, arousal, and relevance ratings using ICC(2,k) (2-way random effects model and absolute agreement [17]; Table 4). Because each participant rated either valence or arousal, but all rated relevance, per-image ICCs could not be estimated; instead, overall reliability estimates are reported. Results indicated excellent agreement for valence (ICC=0.99, 95% CI 0.99-0.99) and good agreement for relevance (ICC=0.81, 95% CI 0.75-0.87) and arousal (ICC=0.77, 95% CI 0.68-0.84; all P<.001; Table 2). Split-half correlations yielded similar results (valence r=0.986, arousal r=0.839, and relevance r=0.801), supporting the robustness of these estimates. Together, these findings demonstrate that ratings were highly consistent across participants.

Table . Intraclass correlation coefficients (ICC[2,k]) for interrater reliability of image ratings.

Dimension	ICC(2,k); 95% CI	*F* value (*df*)	*P* value
Valence	0.99; 0.99-0.99	105.96 (72, 1368)	<.001
Arousal	0.77; 0.68-0.84	5.99 (72, 1368)	<.001
Relevance	0.81; 0.75-0.87	7.12 (72, 2808)	<.001

Filtering and Categorization

To ensure that the stimulus set was thematically relevant and affectively unambiguous, images were filtered in several steps. First, we excluded images with mean relevance ratings below 4 on a 7-point scale. Second, images showing high variability across raters (SD≥1.5 for valence or relevance) were removed to eliminate ambiguous stimuli. Third, arousal ratings were standardized, and images outside the 95% CI (z-scores ±1.96) were excluded to reduce the influence of atypical extremes. Finally, participant ratings were compared with intended valence categories. Whereas positive and negative sets were retained, most neutral images were inconsistently classified; only 5 neutral images passed the criteria, which was deemed insufficient and unreliable. Consistent with affective norming practices (eg, IAPS [International Affective Picture System] and OASIS [Open Affective Standardized Image Set]) [18,19], neutral primes were therefore operationalized as perceptually simple gray squares in the subsequent AMP task.

From the filtered pool, 5 positive and 5 negative images were retained as primes for the AMP. All selected stimuli were rated as moderately arousing, with mean ratings falling within the 3.5 to 4.5 range. A Welch 2-tailed t test confirmed that mean arousal did not differ significantly between the positive (mean 4.15, SD 1.60; n=100) and negative (mean 4.17, SD 1.65; n=100) sets (t_{198}=–0.09; P=.93). These results indicate that emotional intensity was successfully balanced across affective conditions.

Phase 2: IA-AMP

AMP Effects

The primary positive-negative AMP analysis used the final validated affective-prime set of 5 positive and 5 negative images (gray-square baseline trials were excluded). Data were analyzed using a trial-level binomial GLMM that included prime valence, prime duration, their interaction, and batch as fixed effects, along with random intercepts for participant and prime image. The prime valence × prime duration interaction significantly improved model fit, as assessed by a likelihood-ratio test (χ^2_2=38.1; P<.001), indicating that the positive-negative AMP effect varied across durations.

Descriptively, the raw AMP effect (the positive-negative gap in pleasant judgments) was smallest at 75 milliseconds (0.480) and increased to 0.625 at 350 milliseconds and 0.658 at 425 milliseconds. Full descriptive proportions and model-based estimates for each condition are reported in Table 5 and displayed in Figure 4.

XSL•FO
RenderX

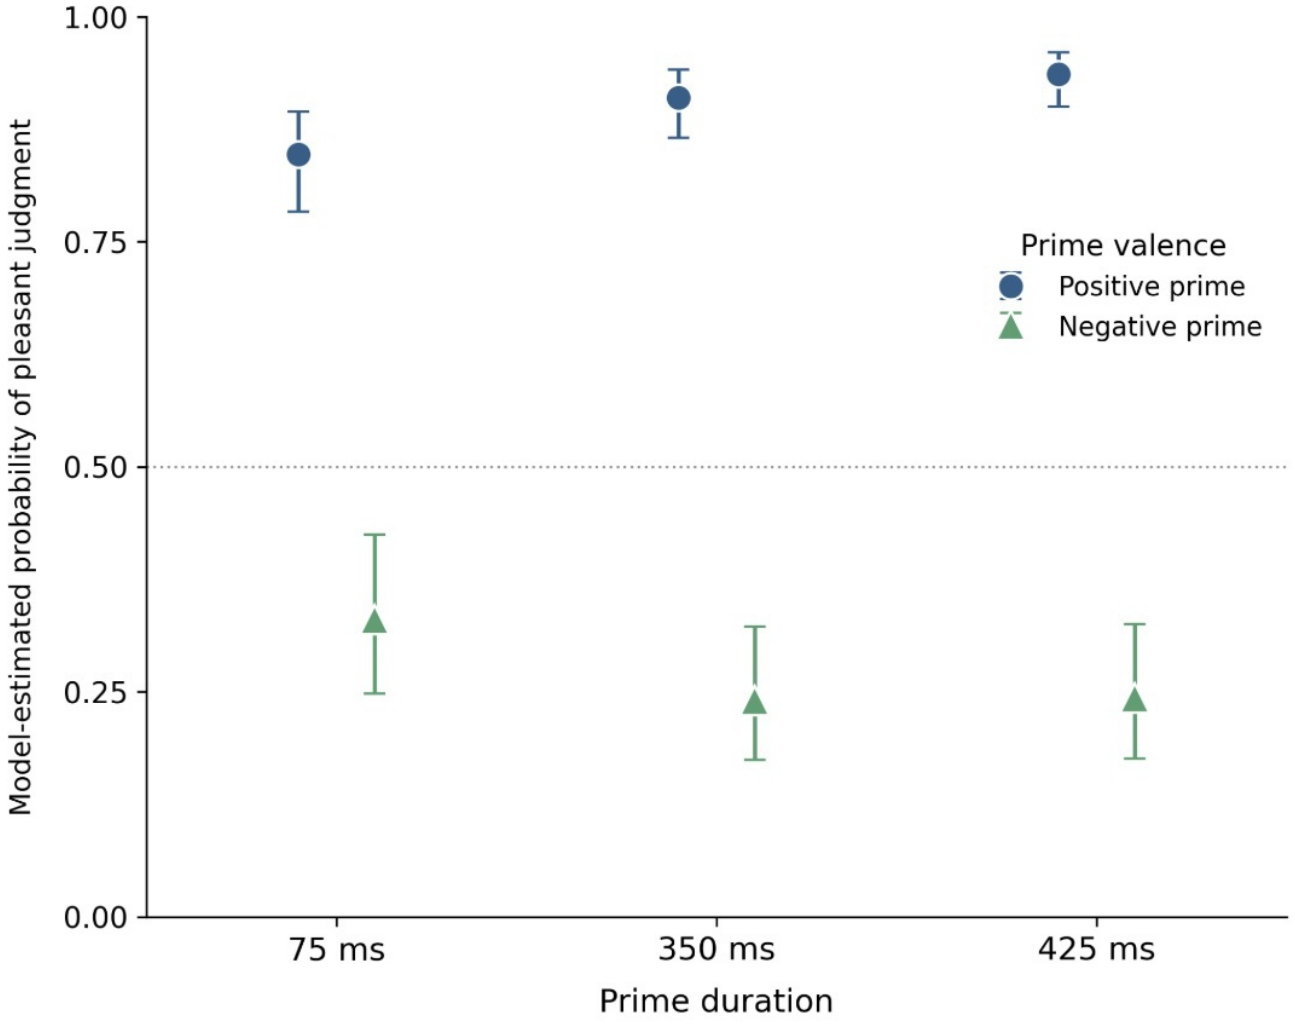

Table . Proportion of pleasant judgments, raw affect misattribution procedure (AMP) effects, and model-based contrasts by prime valence and prime duration[a].

Prime duration (ms)	Positive Pr(pleasant)	Negative Pr(pleasant)	Raw AMP effect	OR[b] (95% CI)	*P* value
75	0.827	0.347	0.480	11.2 (5.8-21.6)	<.001
350	0.889	0.264	0.625	31.9 (16.0-63.4)	<.001
425	0.921	0.263	0.658	45.6 (22.1-94.0)	<.001

[a]Positive Pr(pleasant) and Negative Pr(pleasant) are pooled trial-level proportions. Raw AMP effect = Positive Pr(pleasant) − Negative Pr(pleasant). OR is the odds ratio for positive vs negative prime contrast at each duration, estimated from the primary trial-level binomial GLMM. *P* values are Holm-adjusted across the 3 duration-specific contrasts.

[b]OR: odds ratio.

Figure 4. Model-estimated probability of a pleasant judgment by prime valence and prime duration. Circles represent estimated marginal probabilities for positive primes, and triangles represent negative primes, derived from the trial-level binomial generalized linear mixed-effects model (GLMM), averaged proportionally over batch, with 95% CIs back-transformed from the logit scale. The dotted line marks chance responding (0.5). Follow-up model-based contrasts showed that the positive-negative difference was smaller at 75 ms than at 350 and 425 ms (both Holm-adjusted *P*<.001), whereas the differences at 350 and 425 ms did not differ significantly (*P*=.17). Model-estimated probabilities differ slightly from the raw proportions in Table 5 because the GLMM adjusts for crossed random intercepts and is averaged proportionally over batch.

Holm-corrected positive vs negative contrasts were significant at all durations: positive primes increased the odds of a pleasant judgment relative to negative primes by a factor of 11.2 at 75 milliseconds, 31.9 at 350 milliseconds, and 45.6 at 425 milliseconds (all *P*<.001; 95% CIs given in Table 5).

The magnitude of this effect differed by duration. The positive-negative contrast was significantly smaller at 75 milliseconds than at 350 milliseconds (log-odds difference=−1.046; *P*<.001) and at 425 milliseconds (log-odds difference=−1.404; *P*<.001). The contrast did not differ significantly between 350 and 425 milliseconds (log-odds difference=−0.359; *P*=.17). Affect transfer was, therefore, robust at all durations but weaker at 75 milliseconds than at the 2 longer durations, which were statistically comparable.

An item-control sensitivity model adding target-image random intercepts produced the same substantive fixed-effect pattern,

XSL•FO
RenderX

with the prime valence × prime duration interaction remaining significant (χ^2_2=38.1; *P*<.001). The target-image SD was minimal (0.09 on the logit scale) relative to the participant and prime-image SDs (0.63 and 0.36, respectively), suggesting that the observed AMP effects were not primarily attributable to idiosyncratic features of particular target images.

Batch Sensitivity Analyses

Batch sensitivity analyses were conducted to evaluate whether AMP effects differed across the 2 sequential cohorts. A model allowing batch interactions improved fit relative to the primary model (χ^2_5=21.79; *P*<.001), indicating that batch moderated some aspects of the response pattern. Follow-up contrasts showed significant positive-negative priming at all durations in both batches. In batch 2A, positive vs negative ORs were 7.23 at 75 milliseconds, 25.19 at 350 milliseconds, and 31.86 at 425 milliseconds (all *P*<.001). In batch 2B, the corresponding ORs were 18.52, 43.32, and 72.82 (all *P*<.001).

However, the targeted prime valence × prime duration × batch interaction was not significant (χ^2_2=0.76; *P*=.68). This indicates that although batch 2B showed stronger overall positive-negative priming, the duration-dependent pattern of priming did not differ reliably between batches.

Because the 2 cohorts also differed in age and education (see Participants and Design section), we refitted the primary model adding participant age, sex, and education as covariates to assess whether these differences accounted for the priming effect. The prime valence × prime duration interaction remained significant (χ^2_2=38.0; *P*<.001), and none of the covariates significantly predicted pleasant judgments (for age *P*=.56, for sex *P*=.83, and for education *P*=.48). The duration-dependent priming pattern was therefore not attributable to differences in cohort composition.

Awareness Responses

No awareness responses were recorded in batch 2A under the initial awareness-probe interface. To clarify this zero-response pattern, 20 of the 29 batch 2A participants completed brief posttask probes in Mandarin. Responses were summarized descriptively and suggested that the absence of awareness responses reflected a combination of interface-related barriers, task-load issues, and conservative use of the awareness key, rather than definitive evidence of no prime awareness.

Awareness analyses were, therefore, restricted to batch 2B, where the simplified awareness interface was used. In batch 2B, reported influence awareness was common. Participants reported awareness of the preceding prime's influence on 57.5% of prompted trials at 75 milliseconds, 66.2% at 350 milliseconds, and 68.3% at 425 milliseconds. A binomial mixed-effects model confirmed that awareness increased with prime duration: awareness was significantly lower at 75 milliseconds than at 350 milliseconds (*P*=.004) and 425 milliseconds (*P*<.001), with no significant difference between 350 and 425 milliseconds (*P*=.52). Participant-level summaries indicated that awareness reports were not limited to a small subset of participants. All 27 batch 2B participants reported at least 1 awareness event at each duration.

These findings indicate that the simplified batch 2B awareness-interface successfully elicited awareness reports, but they also show that reported influence awareness was frequent. Therefore, phase 2 should not be interpreted as showing that AMP effects occurred under minimal or absent awareness.

Awareness-Stratified AMP Effects

Exploratory awareness-stratified summaries showed that reported influence awareness substantially shaped AMP effects in batch 2B. On awareness-reported trials, target judgments were highly aligned with prime valence. Pleasant-response rates following positive primes were 92.0%, 94.0%, and 96.1% at 75, 350, and 425 milliseconds, respectively, whereas corresponding rates following negative primes were 4.5%, 3.0%, and 3.7%. This produced raw awareness-reported AMP effects of 0.875, 0.910, and 0.924, respectively.

On trials without reported awareness, positive-negative differences were much smaller. Pleasant-response rates following positive vs negative primes were 78.8% vs 77.3% at 75 milliseconds, 81.6% vs 73.5% at 350 milliseconds, and 85.6% vs 70.6% at 425 milliseconds, corresponding to raw AMP effects of 0.016, 0.081, and 0.150, respectively. These descriptive patterns indicate that the overall AMP effect was strongly associated with reported influence awareness (Table 6).

Table . Awareness-stratified pleasant-response proportions in batch 2B[a].

Prime duration (ms)	Awareness status	Negative Pr(pleasant)	Positive Pr(pleasant)	Raw AMP[b] effect
75	Aware	0.045	0.920	0.875
75	Unaware	0.773	0.788	0.016
350	Aware	0.030	0.940	0.910
350	Unaware	0.735	0.816	0.081
425	Aware	0.037	0.961	0.924
425	Unaware	0.706	0.856	0.150

[a]Proportions are descriptive trial-level values from batch 2B only (n=27). Awareness status reflects whether participants reported that the preceding prime influenced their judgment on a given trial. Raw AMP effect = Positive Pr(pleasant) − Negative Pr(pleasant).

[b]AMP: affect misattribution procedure.

XSL•FO
RenderX

Because awareness-reported trials showed near-complete separation, with highly consistent pleasant responses following positive primes and unpleasant responses following negative primes, ORs from awareness-stratified logistic models were extremely large and are not emphasized in the main text. The cell-level proportions provide a more interpretable summary of the awareness-stratified pattern.

Summary of Timing Pattern

Across both batches, the IA-AMP produced robust positive-negative affect-transfer effects. The effect was significantly smaller at 75 milliseconds than at 350 milliseconds and 425 milliseconds, whereas 350 milliseconds and 425 milliseconds did not differ significantly. Batch 2B showed stronger overall priming than batch 2A, but the duration-dependent pattern was consistent across batches.

The results did not identify a duration that simultaneously maximized affect transfer and minimized awareness. The 75-millisecond duration showed the lowest reported awareness but the weakest overall AMP effect. The 425-millisecond duration showed the largest descriptive AMP effect but also the highest reported awareness and the longest exposure duration. The 350-millisecond duration produced strong affect transfer comparable to 425 milliseconds while avoiding the longest exposure duration. Therefore, 350 milliseconds is best interpreted as a practical calibration point rather than a strictly low-awareness or fully implicit optimum. Reported influence awareness remained common and should be monitored and modeled in future older-adult AMP studies.

Discussion

Principal Findings

This study adapted and evaluated the IA-AMP to assess older adults' affective responses toward digital health technologies. Phase 1 developed and validated age-relevant prime images depicting older adults in digital health contexts. The final positive and negative prime sets were emotionally distinct and comparable in arousal and low-level perceptual features, whereas neutral human images were not consistently rated as neutral and were, therefore, replaced by gray-square baseline stimuli in phase 2, consistent with prior AMP work [9].

Phase 2 evaluated AMP sensitivity across prime durations and examined the reported influence of awareness during affect transfer. Across 2 batches, participants were significantly more likely to judge ambiguous targets as pleasant following positive digital health primes than following negative primes. The magnitude of this effect was duration-dependent: the positive-negative contrast was significantly smaller at the standard 75 milliseconds duration and stronger at both longer durations, with no reliable difference between 350 and 425 milliseconds. This pattern suggests that very brief prime exposure may be insufficient for older adults, whereas moderately extended exposure improves affect transfer. This finding is consistent with broader evidence of age-related slowing in visual and cognitive processing speed [20,21], suggesting that standard AMP timing parameters developed for younger adults may require modification for older adults.

Awareness responses were not observed in the first batch but emerged after interface refinement in batch 2B. Posttask debriefings with batch 2A participants indicated that the absence of responses reflected interface comprehension barriers and conservative key-press behavior rather than a definitive absence of prime awareness. In contrast to the original expectation that awareness would remain relatively low, reported influence awareness in batch 2B was common, exceeding half of prompted trials at all durations. Awareness-stratified summaries further indicated that reported influence awareness substantially shaped the AMP effect, consistent with Hughes et al [13]. On awareness-reported trials, target judgments were highly aligned with prime valence, whereas positive-negative differences were much smaller on trials without reported awareness. These findings show that the IA-AMP can produce robust affect-transfer effects in older adults while also revealing that reported influence awareness plays an important role in those effects. Taken together, the results support 350 milliseconds as a practical timing point for older adults. It produced strong affect transfer comparable to 425 milliseconds while avoiding the longest exposure time, though it should not be interpreted as a strictly low-awareness or fully unconscious parameter.

The contrast between batch 2A and batch 2B is best interpreted as a methodological finding about awareness-probe design. The core IA-AMP target judgment task was unchanged across cohorts, and the awareness prompt appeared only after the pleasant or unpleasant target judgment had already been recorded. Batch-interaction sensitivity analyses showed that the duration-dependent priming pattern did not differ reliably between cohorts, supporting the robustness of the primary AMP finding. The zero-response pattern in batch 2A, therefore, limits awareness-related interpretation but does not compromise the primary AMP target-judgment outcome. Instead, it highlights that awareness probes for older adults must be designed with response accessibility, instruction clarity, and task burden in mind.

Comparison With Prior Work

This work extends the AMP literature by situating the present findings at the intersection of cognitive aging, visual processing, and methodological debates about the role of awareness in AMP effects. First, in relation to cognitive aging, the study applies the AMP to older adults, a population that has rarely been the focus of AMP methodological development. Earlier AMP work showed that evaluative priming can emerge across relatively fast and slower presentation rates [14,22], but much of this evidence was generated in younger adult samples and nonhealth attitude domains. In the present study, the shortest duration produced the weakest positive-negative contrast, whereas the 2 longer durations produced stronger and statistically comparable effects. This pattern is compatible with the idea that older adults may require somewhat longer stimulus exposure for reliable perceptual registration and evaluative carryover [20,21], even when the basic AMP mechanism remains intact. The study also extends the ecological scope of the AMP by using age-relevant digital health imagery, rather than the racial, political, or general social attitude stimuli that dominate much earlier work [7], showing that ambiguous targets can be

XSL•FO
RenderX

systematically biased by digital health primes in a later-life context.

Second, the awareness findings also place the present study within ongoing debates about the role of awareness in AMP effects across the broader implicit-cognition literature. Classic AMP accounts conceptualize the task as an indirect measure of automatically retrieved evaluative responses [9]. More recent work by Kurdi et al [14] suggests that awareness reports may sometimes be outcomes of AMP-consistent evaluative responding rather than causes of AMP effects, cautioning against treating reported awareness as straightforward evidence that awareness drove the AMP effect. In contrast, Hughes et al [13] argue that influence awareness can strongly moderate AMP effects, either by amplifying affect transfer through conscious re-evaluation or by qualifying the task's status as a measure of implicit attitudes. The present findings do not resolve this broader theoretical dispute, but they show that, in an older adult digital health context, reported influence awareness materially shaped the interpretation of AMP scores. Overall, priming was robust, but reported influence awareness was frequent, and awareness-reported trials showed much stronger positive-negative differences than trials without reported awareness. Thus, the influence-aware design was not merely an added procedural feature; it was central to interpreting what the task measured. An additional consideration specific to this population is that older adults characteristically prioritize accuracy over speed and adopt more conservative response thresholds than younger adults [23]. This tendency may extend to awareness reporting such that older adults who detect any prime-related internal reaction are more inclined to endorse an explicit awareness probe when prompted, producing a conservative reporting bias that may have contributed to elevated trial-level awareness rates beyond what strict conscious prime recognition alone would predict. These findings suggest that IA-AMP effects in older adults should be interpreted as affect-transfer responses measured alongside awareness, rather than as straightforward evidence of awareness-free implicit attitudes or pure affect misattribution [13,24].

Implications for Digital Health Research

The present findings have several implications for digital health research and evaluation with older adults when interpreted alongside adoption research showing that older adults' technology use is shaped not only by perceived usefulness or ease of use [25,26], but also by emotional, social, relational, and contextual factors [27,28]. Prior work has consistently documented barriers to older adults' digital health engagement, including limited digital literacy, physical and cognitive challenges, usability problems, privacy concerns, mistrust, and technology anxiety, alongside facilitators such as accessible design, provider endorsement, social support, and co-design [27-29]. Taken together, this body of work suggests that emotional and trust-related responses are not peripheral to digital health engagement—they are part of the adoption process itself.

The IA-AMP contributes a complementary measurement approach for studying affective barriers that conventional self-report methods may not fully capture, particularly given older adults' susceptibility to social desirability bias and limited introspective access to automatic emotional reactions [4]. Innovation Resistance Theory helps situate what those affective barriers may represent by distinguishing functional barriers, such as usage, value, and risk, from psychological barriers, such as tradition and image, and by framing resistance as an active response rather than a passive failure to adopt [30]. In digital health contexts, older adults' resistance may involve emotional discomfort, symbolic misalignment, fears about losing relational care, privacy and data-security concerns, distrust in diagnostic accuracy, and skepticism about care quality [31]. Low self-efficacy and technology anxiety may further create feedback loops that reinforce avoidance behaviors. The present findings are consistent with this perspective: digital health primes elicited rapid affective responses that biased target judgments, suggesting that affective and image-related components of resistance may be measurable at the trial level. Incorporating the IA-AMP into standard technology evaluation pipelines in community or clinical settings would allow developers to assess the "affective usability" of a digital health tool, its capacity to foster emotional comfort and trust, alongside traditional functional usability metrics.

Limitations and Strengths

The primary strength of this work lies in demonstrating that IA-AMP can be adapted for older adults and digital health imagery with a relatively low technical burden. The study was intentionally designed with several simplifications to balance methodological control and participant accessibility. Participants completed the task on standard desktop computers under researcher supervision, suggesting that the procedure is feasible in clinical or applied research settings.

While the sample sizes were modest (phase 1: n=40; phase 2: n=56), they were appropriate for a feasibility study and consistent with prior AMP and implicit-attitude research [32]. Nonetheless, this sample limits generalizability and precludes the examination of subgroup differences (eg, by age or cultural background). Larger and more diverse cohorts will be needed to evaluate the stability of IA-AMP effects, establish psychometric reliability, and test predictive validity against real-world measures of technology adoption, which is necessary before clinical relevance can be established.

The sequential recruitment of the 2 cohorts introduces limitations that shape the interpretation of both the primary and awareness-specific findings. The original batch 2A awareness-interface yielded no recorded responses and was subsequently simplified for batch 2B. Furthermore, the cohorts differed in baseline characteristics, with lower-education participants and a modest age difference concentrated in batch 2A. Although adjusting for age, sex, and education indicated that these demographic differences did not account for the primary AMP effect, the potential influence of temporal context arising from sequential recruitment cannot be fully ruled out. Consequently, while the core duration-dependent priming pattern was robust across both batches, the awareness-related conclusions are tied to the simplified batch 2B interface. Finally, reported influence awareness was common in batch 2B, suggesting that IA-AMP effects in this context reflect

XSL•FO
RenderX

affect-transfer responses measured alongside awareness rather than in its absence.

Taken together, the findings indicate that the IA-AMP is a feasible and scalable method for assessing older adults' affective responses to digital health technologies. Its brevity, low verbal demand, and computerized format make it potentially useful as a complementary method in digital health evaluation, particularly when used alongside self-report, usability testing, and awareness assessment. However, its value should not be understood as providing a simple, awareness-free measure of hidden attitudes. Rather, the IA-AMP may be most useful as part of a multimethod evaluation framework that captures affect-transfer responses while explicitly monitoring reported influence awareness.

Conclusions and Future Directions

The present work demonstrates the feasibility of using the IA-AMP to assess older adults' affective responses to digital health technologies. A prime duration of approximately 350 milliseconds produced strong affect transfer comparable to 425 milliseconds while avoiding the longest exposure duration. These findings suggest that moderately extended prime durations provide a practical timing point for older-adult AMP studies, improving affect-transfer sensitivity relative to very brief exposures. The findings also demonstrate that reported influence awareness must be measured and modeled when using AMP paradigms with older adults. Future studies should expand on this foundation by recruiting larger and more diverse cohorts to evaluate the stability of IA-AMP effects, examining psychometric reliability and predictive validity in relation to real-world digital health engagement, and incorporating richer awareness measures to clarify the boundary between automatic and conscious affect transfer. The next phase of research should also integrate the IA-AMP into participatory design and implementation studies to test whether reducing implicit negativity or enhancing positive affect toward digital health technologies improves adoption and sustained use. Advancing this approach from feasibility to validated measurement will be critical for developing technologies that older adults not only can use but are also willing and affectively prepared to engage with in later life.

Abstract

Background: Older adults often face challenges using digital transportation planning tools to engage in meaningful activities. In Sherbrooke, a Canadian city located in the province of Québec, hilly terrain, bus-based mobility, and varied digital literacy among older adults highlight the need for accessible transportation planning technologies. Despite the growing demand for accessible and inclusive technologies, interfaces are often not tailored to the specific needs and preferences of older adults, making them difficult to use. Addressing this gap is essential to support the mobility and social participation of older adults in their communities.

Objective: This study aimed to enhance older adults' experience with a transportation planning e-tool—called Mobilainés—by co-designing its interface and evaluating its usability and user experience in line with their needs and preferences.

Methods: Using a participatory design approach, the study encompassed both development and evaluation phases, integrating qualitative and quantitative methods. In the development phase, heuristic evaluation, along with the Mobilaînés mock-up, was performed to identify the percentage of compatibility with age-friendly usability design principles and guidelines. Fourteen co-design workshops with the steering committee and research team informed persona development and core functionalities, while 3 workshops with older adults refined the mock-ups. For the evaluation phase, 2 laboratory usability tests (simulated context) and 1 in-field test (real-world context) were conducted with 5, 7, and 4 older adults, respectively. Data were collected using a combination of objective performance metrics recorded in real time by a computer and subjective user feedback, gathered using the System Usability Scale, the Unified Theory of Acceptance and Use of Technology questionnaires, and focus group discussions. For the in-field testing, user experience data were obtained via the User Experience Questionnaire and semistructured interviews. Quantitative data were analyzed descriptively, and qualitative data were analyzed thematically.

Results: The participatory design and iterative evaluation process identified key design decisions for age-friendly transportation planning, including step-by-step navigation, simplified task flow, clear feedback, visual clarity, and personalization. In the final laboratory usability test, the Mobilaînés e-tool showed 84% compatibility with age-friendly guidelines, a 97% task completion rate, and System Usability Scale and Unified Theory of Acceptance and Use of Technology scores corresponding to very good usability. In-field User Experience Questionnaire results and interviews suggested that participants perceived the e-tool as reliable, easy to use, and accurate, despite the lack of real-time data.

Conclusions: Participatory design and iterative usability testing revealed that older adults' experience with Mobilainés transportation planning e-tools is improved. These design learnings contributed to improved usability and confidence in real-world travel planning, offering practical guidance for the development of age-friendly digital transportation tools. Future research should explore collaborative and technological strategies to support its adoption and sustained use, particularly among older adults with limited digital literacy.

Introduction

Background

Worldwide, the aging population will increase from 900 million (2015) to 2 billion by 2050 [1]. In Canada, it is expected to reach 15.1 million by 2063 [2]. Age-related changes, such as declining vision [3], reduced mobility [4], and cognitive decline, may hinder traffic signs recognition, decrease flexibility, and slow reaction times while driving [5], which can limit older adults' ability to drive safely and travel independently [6]. Additionally, financial constraints [7], rural living [8], and small social networks [9] further restrict access to transportation options. These challenges increase the risk of sedentary behavior, isolation [10,11], loneliness [11], and anxiety [12]. To enable older adults to maintain their independence and engage in community life—key elements of social participation [13]—it is therefore essential to strengthen older adults' ability to access and use transportation options that reflect their specific needs, including those involving emerging technologies.

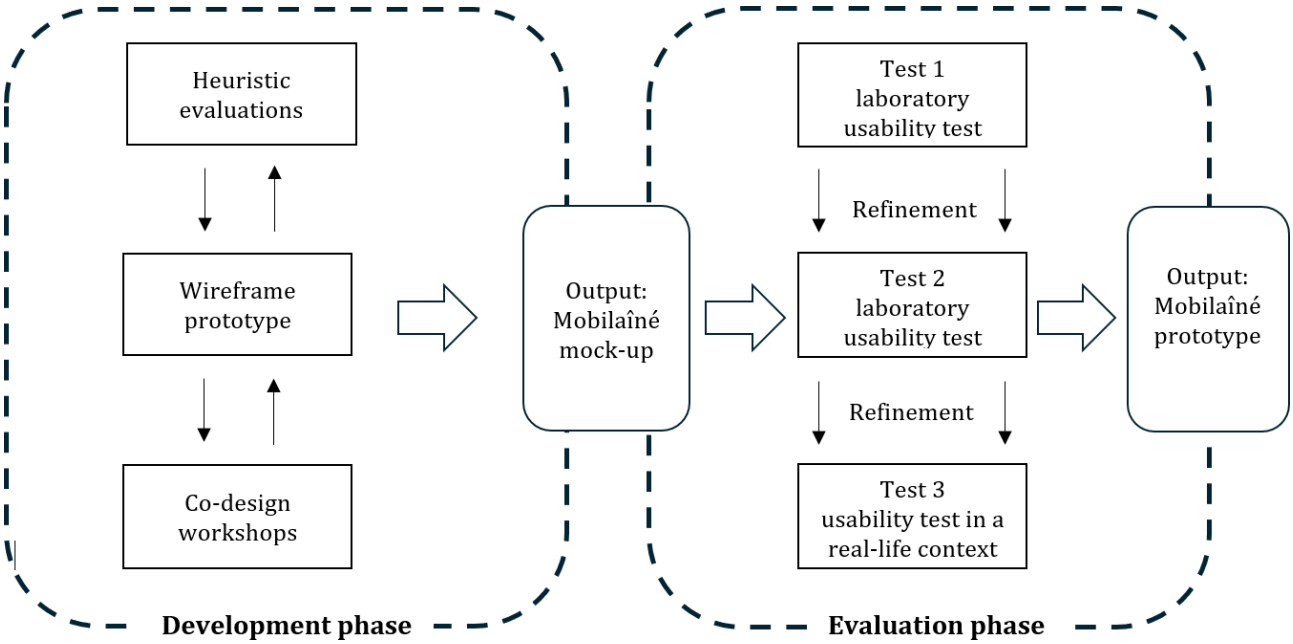
Digital transportation planning tools (websites and apps) are intended to support users in accessing information, selecting transportation options, and organizing their travel. While these tools have the potential to improve mobility, they often pose considerable usability challenges for older adults. Age-related changes, such as decreased visual acuity [14], reduced contrast sensitivity [15], and diminished dexterity [16], can make it difficult for them to identify important interface elements, interpret maps, and accurately interact with touch or clickable components [17]. In addition to these sensory and motor declines [4], cognitive changes associated with aging, such as reduced executive functioning, can impair an individual's ability to navigate complex transportation systems or coordinate multistep travel plans [6]. Digital literacy [18] also remains a key barrier; limited familiarity with technology can restrict access to real-time transportation updates or adaptive features within e-tools [19]. Differences in numerical comprehension and screen navigation further emphasize the need for design solutions that reflect the diverse abilities of this population [20].

Beyond usability considerations, digital transportation planning tools may influence older adults' mobility and well-being through psychological and cognitive mechanisms. Accessible and intuitive interfaces can reduce cognitive demands, helping users process information more efficiently and make travel decisions with less effort [21]. This may enhance perceived control over travel and strengthen mobility-related self-efficacy, understood as confidence in one's ability to plan and complete trips, particularly because older adults' transition to public transit use involves acquiring travel-planning skills and confidence through experience [22]. Together, greater perceived control and self-efficacy may encourage more frequent and independent use of transportation options, supporting social participation and well-being. Conversely, poorly designed interfaces may increase cognitive burden, reduce confidence, and discourage engagement with transportation systems [23].

Addressing such specific needs of older adults is vital for creating inclusive tools that enhance their user experience and support independent mobility. A participatory design approach is especially valuable for ensuring that these needs are fully integrated into the development and evaluation of transportation planning interfaces. Participatory design, sometimes known as cocreation or co-design [24], is described as a collaborative process in which various participants engage in shared exploration, understanding, and learning through ongoing reflection and action [25]. Among other benefits, participatory design contributes to a better user experience, as it is conceived with the end users in mind rather than simply tested by them [26]. User experience is defined as "an iterative set of decisions leading to a successful outcome with an interactive tool, as well as a productive and satisfying process to achieve that outcome" [27]. To enhance the user experience of older adults when using a travel planning e-tool, it is important to design an interface that is specifically adapted to their specific needs and allows them to perform their intended tasks easily, intuitively, and without confusion or interruption [28]. Given the notable lack of studies specifically focused on developing and evaluating transport planning interfaces tailored to the needs and preferences of older adults through a participatory design approach [28], addressing this gap is essential for enhancing their user experience with transportation planning e-tools.

Context of Study and Objective

The aim of this study is to improve older adults' experience in using a transportation planning e-tool—called Mobilaînés—by co-designing its interface and evaluating its usability and user experience based on their needs and preferences. Rather than introducing a new mode of transportation, Mobilaînés [29] was designed to integrate existing options, helping older adults make informed travel decisions and supporting their autonomy in everyday life, using a living laboratory methodology [30]. The study took place in Sherbrooke, a city in the province of Quebec, Canada, characterized by its hilly terrain, and its main public transportation is an urban bus service. These environmental characteristics may create mobility challenges for older adults, especially those with reduced endurance, mobility limitations, or unfamiliarity with public transit. In addition, despite increasing digital technology use among older adults in Canada, digital literacy, confidence, and access remain uneven, particularly among those with functional or social vulnerabilities [31]. This context highlights the need for transportation planning tools adapted to older adults' capabilities and preferences. The Mobilaînés living laboratory methodology, as well as its algorithm development, is described elsewhere (see Provencher et al [29] and Tahir et al [32] for additional details). The study is guided by the following research question: How does the co-designed Mobilaînés transportation planning interface improve usability and user experience for older adults?



XSL•FO
RenderX

Methods

Study Design

Using a participatory design approach [29], the study had 2 phases using qualitative and quantitative methods: the development phase (May 2020 to July 2022), which focused on the co-design process to ensure that older adults' needs and preferences were considered, and the evaluation phase (August 2022 to August 2024), which examined the usability and user experience of the interface prototype to ensure alignment of the e-tool with the expectations of older adult users (Figure 1).

Figure 1. The development and evaluation process of the Mobilaînés e-tool.

Development Phase

Overview

To co-design the interface of a transportation planning e-tool for older adults, we conducted a heuristic evaluation of existing transportation planning e-tools and the Mobilaînés mock-up, and we carried out a total of 17 co-design workshops with (1) the steering committee, including representatives from municipal and senior advocacy organizations (n=8); (2) the research team, comprising members from communication, computer science, and gerontology (n=10); and (3) older adults (n=5-10).

Heuristic Evaluation

Heuristic evaluation is a widely used expert-based method in which evaluators inspect an interface against a set of usability heuristics to identify design flaws [33], such as supporting *undo* and *redo*. We used the framework of Kumar et al [34], which includes the following phases:

Planning

Transportation planning e-tools that met core functional requirements, such as time autonomy (eg, customizable departure times) and weather integration, were selected in collaboration with the research team [35]. Three websites and 3 mobile apps (Android) were included: the Vermeille App and Website (the transportation planning e-tool provided by Sherbrooke Public Transit at the time of the study), the Google Maps [36] App and Website, the Moovit [37] App, and the OC Transpo [38] Website. The goal was to support the co-design of the Mobilaînés e-tool by documenting the strengths and weaknesses of these transport planning platforms and assessing their alignment with the age-friendly usability design principles and guidelines identified through a scoping review [39]. For additional details on the guidelines, see Multimedia Appendix 1.

Conducting

The heuristic evaluation was initially conducted by an expert evaluator (SBG), who reviewed each e-tool against the age-friendly usability design principles and guidelines identified in the scoping review. Each platform was used repeatedly and reviewed twice to explore its features, functionalities, and interaction pathways. Screenshots of each interface were captured and used during the heuristic evaluation. Findings were documented in structured notes by mapping interface elements to the corresponding heuristics, recording each guideline as compatible or noncompatible, and documenting each issue's location, related heuristic, and potential impact on older adults' ability to understand, navigate, or complete the task. The results were then reviewed and discussed within the research team. Identified usability issues were presented and justified using the heuristic framework, allowing collective reflection and validation of findings and helping refine the interpretation of heuristic violations and compatibility across tools.

Reporting

The identified compatibility and noncompatibility with heuristics were categorized and ranked by severity (minor, moderate, and major). Compatible features were summarized in a table highlighting each tool's strengths, while noncompatible features were presented in a separate table listing usability weaknesses. The evaluation was conducted on both desktop (websites) and

XSL•FO
RenderX

mobile (Android) platforms. Strengths and weaknesses of each e-tool were documented, with particular attention paid to compatibility with age-friendly principles. Recommendations for improvement were then proposed.

Based on the findings, 3 mock-ups for the Mobilaînés website were produced, reviewed with the research team and older adults during co-design activities. Their feedback informed the selection and refinement of the mock-up that best aligned with older adults' needs and preferences, user experience considerations, and the travel-planning algorithm [28,35]. The selected mock-up was then evaluated heuristically by SBG using the same framework [34], with a specific focus on age-friendly usability principles to ensure alignment and identify areas for improvement. The evaluator reviewed the guidelines and assessed whether they were consistently applied across all dimensions of the e-tool.

Co-Design Workshops

Workshops Overview

The development of the Mobilaînés e-tool was grounded in cocreation principles, particularly through workshops that brought together multiple stakeholders (eg, older adults, researchers, municipal representatives, and senior advocacy organizations) using a participatory design [28]. The methods used in the Mobilaînés co-design workshops were informed by Sanders' [40] participatory design framework, and focused on engaging participants in generating, discussing, and refining design ideas. This approach supports the creation of concrete and actionable outputs, such as mock-ups, to inform subsequent development phases [41]. The cocreation workshops involved (1) with the steering committee to develop older adults' personas, (2) with the research team to identify the functionalities of the Mobilaînés mock-up, and (3) with older adults. Lived experience contributors, including older adults and community representatives, played an advisory and co-design role throughout this phase. They contributed by sharing mobility experiences, reviewing personas and mock-ups, identifying usability barriers, and helping prioritize design needs. Their contributions informed the development and refinement of the Mobilaînés interface.

With the Steering Committee to Develop Older Adult Personas

The steering committee guided persona development using the Persona Lifecycle framework [42]. Preliminary personas were developed from semistructured interviews with 6 older adults [29] and a review of scientific and gray literature on aging, mobility, and digital inclusion. Two coconstruction workshops with stakeholders, researchers, municipal representatives, and senior advocacy organizations defined 2 dimensions: mobility profile and planning profile. Mobility profile reflected travel frequency and physical, cognitive, and financial ability to move around, resulting in 4 categories: Mobile Active, Limited Active, Limited Isolated, and Mobile Isolated. Planning profile reflected autonomy in trip planning and access to planning tools, including digital literacy and internet access, resulting in 4 categories: Autonomous Full-Access, Autonomous Limited Access, Dependent Limited Access, and Dependent Full Access. These profiles captured diverse transportation and trip-planning needs and guided recruitment, prototype development, and usage scenarios.

With Research Team to Identify the Functionalities of the Mobilaînés Mock-Up

The scenario-based design technique [43] was used to illustrate common travel-planning issues faced by older adults. This approach incorporated personas and "what if" reasoning to explore both the positive and negative consequences of design choices, helping to assess not only current successes but also the risks of potential changes [43]. In this regard, 3 brainstorming sessions with project team members were conducted using the scenario-based usability engineering technique [44] to (1) identify key functionalities of the e-tool, such as (i) displaying different routes, (ii) providing information on transport options, (iii) presenting travel details (eg, weather, nearby benches, and toilets), and (iv) adapting trip planning to user profiles (eg, walker users); and (2) validating the feasibility of the scenarios. In addition, 9 cocreation workshops were conducted to collaboratively design a preliminary interface for the Mobilaînés e-tool with support from an external agency. Each session involved 8-12 participants, including members of the interdisciplinary Mobilaînés team (from computer science, communication, and gerontology) and an older adult who was a member of the steering committee. Finally, insights from both the co-design sessions and the heuristic evaluation were presented to the research team, informing specific improvements to the selected mock-up ahead of the first usability test.

With Older Adults

Three in-person cocreation workshops were conducted with older adults, with 6-12 participants per session. Eligible participants were older than 65 years, lived in Sherbrooke, and used a computer at least weekly; those unable to travel without human assistance were excluded. Recruitment occurred through municipal and project partners, seniors' residences, posters, and online platforms. Participants were contacted by email and phone to explain the study and assess eligibility and then selected to reflect previously developed personas varying in age, gender, mobility profile, digital competence, travel frequency, and e-tool use. The workshops documented older adults' needs and preferences regarding the Mobilaînés interface and age-friendly features, such as customizable departure times. Feedback on the selected mock-up was documented, thematically analyzed by a research assistant, and validated by 2 principal investigators (VP and DB). Results were integrated into co-design sessions with the research team and design agency to discuss travel-planning challenges and improve the mock-up. The scenarios and mock-up were later evaluated twice by older adults to assess alignment with their expectations. Adjustments were made based on feedback, and perceptions of the interface and functionality were systematically recorded.

All workshops followed a structured but flexible format adapted to session objectives. Steering committee and research team workshops generally lasted 1-2 hours, whereas older adult workshops lasted approximately 3 hours. Sessions typically included (1) presentation of objectives and materials, such as personas, scenarios, or mock-up screens; (2) guided discussion

XSL•FO
RenderX

of transportation planning needs, usability barriers, and expectations; (3) collaborative activities, such as brainstorming, scenario-based discussion, persona review, mock-up walkthroughs, or prioritization of design issues; and (4) synthesis of key decisions and next steps. Outputs included refined personas, prioritized functionalities, user scenarios, annotated mock-ups, usability issues, and design recommendations communicated to the design, programming, and research teams.

Evaluation Phase

Overview

The evaluation comprised 3 experiments: 2 laboratory usability tests and 1 in-field test. According to Nielsen [33], a test with 5 users can reveal 80% of usability issues. Faulkner [45] found that groups of 10 users uncovered 95% of usability issues. Considering possible dropouts, the target sample size was 10, with a minimum of 5 to still capture approximately 80% of practical issues. The same inclusion and exclusion criteria as the co-design workshops were applied, and new participants were recruited for each test to minimize bias. A pretest was conducted with an older adult (aged 65+ years) to ensure that all test materials (eg, scenario tasks, questionnaires, and interview guide) were clear and easy to understand.

Usability Evaluation in a Laboratory Setting

Overview of Usability Evaluation

First, participants (n=7 in test 1; n=5 in test 2) tested the Mobilaînés prototype by completing 3 scenario-based tasks designed to evaluate its usability. These tasks required navigating the interface and entering travel preferences (eg, requesting assistance at the destination). Following guidance on developing usability scenarios and tasks [46], the tasks were designed to reflect realistic travel-planning activities, specify what participants were expected to accomplish, and avoid unnecessary cues about how to use the interface:

1. Task 1: planning a trip while customizing preferences to become familiar with the platform.
2. Task 2: creating and personalizing a user profile, such as saving favorite destinations, to explore additional features.
3. Task 3: planning a future round trip using all the features of the prototype, including both trip directions, save or print options, and personalized settings.

Objective Performance Metrics

The objective performance of participants was assessed using performance metrics to evaluate error tolerance, efficiency, and effectiveness. Observed errors were used to assess error tolerance, task duration measured efficiency (ie, the speed and productivity of task completion), and the number of completed tasks evaluated effectiveness (ie, the success rate of task completion aligned with user expectations). To ensure consistent testing conditions, 3 predefined levels of assistance were provided for participants needing help:

1. Level 1: identifying the problem and clarifying the task.
2. Level 2: providing a clue about the required information and where to find it.
3. Level 3: offering a partial solution by indicating where the information is located on the website.

Assistants (n=4) monitored screens and addressed inquiries according to these guidelines. For each subtask, the outcome was recorded as one of the following: (1) completed without assistance, (2) completed with level 1 assistance, (3) completed with level 2 assistance, (4) completed with level 3 assistance, or (5) not completed. A task or subtask was considered completed when the expected outcome was reached, independently or with predefined assistance. The task completion rate was calculated as completed tasks or subtasks divided by total assigned tasks or subtasks and expressed as a percentage; independent and assisted completion were reported separately. Microsoft Teams recordings of participants' screens and audio were reviewed multiple times to document all observable errors across tasks and subtasks. Errors were summed across participants, tasks, and subtasks for each laboratory usability test. As there was no predefined maximum number of errors per participant or task, participants could make multiple errors and still complete a task independently. All observed errors were documented to capture ease of use, navigation challenges, and alignment with age-friendly usability guidelines. To account for different sample sizes, errors were reported as total counts and observed errors per participant.

Subjective Opinion (User Feedback)

Following task completion, participants completed the validated French version of the System Usability Scale (SUS) [47] to assess perceived usability and satisfaction (Multimedia Appendix 2). This questionnaire demonstrated good convergent construct validity with a single-item measure of user-friendliness (r=0.806) and high internal consistency (Cronbach $\alpha \geq 0.90$) [48]. To evaluate actual usability, participants also completed the Unified Theory of Acceptance and Use of Technology (UTAUT) questionnaire (Multimedia Appendix 3) [49] to measure perceived performance expectancy, effort expectancy, facilitating conditions, and social influence. A customized Mobilaînés UTAUT model was developed to evaluate the effect of these constructs on Behavioral Intention and Behavioral Use (Multimedia Appendix 4), with content tailored to the project.

Subsequently, all participants took part in a focus group to reflect on their satisfaction with sensory navigation, information, and design. Focus group discussions explored participants' overall experience with the Mobilaînés website, elements that enhanced or hindered satisfaction, points of confusion during task completion, comparisons with other planning tools, and their expectations (Multimedia Appendix 5). After analyzing and synthesizing the results of the first laboratory usability test, the e-tool was modified, and all testing procedures were repeated in a second round of usability testing to refine the prototype. The main modifications implemented between the first and second laboratory usability tests included clearer feedback and confirmation messages, improved step indicators and navigation cues, revised icons and colors to enhance visual clarity and consistency, simplified password and account creation guidance, and refined map icons and route-related information to support interpretation of travel options.

XSL•FO
RenderX

Usability Evaluation in a Real-Life Setting

The effects of using the Mobilaînés prototype on older adults' participation in meaningful activities in real-life contexts were explored. Participants (n=4), recruited using the same criteria as in previous usability tests, used the prototype over 6 weeks. Each completed a 1-hour individual introductory session, during which key functions, including account creation, trip planning, saving, and printing, were demonstrated and practiced. Two tutorial videos in French and English were uploaded to the Mobilaînés YouTube channel and emailed to participants to support use and personalization. In weeks 1, 3, and 5, participants were asked by phone to plan trips to 3 Sherbrooke locations; in weeks 2, 4, and 6, the user experience expert followed up by phone to encourage use and address difficulties. Participants were asked to use the tool at least once per week. In weeks 1 and 5, participants completed a paper version of the User Experience Questionnaire (UEQ; Multimedia Appendix 5) to assess satisfaction with the e-tool and changes in user experience over time [50]. The UEQ uses a 7-point Likert scale to assess 6 dimensions: Attractiveness, Perspicuity, Efficiency, Dependability, Stimulation, and Novelty [51] (Multimedia Appendix 6). It has acceptable-to-good reliability (Cronbach α=0.77 - 0.92) and construct validity, with correlations between pragmatic and hedonic factors of r=0.42 (P<.001), and attractiveness correlating strongly with pragmatic (r=0.82) and hedonic (r=0.65) user experience aspects (P<.001). After 6 weeks, participants were invited to final interviews about their use of Mobilaînés, its support or lack of support for meaningful activities, and barriers and facilitators in travel planning and daily participation (Multimedia Appendix 7).

Data Analysis

To address the first objective, selected e-tools (Vermeille app or website, Google Maps app or website, Moovit app, and OC Transpo website) were heuristically evaluated for compatibility with age-friendly usability guidelines. Compatibility was assessed descriptively across phases using the same age-friendly usability guideline framework. Applicable guidelines were classified as compatible or noncompatible, and compatibility percentages were calculated as the number of compatible guidelines divided by total applicable guidelines, multiplied by 100. Using the same framework and calculation method allowed for descriptive comparison across phases. However, the evidence used to assess compatibility differed by phase: during development, compatibility was assessed through expert heuristic evaluation, whereas during laboratory and in-field evaluations, observed usability issues, participant feedback, and evaluation findings were mapped to the same framework. An iterative deductive thematic analysis [52] was conducted by SBG on the verbatim transcripts from the cocreation workshops with older adults, using the age-friendly usability design principles and guidelines [39].

To address the second objective, descriptive analyses of participant characteristics, performance metrics, and SUS, UTAUT, and UEQ scores were conducted in SPSS (IBM Corp). SUS scores below 60 were considered unacceptable, and scores of 90 or above were considered excellent [48]. For UTAUT, a score of 3 on the 5-point Likert scale was treated as the acceptable reference value for each construct item. Focus groups and interviews were recorded, transcribed, imported into NVivo (version 20; Lumivero), and analyzed by SBG using constant comparison, deductively for usability tests and inductively for the in-field test, through open, axial, and selective coding [53]. Given the small sample sizes in the laboratory usability tests and in-field test, all quantitative findings were interpreted descriptively, and no inferential comparisons were conducted between tests. Mean and SD values were retained for questionnaire scores to remain consistent with common reporting practices for the SUS, UTAUT, and UEQ; however, these values were interpreted cautiously.

Ethical Considerations

Ethical approval was obtained from the CIUSSS de l'Estrie-CHUS (2020 - 3389: MOBILAÎNÉS). All participants provided written informed consent after being informed about the study aims and procedures. To protect privacy and confidentiality, data were coded and deidentified during collection, analysis, and reporting. Consent forms and the code key were kept securely in a locked location by the researcher in charge. Research data, including audio and video recordings, were stored confidentially in a locked location for 5 years by the principal investigator (VP). Participants in co-design workshops and laboratory usability tests received US $15 per session, with parking reimbursement when applicable; in-field test participants received US $75 each.

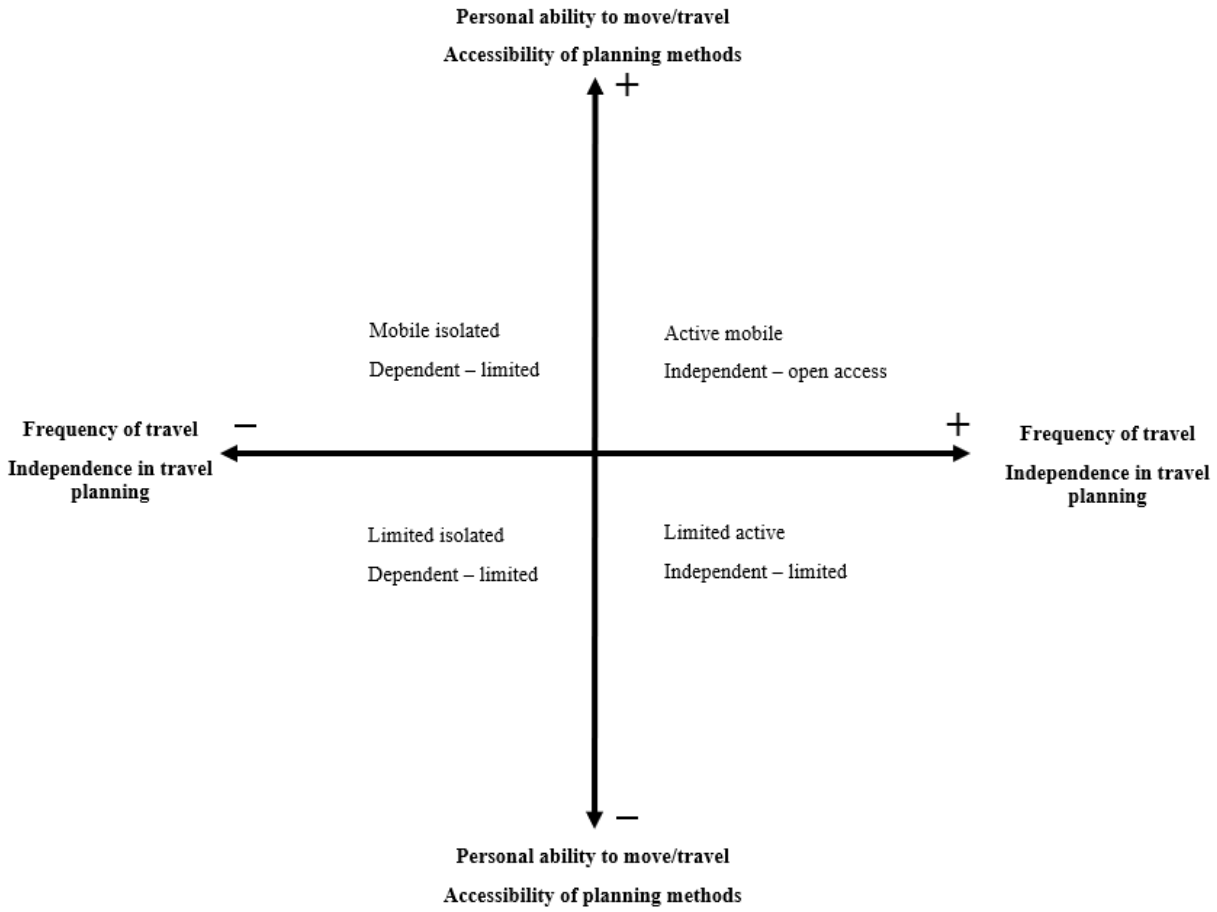
Results

Development Phase

Heuristic Evaluation

A comparison of 3 websites (Vermeille, Google Maps, and OC Transpo) showed that Google Maps had the strongest adherence to age-friendly usability design guidelines (see Multimedia Appendix 8 for details). The heuristic evaluation of the Mobilaînés mock-up showed 67% compatibility with age-friendly usability guidelines. While most information-related guidelines were followed, inconsistencies were noted in key principles such as Simplicity, Control, and Feedback. Specific issues included poor prioritization, repetitive actions, an excessive number of options per page, insufficient color contrast, a small font size, the presence of scroll bars, and a lack of step-by-step guidance. Only 1 guideline related to the Ease-of-Use principle (target size) was not met.

Co-Design Workshops



With the Steering Committee to Develop Older Adults Persona

Four personas were created to reflect older adults' diverse mobility needs, abilities, contexts, and levels of digital literacy (Figure 2). Solange, a 72-year-old woman, is independent, physically active, and confident using digital tools for trip planning, representing users with high mobility and digital confidence. Léonard, a 65-year-old man with diabetes-related functional limitations, has reduced driving ability and limited digital literacy despite computer access. René, an 80-year-old man newly using a tablet provided by his family, depends mostly

XSL•FO
RenderX

on others for outings but is motivated to gain independence, representing users with limited experience but willingness to learn. Suzanna, a 78-year-old recent immigrant with limited French proficiency, no social support, financial constraints, pain, and unfamiliarity with public transport, represents users with intersecting linguistic, physical, economic, and digital vulnerabilities. Solange, Léonard, and René were most relevant to Mobilaînés because they could leave home and plan trips with access to technological support. René was specifically used during heuristic evaluations to assess usability for users facing greater challenges. Suzanna could not be represented in the study because she lacked access to digital tools.

Figure 2. Development of personas based on older adults' mobility and trip-planning profiles.

With Research Teams to Identify the Functionalities of the Mobilaînés Mock-Up

The scenario-based design technique guided the definition of the Mobilaînés mock-up features. Based on personas and older adults' co-design feedback, the tool incorporated sheltered bus stops, restrooms, benches, low-light conditions, round-trip and future-trip planning, walking-time adjustment, hill avoidance, profile creation, favorite addresses, and travel history. To improve accessibility and reduce memory load, travel planning was divided into single-task steps, with clear information and feedback.

With Older Adults

Thematic analysis of older adults' co-design feedback highlighted key usability considerations, including personalized travel planning through user profiles and simple, consistent icons, colors, and layouts. Visual clarity was a recurring concern, including font size, color contrast, and distinguishing clickable elements from informational text, such as the Mobilaînés icon and website name. Participants emphasized reducing unnecessary steps in travel planning and profile creation, improving navigation through forward or back options and map zoom, and adding text labels for unclear icons, such as the pencil icon for editing. They also noted that too many route options increased memory load and preferred highlighting 1 selected route in color. Other challenges included understanding path details and using the travel preference personalization page, which had excessive text and small icons. Finally, participants stressed the need for clear feedback after completing a plan and suggested adding a round-trip option at the start.

Synthesis of the Results: Heuristic Evaluation and Co-Design Workshops

Workshop themes from older adults were integrated with mock-up heuristic evaluation results and refined during a Mobilaînés project meeting. Usability issues, including color combinations, font-size buttons, and page layout, were reviewed

XSL•FO
RenderX

using older adults' feedback and age-friendly usability guidelines. SBG documented improvement ideas, and final decisions were based on feasibility and communicated to the interface design, programming, and algorithm teams to prepare the prototype for laboratory usability testing. Some preferences, such as avoiding icy routes, could not be implemented because of limited data quality and development time.

Evaluation

Laboratory Usability Tests

Sociodemographic Overview

In the first usability test, 10 participants were recruited, but 3 were absent due to health reasons, resulting in 7 participants: 5 corresponding to Solange's persona and 2 to Léonard's. Participants were aged between 65 and 78 (mean 71.86, SD 4.85; median 70) years. Four participants identified as female, and 6 held a driver's license. In the second usability test, out of 10 recruited participants, 5 were absent on the testing day, also due to health issues, resulting in 5 participants, all related to Solange's persona. Participants were aged between 66 and 75 (mean 69.4, SD 3.36; median 69) years. In the in-field test, 4 participants aged 67-75 (mean 69.5, SD 3.79; median 68) years were recruited (see Table 1 for more details). Participants were identified using anonymized codes, where "P" refers to the participant number and "T" indicates the test session.

Performance Metrics in Laboratory Usability Tests

Navigation, selection, insertion, and task-understanding errors were identified in both tests and used to assess error tolerance. In total, 46 errors were recorded in test 1 (n=7) and 22 in test 2 (n=5), corresponding to 6.6 and 4.4 errors per participant, respectively (Table 2). Most errors occurred during profile

XSL•FO
RenderX

creation or personalization and round-trip planning. Because sample sizes differed between laboratory usability tests, errors were reported as total observed errors and errors per participant. Task performance was reported by assistance level, using counts and percentages for tasks completed independently, completed with assistance, and not completed.

Regarding *effectiveness*, measured by participants' ability to complete tasks with or without assistance, most participants were able to complete the simpler tasks independently, while more support was required for the more complex ones (Table 3).

Table . Observed errors in laboratory usability tests.

Error metric	Test 1 (n=7)	Test 2 (n=5)
Error in task 1: 1-way trip	5	6
Errors in task 2: profile creation or personalization	18	5
Errors in task 3: round-trip planning	23	11
Total observed errors	46	22
Observed errors per participant	6.6	4.4

Table . Task completion by assistance level.

Task and subtask	Test 1 (n=7)	Test 2 (n=5)
Task 1: plan a 1-way trip	• CI[a]: 4 (57%) • CA[b]: 3 (43%) • NC[c]: 0 (0%)	• CI: 2 (40%) • CA: 2 (40%) • NC: 1 (20%)
Task 2a: create profile	• CI: 5 (71%) • CA: 1 (14%) • NC: 1 (14%)	• CI: 3 (60%) • CA: 2 (40%) • NC: 0 (0%)
Task 2b: personalize profile	• CI: 0 (0%) • CA: 4 (57%) • NC: 3 (43%)	• CI: 3 (60%) • CA: 2 (40%) • NC: 0 (0%)
Task 3a: plan a trip	• CI: 2 (29%) • CA: 3 (43%) • NC: 2 (29%)	• CI: 4 (80%) • CA: 1 (20%) • NC: 0 (0%)
Task 3b: use personalized profile information	• CI: 5 (71%) • CA: 0 (0%) • NC: 2 (29%)	• CI: 5 (100%) • CA: 0 (0%) • NC: 0 (0%)
Task 3c: plan a return trip	• CI: 3 (43%) • CA: 3 (43%) • NC: 1 (14%)	• CI: 3 (60%) • CA: 2 (40%) • NC: 0 (0%)
Task 3d: save or print	• CI: 5 (71%) • CA: 1 (14%) • NC: 1 (14%)	• CI: 4 (80%) • CA: 1 (20%) • NC: 0 (0%)

[a]CI: completed independently.

[b]CA: completed with assistance.

[c]NC: not completed.

Efficiency (task duration) remained relatively consistent between the 2 tests, with a mean of 7 minutes and 48 seconds for T1 and 8 minutes and 35 seconds for T2. Overall, test 2 descriptively suggested fewer observed errors per participant and higher task completion, with similar efficiency; however, these findings should be interpreted cautiously, given the small and nonequivalent participant groups.

Questionnaires

The mean SUS score rose from 54.6 (SD 21.2; median 57.5) to 81.5 (SD 12.6; median 82.5) between the first and second tests, shifting the interface rating from "unacceptable" to "very good" [48]. Overall, the SUS results descriptively suggest higher perceived usability after the design revisions, suggesting that these revisions improved the user experience. Mean scores of UTAUT were descriptively higher across all constructs in test

XSL•FO
RenderX

2 (n=5) than in test 1 (n=7), with Social Influence remaining the lowest-rated construct in both tests (Table 4).

Table . UTAUT[a] scores from the first and second laboratory usability tests.

Test	Performance expectancy	Effort expectancy	Facilitating conditions	Behavioral intention	Behavioral use	Social influence
Test 1, mean (SD)	3.9 (0.7)	3.6 (1.2)	3.6 (0.8)	3.1 (1.4)	3.9 (1.4)	1.9 (1.0)
Test 2, mean (SD)	4.6 (1.1)	4.5 (1.4)	4.3 (0.6)	4.1 (0.8)	4.3 (0.7)	3.0 (1.1)

[a]UTAUT: Unified Theory of Acceptance and Use of Technology.

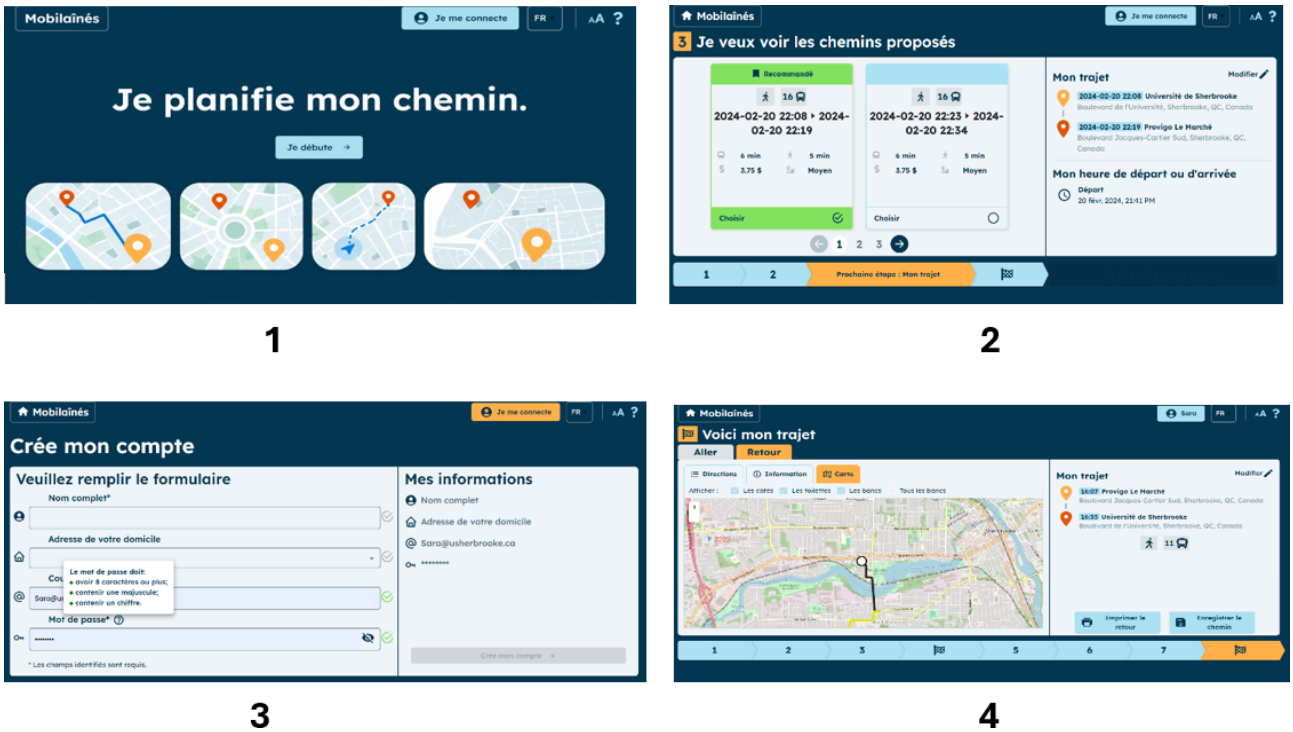
Focus Group Discussion

Following the 2 laboratory usability tests, participants shared valuable feedback during group discussions, which was thematically organized according to age-friendly usability design principles: Ease of Use, Structure and Navigation, Feedback, Control, Information, Simplicity, Visual Clarity, Consistency, and Accessibility (Table 5). Participants' quotes from the laboratory usability tests were translated from French into English.

XSL•FO
RenderX

Table . Themes identified from the focus groups of the first and second usability tests.

Themes and subthemes (tests 1 and 2)	Examples of quotations
Ease of use	
Lack of automatic data entry (T1)	"I spent half the time having the right password then the email, it didn't work. I started again, I started again, I started again" [P6, T1].
Easy to use (T2)	"I thought it [Mobilaînés] was very good because there wasn't too much information; you had to go into it" [P5, T2].
Structure and navigation	
Difficulty in navigation (T1 and T2)	"While I was engaged, I often felt lost on the pages, unsure of how to proceed. I knew what I wanted to do, but I couldn't figure out where to do it" [P2, T1].
Lack of using drop-down menu (T1)	"The drop-down menu was missing; when I searched for Sherbrooke, the result stayed behind the loading wheel. Usually, on the Internet, there is a small menu" [P3, T1].
Lack of visual or textual assistance (T1)	"I actually wish there were arrows" [P6, T1].
Feedback	
Lack of confirmation (T1 and T2)	"It was not easy to know when you finished the task" [P1, T1].
Lack of relevant feedback in error (T1 and T2)	"The little circle that turned, turned, turned, then gave nothing. Meanwhile, the minutes pass. I actually panicked a little" [P1, T1].
Confirmation in performing an action (T1 and T2)	"It is certain that if you use the Sherbrooke transportation system website [...] it does not ask us to confirm the new one. If our direction is correct, we know it's [new address] correct [...]" [P1, T2].
Control	
Lack of control by undoing, redoing, and saving (T1 and T2)	"Once I had one error in the go trip or round trip, I had to go back to the option at the top [...] it took me a while to figure out" [P7, T1].
The possibility of enlarging the maps (T1)	"I was happy to see there were maps. I love that. But I haven't tried to see if we can bring it closer because sometimes, I like to know where the stops [bus stations] are. I like to zoom in a little to see a little" [P6, T1].
Lack of safety in protecting the personal information (T2)	"Personally, I don't go into profiles there, I'm always afraid of having my identity stolen [...] There is no recall [to change the password] [...]" [P4, T2].
Information	
Insufficient relevant information for address searches, age-related travel discounts, purchasing travel tickets, checking route conditions, and comparing different modes of transport (T1 and T2)	"I wouldn't have known about the discount pass without my sister; it would help to integrate practical information like that" [P7, T1].
Lack of real-time travel information (T1 and T2)	"The advantage of Transit is that it provides real-time updates [...] That's the challenge I often face: the lack of real-time awareness" [P7, T1].
Simplicity	
Lack of clarity in terminology (T1)	"About the words used when we talk about Arrive/departure, I didn't know if it meant starting when I was performing the tasks. I was like that the more I progressed" [P3, T1].
Clarity in terminology (T1)	"About the words arrive/departure, I like it, because the departure from or arrival for that is important too" [P6, T1].
Visual clarity	
Lack of accompanying the text with images for better perception (T1)	"There are programs where when you approach the menu like personal information a small explanatory window opens" [P7, T1].
Readable font size (T1)	"Is this the real size of what will appear? Let's say I'm on a computer. Do the writings stay big like that? I think it [font size] is okay" [P3, T1].
Lack of visual clarity in the size of text and icon (T2)	"The little instruction sign was very small" [P4, T2].
Lack of clarity in color contrast (T2)	"You need to put such type of character [color of text] or such color of character on a dark background" [P1, T2].
Consistency	



XSL•FO
RenderX

Themes and subthemes (tests 1 and 2)	Examples of quotations
Lack of using familiar buttons, icons, or information (T1 and T2)	"I always wanted to press 'Enter,' but there wasn't there [...]" [P4, T1].
Lack of presenting the information in a familiar framework and structure (T1)	"It was the American 2 am system. In Quebec, we use 14h for the afternoon" [P4, T2].
Inconsistency in navigation structure (T2)	"Maybe it would be better to put a next button instead of it [the buttons at the end of the page]" [P5, T2].
Accessibility	
Possibility of planning a trip for the future (T1)	"If you want to plan a trip for tomorrow afternoon, that's not possible. All it gives you is leave now" [P1, T1].
Lack of adaptation to the preferences of different groups of users (T2)	"Then it [Mobilaînés] didn't want me to take the bus, it forced me to walk. I think that's ageism" [P5, T2].
Adaptation to the preferences of different user groups (T2)	"Totally, I should say there is a word in English, I think it [Mobilaînés] is user-friendly" [P3, T2].
Consistency with other transport planning e-tools (T2)	"I found that it was an application that worked in much the same way as other websites. The fact that we weren't in a completely unknown universe is an advantage of it [Mobilaînés]" [P4, T2].
Possibility of personalizing the account (T2)	"Transit you can't create an account, you always have to fill in what you want, same for Google Maps" [P5, T2].
Accessible and age-friendly transport planning website (T2)	"Totally, the Mobilaînés was good, it was pleasant. There was always something of a discovery there. But it wasn't brilliant, but overall, it was pleasant" [P4, T2].

Across both laboratory sessions, participants encountered similar usability issues, mainly related to navigation, feedback, and data entry. Error analysis informed several refinements before test 2, including clearer confirmation messages and feedback (number 1 in Figure 3); clearer step indicators (number 2 in Figure 3); simplified password guidance (number 3 in Figure 3); renamed tabs, larger navigation arrows, improved map icons, and route controls (number 4 in Figure 3); and refinements to account creation and personalization features. Although real-time updates could not be implemented because of budget constraints, these revisions improved usability and prepared the interface for in-field testing.

In the laboratory usability evaluations, Mobilaînés' compatibility with age-friendly design guidelines increased descriptively from 72% to 84%. Remaining issues involved color contrast, scroll bars, lack of autofill, limited feedback and control features, unfamiliar presentation of new information, and missing real-time travel updates.

Figure 3. Mobilaînés website interface used for the second usability test.

XSL•FO
RenderX

In-Field Test

Overview of the in-Field Test

Over 6 weeks, participants used Mobilaînés for daily trip planning. During week 1, meeting dates and locations were arranged in Sherbrooke, with 1 adjustment for a participant with limited transit experience. Two participants matching the Léonard persona required targeted support due to technical difficulties, including unfamiliarity with Google Chrome and forgetting how to use the tool. Attractiveness, Perspicuity, Efficiency, and Dependability scores were higher in the second UEQ assessment, while Stimulation and Novelty were slightly higher in the first assessment (Table 6).

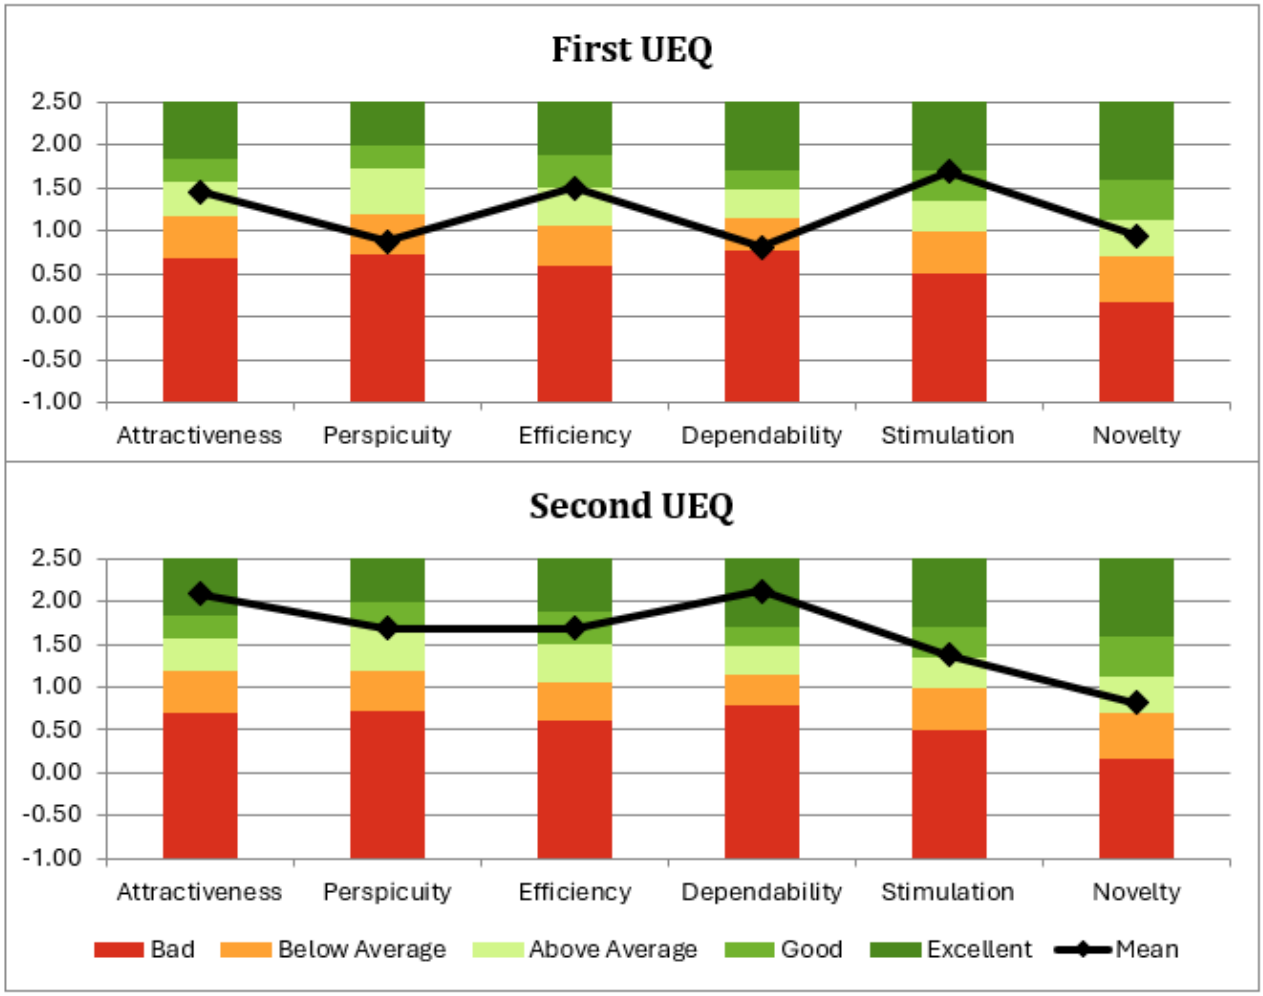


Table . Scale means and SDs of the first and second UEQ[a] assessments.

UEQ scale	First UEQ, mean (SD)	Second UEQ, mean (SD)
Attractiveness	1.46 (0.91)	2.08 (1.13)
Perspicuity	0.88 (0.48)	1.69 (1.13)
Efficiency	1.50 (0.54)	1.69 (1.09)
Dependability	0.81 (0.90)	2.13 (0.85)
Stimulation	1.69 (1.07)	1.38 (1.18)
Novelty	0.94 (1.30)	0.81 (1.84)

[a]UEQ: User Experience Questionnaire.

Comparison of the UEQ scores with the standardized benchmark dataset revealed that Stimulation consistently ranked in the top 25% (good) across both assessments, while Novelty remained in the top 50% (above average). Efficiency and Attractiveness scores increased from the top 50% (above average) to the top 25% (good) and top 10% (excellent), respectively. Dependability and Perspicuity showed the greatest improvement, moving from the bottom 50% (below average) to the top 10% (excellent) and top 50% (above average), respectively (Figure 4).

Figure 4. UEQ benchmark comparison for the Mobilaînés e-tool: first vs second assessment. UEQ: User Experience Questionnaire.

RenderX

Interviews

A total of 14 subthemes were identified and classified into 9 key themes (Table 7). Five of these themes reflected positive content, including ease of use, an age-friendly travel-planning process, tailored and optimal route options, accurate timing and information, and reliability.

Table . Themes and subthemes identified through the in-field test interview.

Themes and subthemes	Examples of quotations
Ease of use	
• Easy to navigate and functional e-tool for travel planning • Easy-to-use systematic travel-planning process	"I find that although Mobilaînés has more steps, each window focuses me on a specific question [...] so I do give Mobilaînés more stars [...]" [P3].
Absence of real-time and traffic information	
• Lack of real-time travel and traffic information	"[...] for planning, I would use Mobilaînés. For the actual travel time, I would give the advantage to Google Maps because it provides real-time bus stop information, and I would know where I am [...] if Mobilaînés had real-time information, I would still use Mobilaînés first for planning [...]" [P3].
Age-friendly travel-planning process	
• Easy and accessible possibility of planning a round-trip • Detailed information provided on the path, which navigates users in the routing process.	"I used to use Google Maps, but [...] I prefer Mobilaînés because it provides more of what I expect [...]" [P2].
Tailored and optimal route options	
• Route options more tailored to user needs and preferences • Different route options in travel planning	"[...] anytime I've compared Mobilaînés to Google Maps for the proposed bus routes, they've always been the same, or Mobilaînés has been at least as good, if not better. [...] So, it was the best options were provided by Mobilaînés. [...] I would look at Mobilaînés and for going to new locations" [P3].
Accurate timing and information	
• Accurate and precise travel-related information • Accurate timing in travel planning	"It encouraged me to go out more. [...] The mobile app would show me exactly what time to take the bus to Carrefour. [...] So, you could say that the timing information on the website is one of the motivators [...]" [P2].
Reliability	
• Mobilaînés is reliable for going to new places • Mobilaînés is reliable for going out independently	"The first time I was very, very apprehensive [...] But now no problem. Now I feel comfortable, and I trust it" [P4].
Lack of accuracy in navigation	
• Mobilaînés is not that reliable in walking as it sometimes shows the wrong path	"[...] that was the main bug for me [...] it was always having me go in the wrong direction or not in the proper route [...]" [P3].
Absence of pertinent feedback	
• Lack of feedback in displaying the error message	"When you put the time around noon, forget it. [...] At one time, I could not print. [...] It's okay that that [printing error] happened only once" [P4].
Necessity to minimize walking time	
• Lack of possibility of saving the walking time	"[...] For me, it's not a problem, but for an older person [...] it will take a long time to get to the bus. [...] for people who are not used to walking, it's difficult [...]" [P1].

In sum, the in-field usability evaluation suggested that the iterative co-design and testing process led to an interface largely aligned with age-friendly guidelines, reaching 95% compatibility. Key design decisions included maintaining a step-by-step travel-planning process, presenting structured route information, supporting personalization of travel preferences, and improving visual cues and feedback. These design changes appeared to support participants' confidence and perceived reliability of the e-tool in real-world travel planning. Remaining issues included inconsistent presentation of new information, limited simplification of some travel data, lack of real-time travel and traffic information, and technical problems such as poor error handling and incorrect time displays. These issues were forwarded to the development team for correction.

Discussion

Principal Findings

This study sought to enhance the experience of older adults using a transportation planning e-tool by developing an interface

XSL•FO
RenderX

grounded in their needs and preferences through a participatory approach. The process focused on 2 objectives: co-designing an interface with older adults and evaluating its usability and user experience. The compatibility of the Mobilaînés e-tool with age-friendly design guidelines increased descriptively from 67% to 95% through iterative mock-up development and usability tests. These improvements were reflected in user experience scores, moving from unacceptable to very good.

The compatibility of the Mobilaînés e-tool with age-friendly heuristics aligns with findings by Patsoule and Koutsabasis [54], who identified Visibility and Ease of Understanding as the 2 primary heuristics tailored to older adults in website redesign. A clear and intuitive interface can significantly reduce cognitive load for older adults when interacting with digital tools, making tasks more manageable and less stressful [55]. Our results are also in line with those of Hart et al [47], who suggested that improvements to increase design compatibility with guidelines contributed to a more user-friendly experience for older adults. In our study, in-field test participants expressed a high level of satisfaction with the website's interface, which was easy to use and well suited to their travel planning needs. UEQ results showed that after several weeks of use, participants found the Mobilaînés e-tool more interesting, practical, and easy to use for travel planning. With repeated use, they also perceived it as more attractive, efficient, and trustworthy, encouraging more spontaneous and sustained engagement. However, one participant noted the absence of real-time travel and traffic information, which would have allowed tracking of their bus journey and arrival times. This limitation was observed across all 3 usability evaluations and relates to the *Information* principle in usability design guidelines. Although the travel plan printing feature does not offer real-time updates, its visual and informative format ensures accessibility for all older adults, regardless of digital proficiency. For older adults who may experience heightened anxiety from unexpected travel disruptions, Citroen [56] emphasizes that access to up-to-date information can significantly reduce stress and improve decision-making. Incorporating such features not only enhances the tool's practicality but also strengthens user confidence and satisfaction—key factors in promoting adoption and sustained use.

Interpreted through the UTAUT model [49], the design refinements implemented in Mobilaînés may help explain improvements in usability and acceptance. Step-by-step navigation, simplified task flow, familiar terminology, and clearer feedback may have supported effort expectancy by reducing the perceived difficulty of use. Personalized route-planning options, such as saved addresses and walking preferences, may have strengthened performance expectancy by making the tool more useful for users' everyday travel needs. Clear structured guidance may also represent facilitating conditions by helping users complete tasks with greater confidence. From a behavior change perspective [57], these features may support perceived capability and confidence in planning trips independently, which may encourage future use and engagement in community mobility.

However, achieving these improvements required several design and evaluation cycles, highlighting the time and resources needed to develop age-friendly e-tools through participatory and iterative approaches [58]. Qualitative data further highlighted the tool's reliability, accessibility, and effectiveness for transportation planning, despite limitations such as the absence of real-time data. Overall, these findings emphasize the value of involving older adults throughout the design and evaluation process to ensure that the Mobilaînés e-tool is closely attuned to their lived experiences and everyday contexts [58,59].

The in-field test results further revealed that Mobilaînés reduced participants' travel-related concerns by helping them anticipate each step of their journey and boosting their confidence in reaching unfamiliar destinations or adopting new modes of transport, particularly when transitioning away from car use. Although the destinations and usage period of the Mobilaînés tool were predetermined, participants reported that it enhanced trip predictability and served as a reliable resource for leaving their homes independently. In line with behavior change theory [57] and the Technology Acceptance Model [60], generating positive emotions, such as feeling safe and anticipating the pleasure of reaching a destination, may encourage sustained use of Mobilaînés. Greater ease of use enhances the overall experience, which can in turn support older adults' independence, social participation, and overall quality of life [61]. According to Schroeder et al [62], older adults' intention to adopt technology is notably influenced by awareness, emotional needs, and motivational aspects. Understanding these motivators is essential, as personal desire drives activities such as visiting family, whereas medical appointments are often perceived as obligatory [63]. This finding highlights the potential of Mobilaînés to not only facilitate independent mobility but also foster sustained engagement in meaningful daily activities by aligning technological support with older adults' emotional and motivational needs.

The main contribution of this study is not limited to the development of a transportation planning e-tool; rather, it lies in generating practical design lessons for age-friendly transportation planning interfaces. Through an iterative co-design and evaluation process, this study identifies concrete design decisions related to navigation, feedback, visual clarity, personalization, and route information that can inform the development of future digital transportation tools for older adults.

Limitations

This study faced several limitations. First, recruitment challenges resulted in an overrepresentation of tech-savvy participants (Solange personas) and an underrepresentation of those with lower digital literacy (Leonard and René personas). This imbalance may have influenced usability outcomes and should be considered when interpreting the findings. The use of personas also requires caution, as they can simplify the diversity of older adults' experiences if they are not continuously grounded in lived experience. In this study, personas were developed based on interviews, literature, and stakeholder workshops, and were used as design tools to guide recruitment, scenario development, and interface decisions. However, the overrepresentation of participants corresponding to the Solange persona may have influenced design priorities, limiting the

XSL•FO
RenderX

representation of other mobility and digital literacy profiles. Additionally, the small sample size in the laboratory usability tests (n=5 and 7) and particularly in the in-field test (n=4) warrants caution regarding the generalizability and transferability of the findings. The in-field results should therefore be interpreted as exploratory, providing preliminary insight into real-world use rather than definitive evidence of sustained effectiveness. Moreover, comparisons between the 2 laboratory usability tests should be interpreted descriptively, as they involved different participants and participant profiles, with the second test including only those participants corresponding to the Solange persona. Therefore, observed improvements in performance metrics, SUS, UTAUT, and UEQ scores may reflect both interface refinements and differences in participant characteristics, rather than generalizable evidence of effectiveness. Several strategies were used to promote recruitment, such as online advertisements, poster distribution, and the use of local databases. However, given the risks of fraud associated with soliciting older adults by phone or online [64], recruitment through trusted individuals or community partners may be particularly important in future studies [65]. Moreover, flexible scheduling regarding time and place helped to reduce withdrawal due to health reasons, which is common in participatory approaches involving older adults [66,67].

Second, resource constraints affected the feasibility of conducting a broader summative evaluation, such as involving multiple independent evaluators for heuristic analysis. The iterative co-design process required more design and evaluation cycles than anticipated, creating challenges related to time, resources, and project continuity. This highlights the need to plan sufficient resources and procedural continuity from the outset, as the number of refinement cycles can be difficult to predict. To support methodological rigor, usability issues were reviewed with interdisciplinary team members during key development and evaluation phases to help reduce interpretation bias [68]. Design issues were prioritized according to their relevance to age-friendly usability principles, potential impact on task completion and user experience, and feasibility within project constraints.

From a reflexivity and positionality perspective, the analysis and design decisions were shaped by an interdisciplinary team with expertise in user experience, rehabilitation, gerontology, communication, and computer science. While this positioning supported a multidimensional interpretation of the findings, it may also have influenced how usability issues were identified and prioritized. To reduce this risk, interpretations were informed by multiple sources of evidence, including heuristic evaluation results, older adults' feedback, performance metrics, questionnaire results, focus groups, and interviews.

Future Studies

Future studies should address key challenges identified during the development and evaluation of the Mobilaînés application. First, integrating real-time travel and traffic data is essential for effective trip planning [69], reducing anxiety about getting lost [10], protecting against adverse weather and traffic [70,71], and supporting transport choices aligned with individual needs [72]. Features not yet implemented, such as avoiding icy roads, could be enhanced through technical solutions and partnerships, improving adaptation to real-life mobility challenges and addressing safety concerns for pedestrians using mobility devices in winter conditions [73-75].

Second, future research should examine design approaches that support adoption and long-term routinization among older adults with diverse mobility, social participation, and digital literacy profiles. Interview and focus group findings suggested that accessibility features, such as pairing icons with text labels and using familiar visual cues, may benefit all users while supporting age-related visual decline and novice users, such as those represented by the René and Suzana personas. Older adults' technology adoption is shaped by prior experience, available support, perceived usefulness, confidence, and comfort [21]. For Mobilaînés, these factors may involve reliability, accurate real-time and offline information, auditory guidance, and cues that provide ongoing support or training. Universally accessible systems responsive to older adults' needs can improve usability and user experience, thereby encouraging adoption and sustained engagement [76,77]. Finally, future studies should include longitudinal evaluations of spontaneous and sustained real-world use beyond structured, researcher-supported testing to assess long-term impacts on meaningful activities, gradual behavioral changes, and infrequent travel needs, such as medical appointments.

Conclusions

Given the aging population and the critical role of mobility in health outcomes [78], this study addresses a key knowledge gap by advancing age-friendly digital transport planning. Using a participatory approach, the Mobilaînés e-tool was developed and evaluated with older adults to ensure that the interface aligned with their needs and preferences. A key contribution of this study is the identification of concrete design improvements, such as step-by-step task flow, clearer navigation, enhanced visual cues and feedback, structured route information, and personalization of travel preferences that support a more age-friendly planning experience. Findings highlight the need for iterative refinement to reduce cognitive load, support meaningful engagement, and promote digital inclusion, while guiding the development of accessible transport technologies for older adults. Future research should examine human-centered and technological strategies to foster adoption and sustained use, particularly among users with limited digital literacy.

Acknowledgments

The authors gratefully acknowledge the older adults and lived experience contributors, especially Line Coutu, citizen member of the steering committee, and Sylvie Lebrun, director of the Seniors' Consultation Table, for their participation. They also thank

Abstract

Background: Telemonitoring offers solutions for remote health management among older adults; yet, acceptance varies based on individual perceptions and presentation strategies.

Objective: This 2-phased sequential mixed methods study examines the role of message framing on telemonitoring adoption among low-income older adults.

Methods: Phase 1 involved in-depth interviews with 17 older adults, identifying key facilitators (accessibility, affordability, and health benefits) and barriers (preference for in-person consultations, technological limitations, and information processing difficulties) of telemonitoring. Building on these insights, phase 2 used an experimental study with 120 participants assessing message framing effects (episodic vs thematic) and modalities (video vs photo-text) on telemonitoring adoption.

Results: Episodic framing did not produce a significant main effect on attitudes toward telemonitoring; however, its effect was moderated by external locus of control (LOC), with episodic framing associated with more positive attitudes among participants lower in external LOC, and thematic framing more favorable among those higher in external LOC.

Conclusions: Convenience, cost, and health benefits emerged as key adoption drivers, while traditional consultation preferences and cognitive processing challenges posed barriers. Theoretical and practical implications were discussed.

KEYWORDS

telemonitoring; older adults; health communication; message framing; digital inequality; aging in place

Introduction

Background

Telemonitoring uses electronic technology to remotely track patients' vital signs and health parameters [1]. By enabling continuous monitoring, telemonitoring facilitates early detection of health changes and supports "aging in place," enabling older adults to live in their communities safely and independently [2,3]. However, telemonitoring services are not equitably accessible due to communication inequalities (disparities in access to and use of ITs), particularly among socioeconomically vulnerable groups [4]. Older adults face greater obstacles in receiving virtual care due to limited use of digital health technologies, insufficient technological resources, and lack of motivation [5]. Those with limited financial resources may lack access to necessary devices [6].

To address these gaps, we conducted a sequential mixed methods study grounded in the Structural Influence Model (SIM) and message framing theory. The SIM posits that health behaviors are shaped by social, economic, and environmental contexts [4], while message framing suggests that information presentation influences attitudes and decisions regarding health behaviors [7,8]. Phase 1 used qualitative methods to examine motivations and barriers for telemonitoring adoption among socioeconomically disadvantaged older adults. Phase 2 evaluated the effectiveness of different message framing approaches (episodic vs thematic) and modalities (video vs photo-text) to evoke motivations identified in phase 1 and therefore enhance telemonitoring acceptance, with attention to how health locus of control (LOC) moderates these effects. By investigating both the factors influencing telemonitoring adoption and testing targeted communication strategies, our research aims to contribute to the development of more inclusive and effective telemonitoring interventions that can help bridge the digital

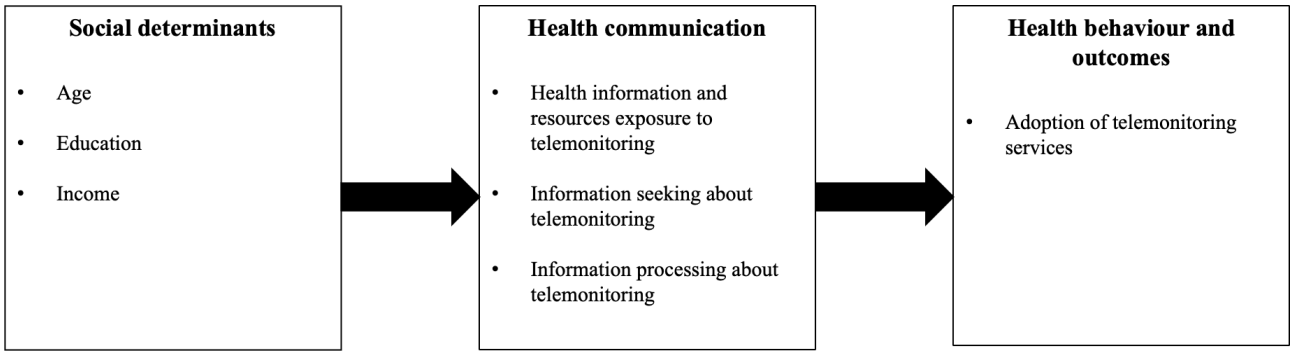
RenderX



divide and improve health outcomes for socioeconomically disadvantaged older adults. This work responds to calls within social gerontology for research that addresses the intersection of technological innovation, social inequality, and the diverse lived experiences of aging [9,10], ultimately supporting the creation of more equitable models of digital health that enhance older adults' agency and quality of life in their preferred living environments.

Theoretical Framework

Structural Influence Model and Phase 1: Exploring Telemonitoring Adoption Among Older Adults

The SIM provides a theoretical framework for understanding how social determinants interact with communication processes to influence health behaviors and outcomes [11]. This model posits that communication outcomes, including exposure, usage, attention, seeking, and processing of health information, are interlinked with social determinants to influence health outcomes (Figure 1). According to SIM, health information benefits are predominantly accessible to those with the capacity to access, process, and use it, highlighting potential for health technologies to widen but not narrow health disparities.

Figure 1. Modified structural influence model in telemonitoring services.

When applied to older adults' engagement with telemonitoring technologies, the model complements the political economy of aging theory [12,13], which emphasizes how socioeconomic structures create and maintain inequalities in later life. Thus, as shown in Figure 1, we adapted Viswanath et al's [11] 4-component framework into a 3-component framework centered on socioeconomic determinants (age, education, and income) and their relationship to health information exposure, seeking, and processing related to telemonitoring. Consistent with SIM, the digital health care revolution may disproportionately benefit those with greater socioeconomic resources, technological skills, and health literacy [14]. Friemel [15] showed that the digital divide persists among seniors, encompassing not just technology access but also differences in usage patterns, skills, and perceived benefits. Research has identified social determinants such as age, income, and education as significant factors influencing telemonitoring adoption [16,17].

Despite existing literature linking social determinants and communication outcomes with digital health adoption, significant gaps persist. Socioeconomic status (SES) complexity necessitates diverse social deprivation measures, tailored to research objectives and cultural contexts. While scholars commonly use income, occupation, and education levels to delineate social standing when exploring health disparities [18], Darin-Mattsson et al [19] suggest that in old age, educational attainment may have a weaker association with health compared to wealth, income, and tenure. These findings underscore the importance of focusing on low-income older adults when examining telemonitoring adoption motivators and barriers. Consequently, guided by SIM, we aimed to address the following research question (RQ):

RQ1: What are the motivators and barriers associated with the adoption of telemonitoring services among low-income older adults, as understood through the lens of information exposure, usage, attention, seeking, and processing?

Phase 2: Message Framing Strategies for Telemonitoring Acceptance

Building upon Phase 1 findings, which highlighted the importance of affordability, convenience, and health benefits, as well as the challenges posed by preferences for in-person consultations, perceived limitations of remote monitoring, and diminished information processing abilities and health LOC beliefs. Phase 2 aimed to develop and test effective communication strategies to enhance telemonitoring adoption. While Phase 1 identified the key drivers of adoption, altering the technology itself or its accessibility through subsidies, redesign, or infrastructure is better addressed through policy or engineering, and falls out of the scope of health communication. Instead, Phase 2 was designed on the premise that user awareness of its benefits and the perceived relevance of those benefits are essential prerequisites for adoption, regardless of a service's objective advantages [20]. That indicates that the critical question is not only whether these benefits exist, but whether they are being communicated in a way that resonates with older adults, as prior research has shown that older adults often fail to recognize the personal relevance of technologies even when aware of their potential benefits [21]. Accordingly, experimental stimuli of 2 modalities held core service information constant across framing conditions, varying only how this information was presented.

XSL•FO
RenderX

Episodic-Thematic Framing in Message Effects

Framing holds particular promise as a major message format studied across diverse health contexts. It involves strategically presented information where attention is drawn toward specific details [8]. In the context of older adults' technology adoption, framing effects can be particularly significant given the experience gap, the discrepancy between older adults' life experiences and new technologies' demands [22]. This gap creates ambiguity about the value and relevance of technologies, making the framing of messages particularly influential in shaping perceptions and attitudes.

Framing theory posits that media messages shape audience perception and interpretation by highlighting particular aspects of an issue [8]. Iyengar [23] proposed an influential distinction between episodic framing and thematic framing. Episodic framing focuses on concrete exemplars, isolating single events or individuals while offering engaging narratives to depict broader issues via unknown and ordinary individuals [23]. Thematic framing focuses on a more societal context while offering statistical evidence. These framing approaches intersect with a sociocognitive perspective on aging, emphasizing how older adults' perceptions, beliefs, and decision-making are shaped by both individual cognitive processes and social contexts [24]. In the health communication context, episodic messages might describe a specific individual's experience with an illness, while thematic messages might present population-level statistics or attribute the issue to broader social factors [25,26]. In this study, the distinction was operationalized as follows: episodic messages featured a personal account from a named older adult regarding their use of health screening services, while thematic messages presented national survey statistics and referenced community health infrastructure (Experimental Stimuli in Methods section).

Findings from Phase 1 showed that only a small number of individuals believed they were fully responsible for their personal health, while the majority displayed a sense of health responsibility attributions to external parties such as the government or medical professionals. This divergence aligns with research in health communication indicating that responsibility for health outcomes is often attributed to a combination of individual and social or systemic factors [27]. Specifically, older adults' sense of health agency often involves negotiating between personal responsibility and reliance on health care systems, particularly as physical vulnerabilities increase with age, consistent with evidence that older adults' perceptions of aging shape their health and functioning [28]. How health messages frame this balance between individual and systemic responsibility may significantly impact their effectiveness. Iyengar's [23] framework was originally designed to explain how episodic and thematic frames shape audience attributions of responsibility for social issues (ie, attributing responsibility to the individual vs society or institutions); thus, it offers a theoretically grounded perspective for examining whether older adults holding differing views on health responsibility resonate differently with these frames.

The distinction between episodic and thematic framing may be closely related to *exemplification theory* [29]. This theory distinguishes between exemplar-based information (ie, vivid and specific cases) and base-rate statistical information, elucidating the cognitive mechanisms underlying their differing effects. According to the theory, exemplar-based information exerts a disproportionate influence on judgment because it is cognitively more accessible and more readily perceived as representative of broader group characteristics compared to abstract statistical data [29]. Recent research strongly supports this effect: a meta-analysis found that across various communication contexts, exposure to exemplar-based information consistently produced stronger effects than exposure to base-rate information [30]; these effects were most pronounced regarding "first-order reality judgments," such as assessments of prevalence or risk [31]. From this perspective, episodic framing can be viewed as a form of exemplar presentation, whereas thematic framing corresponds to the presentation of base-rate information; and this offers a cognitive-mechanism-level complement to explanations regarding the persuasive advantage of episodic framing [32]. These characteristics may make exemplar-based information particularly relevant for some older adults. Age-related declines in information processing capabilities [33], together with a preference for emotionally meaningful and concrete content [34], suggest that older audiences may be especially sensitive to the availability heuristic and representativeness heuristic underlying the exemplar effect. Therefore, we propose the following hypothesis:

H1: Compared to those exposed to thematic framing, older adults exposed to episodic framing report more positive (1) attitudes toward and (2) intention to use telemonitoring services.

Mediating Role of Attitude

Based on Ajzen's [35] Theory of Planned Behavior (TPB), attitude is one of the predictors demonstrating strong and consistent relationships with intention to perform a behavior. This theoretical relationship has particular relevance for older adults given innovation resistance often observed in later life [36]. This resistance isn't merely about technological difficulty but reflects complex attitudinal factors including concerns about privacy, perceived usefulness, and compatibility with existing routines and values [37]. Understanding how attitudes mediate the relationship between message framing and adoption intentions can therefore provide insights into the psychological mechanisms underlying older adults' technology decisions. Similarly, studies have found evidence supporting significant relationships between attitudes and behavioral intentions in the context of telehealth acceptance and COVID-19 vaccination [38-40]. Thus, we posited:

H2: Attitude toward using telemonitoring services is positively associated with intention to use telemonitoring services.

H3: The relationship between framing and intention to use is mediated by attitude toward using telemonitoring services.

Moderating Role of Video and Photo-Text Modality

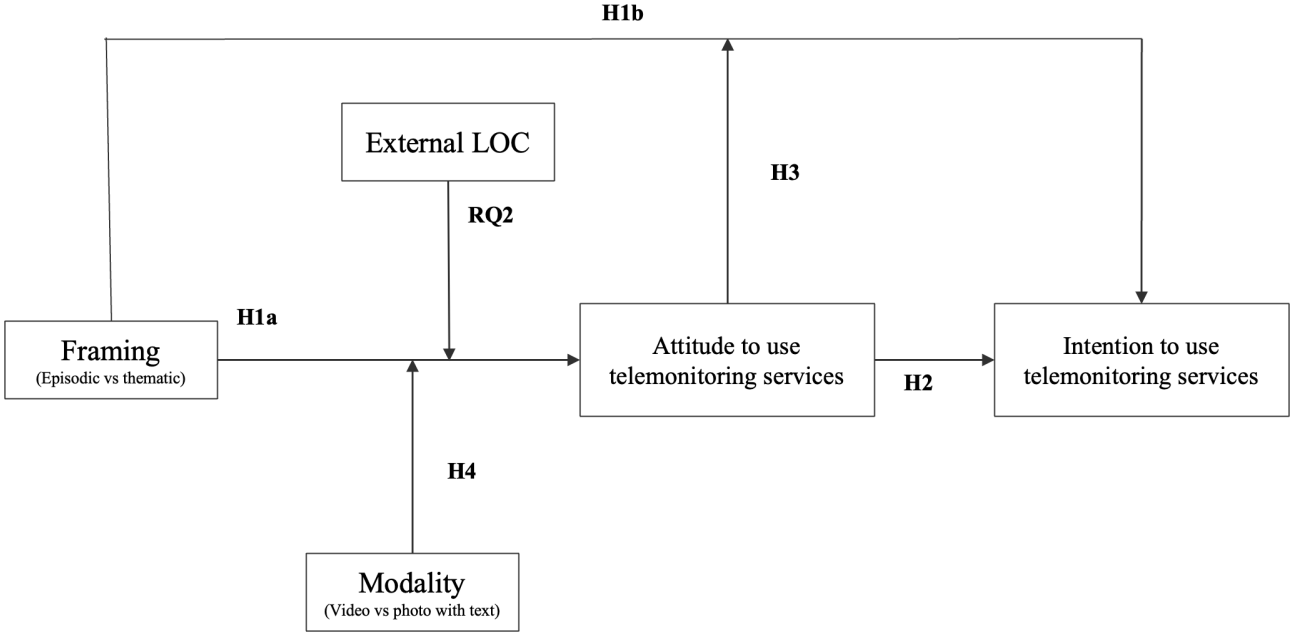
The moderating role of modality suggests the delivery method of messages through media platforms significantly influences message reception [41]. Defined modalities, categorized into video and photo-text, are informed by dual-coding theory [42],

XSL•FO
RenderX

which posits that visual and verbal information is processed by distinct cognitive systems. For older adults, message modality may have heightened importance due to age-related changes in sensory processing and cognitive function. Charness and Boot [43] note that age-related changes in visual and auditory processing can affect how older adults engage with different media formats. This theoretical framework supports that videos, combining visual with conversational elements, can enhance comprehension and retention, making them particularly effective for presenting eHealth information to older adults [44].

Evidence suggests varying impacts based on the chosen modality. One study [45] found that both gain- and loss-framed photo-text stimuli significantly influenced health behavior intentions, whereas another [46] demonstrated that loss-framed videos increased perceived severity of health risks more effectively than gain-framed videos. de Graaf et al [47] and Occa and Suggs [48] highlighted the stronger impact of video messages on health behavior attitudes compared to photo-text modalities. Therefore, we proposed:

H4: Modality and framing would interact, such that participants assigned to the video condition would have a more positive attitude toward using telemonitoring services compared to participants assigned to the photo-text condition.



Moderating Role of External LOC

Wallston et al [49] defined health LOC as the degree to which individuals believe their health is controlled by their own behavior versus external forces. People with an internal LOC believe health status is determined by internal causes such as their own behavior. Meanwhile, those with an external LOC believe that one's health depends on external causes or powerful others such as health professionals. Health LOC intersects with gerontological theories about control beliefs in later life. The selective optimization with compensation model [50] suggests successful aging involves adjusting control strategies as resources and capacities change. External LOC might represent an adaptive response to increasing health challenges rather than simply passive orientation [51]. Prior research supports a strong association between numerous sociodemographic variables and external LOC, with studies finding that those of older age, lower income, and lower education were more external in terms of health LOC [52,53].

Current literature found individuals with a stronger external health LOC are more likely to find thematic framing messages more appealing [54], as they emphasize societal or group responsibility. Similarly, Ceylan and Hayran [55] verified that LOC moderated the effects of prosocial and self-interested messages in following COVID guidelines, where individuals with higher external LOC were more influenced by prosocial messages. In the context of interactive health websites, those with higher external LOC are responding more strongly to vivid, exemplar-rich message formats [56]. However, other studies have shown contrasting or inconclusive results on the link between episodic or thematic framing and individual and societal attributions [57,58]. Hence, the following question was asked:

RQ2: To what extent does external LOC moderate the relationship between framing and attitude toward using telemonitoring services? The proposed research model and hypotheses are presented in Figure 2.

Figure 2. Proposed diagram of the pilot health communication campaign on telemonitoring adoption. H1a: hypothesis 1a; H1b: hypothesis 1b; H2: hypothesis 2; H3: hypothesis 3; H4: hypothesis 4; LOC: locus of control; RQ2: research question 2.

Methods

Research Design

This research used a sequential mixed methods design with 2 phases. Phase 1 conducted qualitative interviews and home observations with older adults to identify key motivators and barriers to telemonitoring adoption through the lens of the SIM. Phase 2 experimentally tested how message framing approaches and modalities might influence telemonitoring acceptance among the target population. This sequential design allowed

XSL•FO
RenderX

development of evidence-based communication strategies informed by the lived experiences.

Ethical Considerations

Overview

The research was conducted with FullHealth (provided by FullHealth Asia), a grassroots initiative that provides telemonitoring services through health screening and monitoring booths (Figure 3). This study received approval from the Institutional Review Board (IRB) of Nanyang Technological University (IRB-2022 - 826). All participants provided written informed consent prior to participation in the study, with protocols designed to accommodate potential age-related needs in the consent process. Before each session, participants were briefed on the study's goals and their participation rights, with consent for audio-recording obtained and anonymity assured through the use of pseudonyms. All data were deidentified by using numerical codes, and any identifying information mentioned in the interview transcripts was removed. The data were stored securely and were accessible only to research team members (DW, HB, APTQ, GHYH, PSH, ESMO, and EWJL). All participants received S$30 (US $23.40) compensation.

Figure 3. FullHealth telemonitoring booth at community venues.

Phase 1: Qualitative Study on Motivators and Barriers

Participants and Sampling

Our research focused on older adults in Singapore, a rapidly aging society where telemonitoring services offer significant potential. We targeted Singaporean adults aged 50 years and older to capture current and future older populations. Participants mainly earned ≤S$3000 (US $2340)/person/month, near the national median of S$3287 (US $2563.86) [59], and included English and Mandarin speakers per census data [60]. We recruited participants through convenience sampling facilitated by FullHealth. We included both users and nonusers of the FullHealth telemonitoring service to capture diverse perspectives.

Data Collection

Data collection was conducted in person in November 2022, using semistructured interviews and observation guides in English and Mandarin. We conducted pilot sessions with older adults familiar with telemonitoring but not participating in the main study to refine the guides for effectiveness while minimizing cognitive burden. Main sessions, facilitated by trained FullHealth volunteers, lasted approximately 90 minutes each (N=17), with appropriate breaks.

Data Analysis

We applied thematic analysis, following Braun and Clarke's [61] guidelines. The last (EWJL) and corresponding (HB) authors independently coded a subset of the data (4/17, 23.53% of participants) through iterative open coding. After comparing findings, discrepancies were resolved through discussion. The remaining data were then independently coded. Cohen Kappa coefficient (κ=0.74) indicated substantial intercoder agreement [62].

Phase 2: Experimental Study on Message Framing

Study Design

We implemented a 2×2 between-subjects experimental design with framing conditions (episodic and thematic) and media formats (video and photo-text), engaging 120 participants from January 16 to February 1, 2023. Participants were recruited using convenience and snowball sampling through FullHealth Asia, referrals, and social media. All participants were unfamiliar with the FullHealth booth.

Experimental Stimuli

Framing conditions: thematic framing highlighted societal issues using "Singapore" in titles, statistical data, national

XSL•FO
RenderX

surveys, and references to older adult activity centers to reflect broader societal concerns. Episodic framing focused on the individual, using direct address (eg, "You"), personal stories, and specific experiences. Both framing approaches ensured clarity for older audiences.

Modalities: Stimuli maintained design consistency through uniform color schemes, fonts, and logos. Photo-text stimuli are provided in Multimedia Appendix 1; the 4 video stimuli are provided in Multimedia Appendices 2-5. Differences were marked by imagery, text, and narration changes for video content, accommodating potential age-related sensory and cognitive changes.

Crucially, the core information of service description, emphasizing that FullHealth's booth was free, convenient, and offers comprehensive health checks (blood sugar, blood pressure, height, weight, heart, and eyes), remained consistent across the episodic and thematic conditions in both the English and Chinese versions. The only difference between the presentation styles lay in the narrative approach used to convey this information (personal narratives vs aggregate statistics combined with organizational background), isolating the framing manipulation from message content.

Procedure

Participants were randomly allocated to 4 conditions: (a) episodic video, (b) episodic photo-text, (c) thematic video, or (d) thematic photo-text. After informed consent, participants assessed external LOC, viewed assigned stimulus, then completed attitude and intention measures plus manipulation checks. A debriefing session clarified any misinformation during the study. Participants received S$15 (US $11.70) as compensation.

Measures

External LOC: this moderating variable was measured using a 5-point Likert scale adapted from the Health Locus of Control Scale (HLCS) by Wallston et al [63], using items such as "Good health is largely a matter of good fortune," with mean 3.13 (SD 0.60, Cronbach α=0.72).

Attitudes toward telemonitoring: participants' attitudes were measured using a 5-point semantic differential scale, with items modified from Dabholkar and Bagozzi [64]. Participants rated their feelings toward using the FullHealth booth on dimensions such as "Good to bad" and "Harmful to beneficial," with mean 4.03 (SD 0.47, Cronbach α=0.85).

Intention to use telemonitoring services*:* this was measured on a 5-point Likert scale, adapted from Boontarig et al [65], with items such as "I intend to use this FullHealth booth in the future," mean 4.14 (SD 0.65, Cronbach α=0.90).

Manipulation check: for framing, participants assessed statements reflecting message focus. Items for episodic framing evaluated FullHealth booth experiences from an individual older adult's perspective, while thematic framing assessment involved societal impacts and statistical evidence. For modality, 2 items checked participants' recognition of the stimulus format (video or photo-text).

Data Analysis

We analyzed the data using Hayes' PROCESS macro (Model 9) [66] via SPSS Statistics (IBM Corp), incorporating gender as a covariate. Because PROCESS estimates a series of ordinary least squares regression equations rather than a simultaneously estimated structural equation model, the coefficients reported below reflect independent regression paths but not a jointly estimated path model; accordingly, global model fit indices (such as χ^2, Comparative Fit Index [CFI], and root-mean-square error of approximation [RMSEA]) are not applicable here. Message framing was the independent variable, with attitudes and intentions toward telemonitoring services as dependent variables. External LOC and modality were considered moderating variables. The complete set of model estimation coefficients (including all covariate, interaction paths, and conditional indirect effects at representative values of the moderators) is detailed in Multimedia Appendix 6, together with bootstrap SE and 95% CI.

Statistical Power

A sensitivity power analysis indicated that, based on the sample size (N=120) and the 6-predictor moderated regression model used to test Hypotheses 1 - 4 and RQ2, the study had 80% power (α=.05) to detect an effect of Cohen $f^2 \geq .067$, an effect size falling between the conventional benchmarks for small (.02) and medium (.15) effects [67]. Post hoc power analyses regarding the key effects reported herein confirm that the study possessed sufficient power to detect the significant "framing× locus of control" interaction (f^2=.095, power=.92) and the relationship between attitudes and intentions (f^2=.173, power>.99). The post hoc statistical power for the main effects of framing, presentation modality, and gender, as well as the "framing× presentation modality" interaction, was relatively low (0.06 - 0.10) (Table 1).

XSL•FO
RenderX

Table . Sensitivity and post hoc power analysis results.

Effect	Observed f^2	Post hoc power
Framing × External LOC[a] → Attitude	0.095	0.918
Attitude → Intention	0.173	0.995
External LOC (main) → Attitude	0.018	0.302
Framing × Modality → Attitude	0.004	0.099
Modality (main) → Attitude	0.002	0.082
Framing (main) → Attitude	0.001	0.058

[a]LOC: locus of control.

Results

Phase 1: Motivators and Barriers to Telemonitoring Adoption

The qualitative phase involved 17 participants, 10 telemonitoring users (denoted by “U”) and 7 nonusers (denoted by “N”), aged 56 - 86 years. Most participants (15/17, 88.2%) had attained education up to A-level or Diploma, while 11.8% (2/17) had no formal education. The majority (14/17, 82.4%) reported monthly income below S$2000 (Table 2). Analysis revealed 3 key motivators, 3 barriers, and 2 influential factors affecting telemonitoring adoption emerged (Figure 4).

Figure 4. Results of motivators and barriers to telemonitoring services adoption.

XSL•FO
RenderX

Key Motivators

Convenience From Close Proximity

Most FullHealth users cited proximity as the primary reason for using the telemonitoring booth, allowing them to "*save time*" (U7, male, 57 years) and:

> *[not] have to travel all the way to [the] polyclinic.* [U8, male, 63 years]

Nonusers also acknowledged "*convenience*" as a potential motivator. Given the observed mobility challenges, convenience appeared to be particularly significant, reflecting how aging-related changes shape technology preferences.

Affordability in Health Care

The "*FOC [Free-of-Charge]*" (U10, Female, 64 years) nature of the booth services encouraged usage among participants. While some noted that the cost advantage might be less significant compared to other subsidized older adult care services (eg, "*This doctor I visit helps me save money. It's not very expensive because I'm old"* [N1, female, 75 years]), comparing the booth with a regular doctors' visit, cost remained critical. When discussing more expensive health services, participants expressed concerns:

> *Of course, it's money problems. Every time also doesn't allow you to cut [medical fees], sum [up] to 37.50 dollars.* [N7, male, 63 years]

Overall, participants demonstrated high price sensitivity, highlighting how financial considerations become increasingly significant in postretirement life.

Enticing Health Benefits

Many participants cited health benefits as a key motivator. These benefits included addressing specific health issues (eg, "*it helps prevent me from getting a stroke again"* [U3, male, 59 years]) and general health monitoring (eg, "*if we have any illness, we will know"* [U8, male, 63 years]). As one participant summarized:

> *In conclusion, [FullHealth Booth] is good for our health.* [U5, male, 86 years]

Participants noted their increased susceptibility to illnesses and, making health monitoring particularly valuable, reflecting how health vigilance increases with advancing age.

Key Barriers

Preference for Face-to-Face Doctor Visits

A primary barrier was the preference for in-person medical consultations. Participants felt that face-to-face meetings provided better understanding of their health concerns (eg, "*Seeing the doctor. Talk about our illnesses [...] clearer. We can understand"* [U4, male, 76 years]; "*When in front of a doctor, if we have any questions, we can ask, which is better"* [U2, male, 57 years]), and offered a sense of familiarity (eg, "*The doctor if we see often already, [we] will go find that doctor"* [N2, female, 78 years]). These preferences highlight how technology adoption in later life is influenced by established relational patterns and trust.

Limited Capabilities of Remote Monitoring

The booth's restricted monitoring capabilities were considered "*very simple*" (U9, male, 65 years) and "*not comprehensive, it's not full*" (N3, female, 56 years), presenting a barrier to adoption. One participant noted:

> *if you go to poly[clinic], one blood test can cross-check a lot of things.* [N3, female, 56 years]

This perception of limited functionality compared to traditional health care services influenced participants' willingness to adopt telemonitoring.

Inadequacies in Information Processing

Information processing posed a major barrier, especially for lower socioeconomic participants who struggled to understand health advertisements (eg,"*[When shown a health advertisement on the National Steps Challenge] also can't really understand when looking"* [N2, female, 78 years]); *"[When asked what the National Steps Challenge Advertisement is talking about] Don't know*" (U8, male, 63 years). Information processing abilities varied notably based on education and income levels. Participant U4 (male, 76 years) with no formal education and earned less than S$1000 per month, demonstrated poor information processing skills (*"[When asked about the TraceTogether Advertisement] never studied, don't understand"* [U4, male, 76 years]). In contrast, participant N3 (female, 56 years), with an O-level certificate and monthly income between S$3000 and S$3999, showed better comprehension (*"[When asked about the TraceTogether Advertisement] To track people where they, in case of Covid, they know who is where, you know, Yeah, so they can trace the people and then inform them that, you know"* [N3, female, 56 years]). These variations highlight how lifelong socioeconomic advantages and disadvantages accumulate to influence technology engagement.

Factors Influencing Information Processing and Telemonitoring Adoption

Value of Information Modality

Participants cited various media sources including "*posters,*" "*pamphlets,*" "*flyers,*" "*radio,*" "*TV,*" "*newspapers,*" "*Facebook,*" "*WhatsApp,*" "*YouTube,*" "*Websites,*" *and "[digital display screens in] lift.*" Although television and mobile phones were the most commonly owned, neither was frequently used by most participants. Multiple media sources were often mentioned (eg, "*I think from the website, [...] flyers, [...] more news"* [N3, female, 56 years]; "*See the news. [...] I buy newspapers [...] Yes, all [Whatsapp and Facebook] got used, also use Youtube"* [U2, male, 57 years]). The diverse media preferences suggested the importance of considering various modalities in health communication.

Underlying Sphere of Control Over Health

Participants displayed varying beliefs about control. Some demonstrated a sense of personal responsibility (eg, "*This [health screenings] is [my] responsibility. If you don't go, then you have a lot of illnesses, then blame who?"* [U5, male, 86 years]); "*For my blood pressure, if it's high, I have to control [it]. If my blood sugar is high, my food intake has to [be] control[led]. I think it's very useful for elderly, people like us*

XSL•FO
RenderX

to take care of our health" (U7, male, 57 years). However, most participants showed a tendency to be influenced by health care providers and government authorities (eg, "*[When asked if the participant wanted to undergo a cataract surgery] I then refute back and say you're a doctor, you then know what, I'm not a doctor how should I know*" [N4, female, 73 years]; "*over there (i.e Chinese medicine clinic) is the volunteer that comes up and helps me do (pump pressure*)" [U3, male, 59 years]). These varying health LOC orientations suggested potential for further investigation (Figure 4).

Phase 2: Effects of Message Framing on Telemonitoring Acceptance

Building on Phase 1 findings, Phase 2 experimentally tested the effects of different message framing approaches and modalities on telemonitoring acceptance. Participants included 79 (65.8%) women and 41 (34.2%) men, with 98 (81.7%) participants earning below S$3000 monthly. Detailed demographics are presented in Table 3.

Manipulation Check

T test analysis for framing manipulation revealed significant differences between episodic (mean 3.67, SD 0.58) and thematic (mean 2.11, SD 0.55) conditions (t_{118}= 15.10; *P*<.001). Similarly, the modality manipulation was successful, with participants correctly identifying their assigned condition, with video: mean 4.11, (SD 0.62) versus photo-text: mean 1.80 (SD 0.53, t_{118}= 22.13; *P*<.001).

Effects of Message Framing on Attitudes and Intentions

Analysis revealed that framing did not exert a significant main effect on attitudes toward telemonitoring services (b=−.03, t_{113}=−0.26; *P*=.80). Consistent with this conditional pattern, the direct effect of framing on intentions to use telemonitoring services also did not reach statistical significance (b=−.01, t_{116}=−0.11; *P*=.91). Participants exposed to episodic framing reported attitudes (mean 4.04, SD 0.52) and intentions to use telemonitoring services (mean 4.14, SD 0.61) broadly similar to those exposed to thematic framing ($mean_{attitudes}$ 4.02, $SD_{attitudes}$ 0.41; $mean_{intentions}$ 4.13, $SD_{intentions}$ 0.58). H1 was therefore not supported as an unconditional hypothesis.

Relationship Between Attitudes and Intentions
